- Polyps
 - Precancerous Conditions, 79-5955
- Teratoid Tumor
 - Neoplasm Metastasis, 79-5919
 - Ultrastructural Study, 79-5919
- Virus, Mumps
 - Immune Response, 79-5954

Oxidoreductases

- Barbituric Acid, 5-Ethyl-5-phenyl-
Liver, Rat Fetus, 79-5638
- Cholanthrene, 3-Methyl-
Liver, Rat Fetus, 79-5638
- p*-Cresol, 2,6-Di-*tert*-butyl-
Microsomes, Liver, 79-5600
- Liver Neoplasms
 - Ceruloplasmin, 79-5998
- Mammary Neoplasms, Experimental
- Ceruloplasmin, 79-5998

Oxygen

- Urea, Ethyl Nitroso-
Hydrogen Bonding, 79-5568

Pancreatic Neoplasms

- Aluminum
 - Occupational Hazard, 79-5939
- Anorexia
 - Diagnosis, Review, 79-5468
- Carcinoma, Ductal
 - Epidemiology, Review, 79-5501
- Ultrasonics

Pancreatic Neoplasms (cont'd)

- Diagnosis, Review, 79-5501

Pancreatitis

- Alcoholic Beverages
- Epidemiology, 79-5972
- Diet
 - Epidemiology, 79-5972

Papilloma

- Alanine, 3-(3,4-Dihydroxyphenyl)-
Nucleotides, Cyclic, 79-5632
- BCG*
 - Nucleotides, Cyclic, 79-5632
- Brain Neoplasms
 - Virus, Polyoma, BK, 79-5791
- Cervix Neoplasms
 - Case Report, 79-5923
- Dibutyl Cyclic AMP
 - Nucleotides, Cyclic, 79-5632
- Esophageal Neoplasms
 - Urea, 3,3-Bis(2-chloroethyl)-1-methyl-
1-nitroso-, 79-5571
 - Urea, 1-(2-Chloroethyl)-3,3-dimethyl-
1-nitroso-, 79-5571
- Skin Neoplasms
 - Benz(a)anthracene, 7,12-Dimethyl-
79-5632, 79-5633
 - Nucleotides, Cyclic, 79-5632
- Stomach Neoplasms
 - Urea, 3,3-Bis(2-chloroethyl)-1-methyl-
1-nitroso-, 79-5571
 - Urea, 1-(2-Chloroethyl)-3,3-diethyl-1-
nitroso-, 79-5571
 - Urea, 1-(2-Chloroethyl)-3,3-dimethyl-
1-nitroso-, 79-5571
 - Urea, 1,3,3-Tris(2-chloroethyl)-1-
nitroso-, 79-5571
- Tongue Neoplasms
 - Benz(a)anthracene, 7,12-Dimethyl-
79-5685
 - Radiation, Ionizing, 79-5685

Paranasal Sinus Neoplasms

- Occupational Hazard
- Epidemiology, Sweden, 79-5601
- Wood
 - Occupational Hazard, 79-5601

Paraproteinemia

- Pyoderma Gangrenosum
- IgG, 79-5840

Paraproteins

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with The Franklin Institute Research Laboratories for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by The Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.
Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)

REVIEW

- 79-6001 Molecular-Biological Aspects of Neoplastic Transformation. (Rus) Shapot, V. S. (Moscow, USSR). *Vestn Akad Med Nauk SSSR* (Groton, CT)(8): 48-55; 1979.

A critical review of current data on the molecular mechanisms of neoplastic transformation is presented. The recent discovery of stable binding of DNA with protein in the chromatin of Zajdela ascites hepatoma cells contradicts the widely accepted hypothesis that derepression of the genome is a universal feature of the cancer cell. It is emphasized that the regulation of nuclear-cytoplasmic transfer of messenger RNA plays an extremely important role in the realization of the oncogenic potential of the cell genome. (64 refs)

- 79-6002 Toxaphene, a Complex Mixture of Polychloroterpenes and a Major Insecticide, Is Mutagenic. (Eng) Hooper, N. K. (Dept. Biochemistry, Univ. California, Berkeley, CA 94720); Ames, B. N.; Saleh, M. A.; Casida, J. E. *Science* 205(4406): 591-593; 1979.

Toxaphene, the most widely used chlorinated insecticide, was mutagenic to *Salmonella typhimurium* strains TA98 and TA100 in the absence of a liver homogenate. This insecticide is a complex mixture (>177 polychloroterpenes) with carcinogenic activity in rodents. Some, but not all, of the mutagenic components were easily separated from the insecticidal ingredients. (26 refs)

- 79-6003 Carcinogenicity of Toxaphene: A Review. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701). *J Toxicol Environ Health* 5(4): 729-748; 1979.

All known studies of the carcinogenicity of toxaphene (TP) are reviewed. TP is highly carcinogenic in rats and mice. It induced malignant neoplasms of the liver in rats. In addition, benign and malignant neoplasms at all sites were increased in male and female rats ingesting TP. Sarcomas were found more often in male rats, carcinomas in female rats. Neoplasms of the endocrine organs were also increased in male and female TP-treated rats. The incidence of neoplasms of the reproductive system was increased in female rats, as was the incidence of mammary gland neoplasms in male rats. Toxic changes in male rats given TP included interstitial fibrosis of the kidney and atrophy of the testes. TP induced malignant neoplasms of the liver in male and female mice. The incidence of malignant neoplasms at all sites was also increased. In addition to hepatic neoplasms, male mice had leukemia or lymphosarcoma, and females had sarcomas of the uterus. (23 refs)

- 79-6004 Are Benzene Effects Limited to the Chromosomal Level? (Eng) Ray, V. (Medical Res. Lab., Pfizer, Inc.). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Of-*

fice of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978. McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 201-206; 1979.

The possibility that the mutagenic effects of benzene are limited to the chromosomal level is reviewed. In tests with and without metabolic activation, benzene did not produce point mutations. At the chromosomal levels, both in vitro and in vivo, benzene was shown to cause chromatid-type breaks, dicentric and ring forms, chromatid deletions, and chromosomal breaks. Of two human studies, one showed no cytogenic effects in 290 persons exposed to benzene over a 10-yr period; the other showed a significant cytogenic effect in 52 exposed individuals, this effect involving chromosome breaks and marker chromosomes. Data obtained in dominant lethal experiments have been negative. (26 refs)

- 79-6005 The Carcinogenic and Other Chronic Effects of Persistent Halogenated Organic Compounds. (Eng) Kimbrough, R. D. (Toxicology Branch, Center Disease Control, Dept. Health, Education and Welfare, Atlanta, GA 30333). *Ann NY Acad Sci* 320: 415-418; 1979.

The chronic effects of persistent halogenated organic compounds are reviewed. These compounds induce mixed function oxidases and cause hepatomegaly in rodents and other mammals. The halogenated dibenzo-dioxins and hexachlorobenzene induce experimental hepatic porphyria, and the polychlorinated biphenyls (PCBs) and technical pentachlorophenyl cause adenofibrosis in rats. Adenofibrosis usually occurs concomitantly with hepatocellular carcinoma in rodents and has also been described in rats exposed to other carcinogens such as *p*-dimethylaminoazobenzene. Hepatocellular tumors have also been reported in rodents after exposure to DDT, dieldrin, mirex, and Kepone, but these compounds do not produce the same type of liver pathology as PCBs. It is not known whether the experimental hepatic porphyria induced by these compounds is in any way related to the induction of hepatocellular carcinoma. Kepone and technical hexachlorobenzene have been reported to cause hyperplasia of the adrenal cortex in rats and quail. All of the above halogenated organic compounds are persistent in biologic systems, but it is not known whether the isomers that persist are the ones that are carcinogenic. Neoplastic nodules are considered to represent part of the spectrum of response elicited by hepatocarcinogens in rodents. All of the halogenated organic compounds may either prevent or enhance tumor induction by other chemicals. Most of these compounds also require activation so that dermal application would not necessarily result in tumor formation. (15 refs)

- 79-6006 Toxicity and Metabolism of Phthalate Esters. (Eng) Daniel, J. W. (Life Science Res., Stock, Essex, CM4 9PE, England). *Toxicol Annu* 3: 257-268; 1979.

The acute, subacute, and chronic toxicities of the phthalate esters, their effects on reproduction, their carcinogenicities and

mutagenicities, the effects of di(2-ethylhexyl)phthalate (DEHP) on hepatic function and enzyme activity, the absorption, tissue distribution, and excretion of DEHP, and the biotransformation of phthalate esters and their effects on cells in culture are reviewed. Chronic feeding studies suggest that the phthalate esters are not tumorigenic, although both DEHP and dimethoxyethyl phthalate were somewhat mutagenic for male mice following ip administration. DEHP and butylglycolylbutyl phthalate also caused significant growth inhibition in human WI-38 cells in culture. (37 refs)

- 79-6007 Formation of Chemically Reactive Metabolites from Drugs. (Eng) Corcoran, G. B. (Dept. Medicine, Lipid Res. Inst., Baylor Coll. Medicine, Houston, TX 77030); Mitchell, J. R.; Vaishnav, Y.; Horning, E. C.; Nelson, S. D. *Adv Pharmacol Ther* 9: 103-111; 1979.

The pathogenetic role of chemically reactive metabolites in drug-induced tissue lesions is reviewed. At least three types of reactive species causing tissue lesions can be postulated: electrophilic cations showing significant glutathione conjugation in vivo; electrophilic cations not showing glutathione conjugation in vivo; and radicals whose toxicity is potentiated by vitamin E-deficient diets. The initial event in the production of a hepatotoxic arylating metabolite of acetaminophen and phenacetin appears to be N-hydroxylation of the parent drug to N-hydroxyacetaminophen (N-HAA), which spontaneously dehydrates to yield acetimidoquinone, a known arylating agent. Data are consistent with a possible base-catalyzed decomposition of N-HAA through the 1,6-elimination of the elements of water to give acetimidoquinone. N-HAA reacts chemically with L-cysteine, N-acetylcysteine, and glutathione. N-HAA was more potent than acetaminophen in producing hepatic necrosis following ip or iv administration to adult male Swiss mice. The data provide strong evidence that N-HAA, in its dehydrated acetimidoquinone form, is the ultimate hepatotoxic metabolite of acetaminophen. (26 refs)

- 79-6008 Concluding Remarks. (Eng) Gillette, J. R. (Lab. Chemical Pharmacology, Natl. Heart, Lung and Blood Inst., NIH, Bethesda, MD 20014). *Adv Pharmacol Ther* 9: 139-148; 1979.

Conclusions regarding the mechanisms of toxicity of compounds such as phenacetin and N-hydroxy-2-acetylaminofluorene are reviewed. Chemically reactive metabolites may be formed by many different reactions catalyzed by several different enzymes. However, a given enzyme may catalyze not only those reactions leading to toxic metabolites but also to those leading to innocuous metabolites. Similar or identical chemically reactive metabolites of a foreign compound may be formed by different pathways, and the effect of changing the activity of the conjugation system depends on which pathway predominates in a given species. A compound frequently decomposes to several different products, and the formation of some of these products may occur through the sequential formation of several chemically reactive intermediates. A given kind of reaction does not always lead to metabolites that are unstable under physiological conditions. The formation and fate of the reactive metabolites of foreign compounds in enzyme preparations depend on both the enzyme composition of the preparation and the cofactors added to it. It appears that chemically reactive metabolites initiate cancer by becoming covalently bound to target purine bases in DNA to form adducts that cannot be properly replicated. Damage to bacterial DNA may apparently occur even when covalent binding of a

mutagen to DNA is low or absent. Thus, much of the correlation observed between mutagenesis and carcinogenesis may be fortuitous. (28 refs)

- 79-6009 Leukemias and Lymphomas Associated with the use of Cytotoxic and Immunosuppressive Drugs. (Eng) Penn, I. (Dept. Surgery, Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80262). *Recent Results Cancer Res* 69: 7-13; 1979.

A prospective survey was conducted of patients in the Denver area to ascertain the incidence and types of leukemias and lymphomas in those groups receiving immunosuppressive therapy in connection with organ transplantation (800 patients, 526 excluding those with nonmelanoma skin cancers and carcinoma in situ of the cervix), and those receiving cytotoxic agents for cancer chemotherapy (321 patients). Recipients of organ transplants were subject to daily azathioprine plus an adrenal steroid or, alternatively, cyclophosphamide, antilymphocyte globulin, splenectomy and thoracic duct drainage. The incidence of lymphomas among the 526 transplant recipients was 32%, compared with 3%-4% in the general population. The lymphomas appeared after an av of 27 mo of treatment (range 2-146 mo), and the predominant type was reticulum cell sarcoma (105 recipients). Hodgkin's disease was relatively rare (3 recipients). The CNS was involved in 42% of patients with non-Kaposi lymphomas. The incidence of leukemias in transplant recipients was not increased significantly by immunosuppressive therapy; leukemias appeared at an av of 57 mo (range 17-154 mo), and the predominant type was chronic or acute myeloid (57% of 21 cases). A total of 333 new tumors developed in the 321 cancer patients receiving antineoplastic therapy (melphalan, cyclophosphamide and busulfan). The new malignancies were predominantly leukemias (52%) and lymphomas (16%). The leukemias appeared an av of 51 mo after chemotherapy, and the majority were acute myeloblastic (46%), acute myelomonoblastic (27%), or acute erythroleukemia (6%). It was not determined whether the lymphomas in the chemotherapy group represented the spontaneous transformation of one malignancy to another type or were complications of therapy. (12 refs)

- 79-6010 Comparison of Carcinogenicity Studies with Aldrin and Dieldrin. (Eng) Ritper, D. L. (Office Pesticide Programs, U.S. Environmental Protection Agency, Washington, DC 20460). *J Assoc Off Anal Chem* 62(4): 900-903; 1979.

The methodologies used in six carcinogenicity studies of aldrin and dieldrin are reviewed and compared. Three of the studies showed essentially no relationship between dietary aldrin-dieldrin and cancer in the albino rat over periods of 2 yr or more. The other three studies, two of which used mice and one of which used rats, showed a positive correlation between aldrin-dieldrin (10-150 ppm, depending on the study) and tumor (benign or malignant) incidence. Cross-comparison of these six studies showed no clear reason why the animals in some experiments developed tumors and those in other experiments did not. Had more information been provided on the external and/or internal parameters of testing, perhaps some otherwise obscure cause and effect relationships in these studies could have been identified. (7 refs)

- 79-6011 The Identification and Control of Occupational Bladder Cancer. (Eng) Parkes, H. G. (Health Res. Unit, British Manufacturers' Assoc. Ltd., Scala House, Holloway Cir-

cus, Birmingham B1 1EQ, England). *IARC Sci Publ* (25): 47-58; 1979.

The discovery, control, prevention, treatment, and compensation of bladder cancer among workers in the British rubber industry are reviewed. Published case reports from many countries suggested the carcinogenicity of 1- or 2-naphthylamine and benzidine early in the 20th century. The carcinogenicity of 2-naphthylamine was established by laboratory experiments in dogs in 1938, yet the production and use of the chemical continued without controls for another 10 yr. A 1958 epidemiological study of the incidence of bladder cancer in rubber industry workers finally led to discontinuation of the manufacture of this chemical. Strict regulations for the manufacture of benzidine were introduced at the same time. In order to prevent industry-induced cancer, continuous epidemiological surveillance is recommended. Follow-up tests of suspected agents in laboratory animals are necessary to identify causal agents. Workers exposed to carcinogens must have the benefit of regular medical screening programs. Computer technology for correlating data on an international scale may allow early identification and recognition of the carcinogenic potential of chemicals in the working environment. (9 refs)

- 79-6012 The Problem of Measurements Near the Limit of Detection. (Eng) Crummett, W. B. (Analytical Lab., Dow Chemical Co., Midland, MI 48640). *Ann NY Acad Sci* 320: 43-47; 1979.

The problems involved in measuring trace impurities and contaminants near the limit of detection are reviewed. One of the most urgent and highly visible problems in product quality is the reduction of the dioxin content in chlorinated phenolic products. Although the presence of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in 2,4,5-trichlorophenol and its derivatives is generally thought to be unavoidable, TCDD has never been conclusively demonstrated in one such derivative, Ronnel. Two highly specific methods have been developed to detect 1 ppb of the carcinogen bis-chloromethyl ether in air. Although a similar method showed the presence of the carcinogen in unsafe quantities whenever formaldehyde and hydrogen chloride were present together in air, a more specific method disproved this finding. Thus, results obtained with the finest equipment and best methods may prove misleading, and the continuous application of the best analytic science is needed to cope with the problems of workplace and environmental contamination. A minimum set of criteria should be developed to assure the integrity of such analytic methodology. Questions designed to help establish precise criteria are presented. These questions relate to methods for sampling, method validation, collaboration, limits of detection, and proof of identity. (18 refs)

- 79-6013 Genetic Effects of Acridine Compounds. (Eng) Nasim, A. (Div. Biological Sciences, Natl. Res. Council Canada, Ottawa, Ontario, Canada); Brychcy, T. *Mutat Res* 65(4): 261-288; 1979.

The biological effects of acridine compounds are reviewed. Acridines and a large number of their derivatives are used in enormous quantities in medicine and industry. The mutagenic activities of these compounds have been demonstrated in many organisms and are known to occur in the dark as well as in the presence of light (photodynamic action). At the molecular level, acridines have been shown to cause frameshift mutations of both the addition

and deletion types. These effects have been of great help in elucidating the nature of the genetic code. Other biological effects of acridines include the inhibition of DNA repair, curing of plasmids, and cell-growth inhibition. (241 refs)

- 79-6014 DNA Binding and Polycyclic Hydrocarbon Carcinogenesis. (Eng) Grover, P. L. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JB, England); Sims, P. *Adv Pharmacol Ther* 9: 13-27; 1979.

The role of DNA binding in polycyclic hydrocarbon (PCH) carcinogenesis is reviewed. The first step in the metabolism of an unsubstituted PCH such as benzo(a)pyrene (BP) is the formation of a simple epoxide, a reaction catalyzed by the NADPH-dependent microsomal monooxygenases. These simple epoxides can then: rearrange nonenzymically to phenols; be hydrated to give dihydrodiols, a reaction catalyzed by microsomal epoxide hydratase; or be conjugated with glutathione, a reaction catalyzed by soluble glutathione transferases. There is evidence that the formation of vicinal diol epoxides is a general mechanism of activation applicable to the PCH's as a class of chemical carcinogens. The most reactive diol epoxides of this type are probably those in which the epoxide grouping is adjacent to a "bay region." The following PCH's are metabolically activated through their conversion of vicinal diol epoxides that react with nucleic acids: BP, benz(a)anthracene, 7-methylbenz(a)anthracene, 7,12-dimethylbenz(a)anthracene, and 3-methylcholanthrene. (82 refs)

- 79-6015 Biological Activity of Polycyclic Hydrocarbon Metabolites and the Bay Region Theory. (Eng) Conney, A. H. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ 07110); Levin, W.; Wood, A. W.; Yagi, H.; Lehr, R. E.; Jerina, D. M. *Adv Pharmacol Ther* 9: 41-52; 1979.

The bay region theory of polycyclic hydrocarbon (PCH) carcinogenesis is reviewed, as are the biological activities of metabolites of benzo(a)pyrene (BP), benz(a)anthracene (BA), dibenz(a,h)anthracene (DBA), and chrysene. The proximate carcinogenic metabolites of BP appear to be BP 7,8-oxide and BP 7,8-dihydrodiol, whereas BP 7,8-diol-9,10-epoxide-2 is an ultimate carcinogenic metabolite in the neonatal mouse. A saturated benzo ring and a bay region 9,10-epoxide group appear to be required for high biological activity of BP. BA 3,4-dihydrodiol is a proximate carcinogenic metabolite of the weak carcinogen BA, and BA 3,4-diol-1,2-epoxide-2 is an ultimate carcinogenic metabolite. The bay region theory predicts that one or more of the DBA 3,4-diol-1,2-epoxides are ultimate carcinogenic metabolites of DBA, and experimental data indicate that the 3,4-dihydrodiol of DBA is significantly tumorigenic for mouse skin and neonatal mice. Chrysene 1,2-dihydrodiol is a proximate carcinogenic metabolite of chrysene, and chrysene 1,2-diol-3,4-epoxide, in which the epoxide group is in the bay region of the molecule, is probably an ultimate carcinogenic metabolite of chrysene. Every hydrocarbon examined to date has been shown to meet the predictions of the bay region theory. (53 refs)

- 79-6016 Carcinogenic Chemicals in the Environment. (Nor) Aune, T. (Miljøtoksikologisk avdeling, Statens Institutt for Folkehelse, Oslo, Norway). *Kjemi* 39(5): 25-29; 1979.

Recent studies on environmental carcinogens are reviewed. The chemical substances known to be carcinogenic in humans include aflatoxins, 4-aminobiphenyl, arsenic compounds, substances occurring in the synthesis of auramine, benzene, benzidine, bis(chloromethyl) ether, cadmium, chloramphenicol, chloromethyl methyl ether, chromium, cyclophosphamide, diethylstilbestrol, isopropyl oils, Melphalan, mustard gas, 2-naphthylamine, nickel, N,N-bis(2-chloroethyl)-2-naphthylamine, oxymetholone, phenacetin, soot, tar, and vinyl chloride. The mutagenicity of cigarette smoke condensate cannot be explained with the presence of benzo(a)pyrene and nitrosamines alone. There are strong indications that the pyrolysis products of proteins and amino acids contribute substantially to the mutagenic effect. It cannot be ruled out that such cocarcinogens as harman and norharman also play an important role. Chemically induced cancer is dose-dependent, even though the dose-response relationship for humans is not yet known for the concentrations that are relevant for human exposure. The fact that a chemical induces cancer in animals or mutations in other test systems is not always sufficient substantiation for the ban of that substance. (6 refs)

- 79-6017 Stereoselective Metabolic Activation of Polycyclic Aromatic Hydrocarbons. (Eng) Jerina, D. M. (Section Oxidation Mechanisms, Lab. Chemistry, Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, NIH, Bethesda, MD 20014); Yagi, H.; Thakker, D. R.; Karle, J. M.; Mah, H. D.; Boyd, D. R.; Gadaginamath, G.; Wood, A. W.; Buening, M.; Chang, R. L.; Levin, W.; Conney, A. H. *Adv Pharmacol Ther* 9: 53-62; 1979.

The most extensively formed and most biologically active stereoisomers of the polycyclic aromatic hydrocarbons are reviewed. The metabolism of benzo(a)pyrene (BP) by rat liver microsomes is highly stereoselective in the formation of (-)-BP 7,8-dihydrodiol, this enantiomer being 5- to 10-fold more potent than the (+)-enantiomer as a tumor initiator and complete carcinogen in CD-1 mice and 10- to 20-fold more active than BP or the (+)-enantiomer in causing pulmonary adenomas and lymphomas in these animals. Of the four possible BP 7,8-diol-9,10-epoxides, the two that are formed most extensively from BP by liver are the two that are found bound to the nucleic acid of the target tissue. One of these isomers, (+)-diol epoxide-2, is 6- to 18-fold more mutagenic for Chinese hamster V79 cells than the other three, and it is more tumorigenic for newborn Swiss-Webster mice. The (-)-enantiomer of BP 4,5-oxide is sixfold more mutagenic toward V79 cells than the (+)-enantiomer. The more tumorigenic (-)-(3R,4R)-enantiomer of benz(a)anthracene is the major enantiomer formed by rat liver microsomes from the parent compound. (36 refs)

- 79-6018 Toxicologic Properties of Fluorescent Whitening Agents. (Eng) Gloxhuber, C. (Henkel KGaA, Dusseldorf, W. Germany); Bloching, H. *Toxicol Annu* 3: 171-203; 1979.

The toxicologic properties of the fluorescent whitening agents (FWA's) used in soaps, detergents, and textile finishing are reviewed. Topics discussed include extent of human exposure; metabolism and excretion; acute and chronic toxicity; dermal irritation; mucous membrane irritation; effects on wound healing; sensitizing properties; phototoxic and photoallergic properties; effects on blood coagulation; estrogenic properties; carcinogenicity; embryotoxicity; and mutagenicity. Few or no changes were observed following repeated sc or po administration of numerous FWA's to cats, rats, rabbits, dogs, or monkeys. Similarly, various

FWA's were noncarcinogenic following po, sc, or topical administration to mice, and none of the compounds tested showed evidence of photocarcinogenicity or teratogenicity. Some FWA's induced petite mutations in *Saccharomyces cerevisiae* in the dark, but none were mutagenic for *Salmonella typhimurium* or warm-blooded animals. No pathologic changes were observed after administration of FWA's to fish, and FWA's did not reach the edible parts of fish. (62 refs)

- 79-6019 Is the Cancer Process Caused by Deletion of One or More Differentiation Genes Normally Activated by Steroid Hormones? (Eng) Money-Kyrle, A. F. (Whetham, Calne, Wilts, England). *Med Hypotheses* 5(9): 987-994; 1979.

The possibility that cancer is caused by the deletion of a gene(s) normally activated by steroid hormones is discussed, and relevant literature is reviewed. It is hypothesized that aflatoxin B₁ and polycyclic hydrocarbon carcinogens cause the deletion of genes necessary for the production of a substance required for the differentiation of the cell and activated by a steroid hormone (possibly a corticosteroid). Such genes could include genes for the production of glutamine transaminase and glutamine synthetase and those involved in vitamin A metabolism. Deletion of any of these genes could cause the cell to remain in an undifferentiated and replicating state. A carcinogen may combine chemically with a gene necessary for cell differentiation, after which a tumor promoter may unmask genes that allow cell division. The gene that had combined chemically with the carcinogen would then be unable to divide; as a result, the progeny would not contain the gene and would be unable to differentiate. (31 refs)

- 79-6020 Metabolic Activation of Chemicals to Reactive Electrophiles: An Overview. (Eng) Miller, J. A. (McArdle Lab. Cancer Res., Center Health Sciences, Univ. Wisconsin, Madison, WI 53706); Miller, E. C. *Adv Pharmacol Ther* 9: 3-12; 1979.

The metabolic activation of chemicals to reactive electrophiles is reviewed. Most chemical carcinogens and most drugs that yield covalent interactions in vivo are unreactive per se and must be activated metabolically to form strong nucleophilic reactants. The electrophilic forms of chemical carcinogens appear to be involved in the initiation of carcinogenesis, and they may also participate in the promotion phase; the same or different metabolites of a complete carcinogen may be involved in these two stages. The metabolism of the following compounds to reactive, mutagenic, and carcinogenic electrophiles is described: aromatic amines, amides, and nitro compounds; aflatoxin B₁; safrole and related allylic benzenes; and ethyl carbamate. (28 refs)

- 79-6021 In Vivo Covalent Binding of Organic Chemicals To DNA as a Quantitative Indicator in the Process of Chemical Carcinogenesis. (Eng) Lutz, W. K. (Inst. Toxicology, Swiss Federal Inst. Technology, Univ. Zurich, CH-8603 Schwerzenbach, Switzerland). *Mutat Res* 65(4): 289-356; 1979.

The use of in vivo covalent binding of organic chemicals to DNA as a quantitative indicator in the process of chemical carcinogenesis is reviewed. A detailed description of the planning and performance of a DNA-binding assay is given, as is a complete literature survey of the in vivo DNA binding of 83 compounds.

REVIEW

The Covalent-binding Index (CBI) is calculated where possible. A list is also provided of 153 compounds that have shown covalent binding to any biological macromolecule in vitro or in vivo. Recent unpublished studies with aflatoxin M₁, macromolecule-bound aflatoxin B₁, stilbestrol, and 1,2-epithiobutyronitrile are included. The CBI for rat-liver DNA showed a surprisingly good quantitative correlation with hepatocarcinogenic potency. Refinements for a DNA-binding assay are proposed, and possibilities and limitations of the use of DNA binding in chemical carcinogenesis are discussed. (295 refs)

- 79-6022 Nutrition and Cancer: A Review. (Eng) Doll, R. (Radcliffe Infirmary, Univ. Oxford, Oxford, England). *Nutr Cancer* 1(3): 35-45; 1979.

The ways in which food and drink can contribute to, or prevent, the development of cancer are reviewed. The consumption of alcohol is associated with an increased risk of cancer of the mouth, pharynx, larynx, and esophagus in many countries, different types of alcoholic beverages sometimes having effects independent of the quantity consumed. Aflatoxin consumption appears to be related to liver cancer, and overnutrition (obesity) is related to cancers of the colon, rectum, breast, and endometrium. The effect, if any, of overnutrition is probably related to the specific effects of individual nutrients. Fat consumption is closely correlated with cancer of the endometrium, breast, and colon, and the consumption of meat, particularly beef, is associated with colon cancer. Vegetables may have a protective effect against colon cancer, as may dietary fiber. It has been hypothesized that differences in diet may act by modifying the bacterial flora in the gut, particularly in one group of clostridia capable of dehydrogenating steroid nuclei. Relative deficiencies of vitamins and trace elements have been suggested as contributing to cancer, and there is some evidence that nitrosatable compounds may contribute to gastric cancer. Bracken fern, which is a common food item in Japan, is associated with esophageal cancer, and smoked and grilled foods may be related to gastric cancer. Neither laboratory nor epidemiological data have linked any food additives to human cancer. (82 refs)

- 79-6023 Chemical Characterization of 465 Known or Suspected Carcinogens and Their Correlation with Mutagenic Activity in the *Salmonella typhimurium* System. (Eng) Rinkus, S. J. (Dept. Preventive Medicine and Community Health, Div. Environmental Toxicology, Univ. Texas Medical Branch, Galveston, TX 77550); Legator, M. S. *Cancer Res* 39(9): 3289-3318; 1979.

The chemical characterization of 465 known and suspected carcinogens is reviewed, as are the mutagenicities of these compounds in the *Salmonella typhimurium* system. No attempt was made to distinguish truly carcinogenic chemicals from promoters and solid-state carcinogens. About 58% of the 465 compounds were adequately tested in *Salmonella*. On the basis of recurring chemical structures, the compounds could be divided into 39 separate categories. The most salient common feature among the 210 compounds that were mutagenic for *Salmonella* was an electrophilicity that was intrinsic to the molecule or introduced by enzymatic modification. Only a few intrinsically electrophilic carcinogens were not active in the *Salmonella* test. Poorly detected categories of carcinogens included: azanaphthols; carbamyls and thiocarbamyls; phenyls; benzodioxoles; polychlorinated aromatics, cyclics, and aliphatics; steroids; antimetabolites; and symmetrical

hydrazines. Nonstandard procedures were necessary to optimize the testing of chemicals that were bactericidal or volatile or that cross-linked DNA. False negatives appeared to arise for two reasons: an inability to devise an in vitro activation system that could be reliably used in a standard way, and an inability to detect the entire spectrum of mutational events that can lead to cancer induction. (255 refs)

- 79-6024 Metabolic Activation of Aminostilbene Derivatives and Diethylstilbestrol. (Eng) Neumann, H. G. (Inst. Pharmacology and Toxicology, Univ. Wurzburg, 87 Wurzburg, W. Germany); Metzler, M. *Adv Pharmacol Ther* 9: 113-122; 1979.

The metabolic activation of aminostilbene derivatives and diethylstilbestrol (DES) is reviewed. α,β -Dihydroxy-acetylaminobenzyl has been identified as the major metabolite of *trans*-4-dimethylaminostilbene (*trans*-DAS), and it was proposed that an epoxide is formed at the stilbene double bond. The metabolic activation of *trans*-DAS appears to be dose-independent, and reactive metabolites are formed in the liver and distributed in the circulation. The evidence suggests that a pharmacokinetic threshold does not exist for *trans*-DAS. Epoxidation of the stilbene bond may also represent a major metabolic pathway for DES. Another major metabolite in most species results from the oxidation of the aliphatic side chain. β -Dienestrol is also a major metabolite in most species. (34 refs)

- 79-6025 The Effects of Exogenous Female Hormones on the Fetus. (Eng) Shapiro, S. (Drug Epidemiology Unit, Boston Univ. Sch. Medicine, 777 Concord Ave., Cambridge, MA 02138); Slone, D. *Epidemiol Rev* 1: 110-123; 1979.

The evidence linking the use of female hormones to various effects in the human fetus is reviewed. These effects include malformations, abortion, prematurity, perinatal mortality, and neoplasia. Clear cell adenocarcinomas of the vagina and cervix in female offspring have been associated with maternal use of diethylstilbestrol (DES) during pregnancy, especially during the first trimester. The incidence of these neoplasms attributable to DES is between 0.1 and 1 per 1,000 up to 22 yr of age. Vaginal epithelial changes in the offspring, including adenosis, have also been associated with DES use by their mothers during pregnancy. There is some evidence that DES use may be associated with testicular cancer in male offspring. There is as yet no more than anecdotal evidence that DES is related to cancers at sites other than the female genital tract in exposed female offspring, and other estrogens and progesterone have not been exonerated in the genesis of clear cell adenocarcinomas in exposed offspring. (66 refs)

- 79-6026 Susceptibility to Cancer and the Influence of Nutrition. (Eng) Sabine, J. R. (Dept. Animal Physiology, Univ. Adelaide, Waite Agricultural Res. Inst., Glen Osmond, S.A. 5064, Australia). *Nutr Cancer* 1(3): 52-57; 1979.

The influence of nutrition on susceptibility to cancer development is reviewed. Experiments, especially those employing animals, designed to relate nutritional factors to cancer incidence must take into account several critical theoretical and practical considerations. At the theoretical level, susceptibility to cancer is a combination of genetic, physiological, and metabolic factors, and any one

or all of these may be influenced by nutritional variables. Similarly, the development of cancer in any one individual is a progressive event and it must be recognized that diet may influence any one or more of these stages. At the practical level, problems can arise because any experiment with animals is also a nutritional experiment; in addition, different answers to the same nutritional question can be obtained simply by choosing different experimental tumor models. Some experiments have shown vitamin A to have a prophylactic and/or therapeutic effect on certain premalignant and malignant lesions, whereas other investigations have shown no correlation between serum vitamin A levels and histologic subtype, extent of disease, or presence or absence of metastases. With regard to dietary fat, experimental data have suggested everything from a close association with cancer etiology to no association. In contrast, the current evidence is generally compatible with the suggestion that there is a fundamental and functional link between cholesterol status, particularly subnormal cholesterol levels, and cancer. It is no longer sufficient just to feed experimental animals and tabulate deaths; the intervening steps must be measured. (17 refs)

- 79-6027 Prolactin and Mammary Cancerigenesis. (Eng) Welsch, C. W. (Dept. Anatomy, Michigan State Univ., E. Lansing, MI 48824); Meites, J. *Prog Cancer Res Ther* 9: 71-92; 1978.

A crucial role for pituitary prolactin in the development and growth of rodent mammary cancers has been demonstrated in several studies. In certain endocrinological states, chronic hyperprolactinemia in susceptible strains of mice and rats can invariably enhance mammary tumorigenesis. In other endocrinological states, hyperprolactinemia can actually inhibit this process in both mice and rats. Chronic hypoprolactinemia, on the other hand, can cause regression of existing rat mammary cancers and, under certain conditions, it can suppress or prevent the development of these neoplasms in mice. Therefore, prolactin is a key hormone during carcinogenesis in the rodent mammary gland. Whether or not prolactin is of significant importance in human breast carcinogenesis remains to be determined. If prolactin can be shown to influence human breast epithelium in a manner similar to its effect on rodent mammary tissue, prophylactic and/or chemotherapeutic control of human breast cancer development may be feasible by appropriate drug-mediated prolactin suppression. - 79-6028 Steroid Hormone Action in Uterine Cancer. (Eng) Takamizawa, H. (Dept. Obstetrics and Gynecology, Chiba Univ. Sch. Medicine, Inohana, Chiba 280, Japan); Sekiya, S. *Prog Cancer Res Ther* 9: 233-247; 1978.

Recent advances in studies of the effects of sex steroids on the development of endometrial carcinoma are reviewed. Unopposed exposure of uterine endometrium to estrogen has been considered a causal factor in the development of adenocarcinoma. Although a carcinogenic potential for estrogen has not been proved, excess extraglandular production of estrone appears to be common in women at high risk for endometrial hyperplasia and carcinoma. Synthetic progestational agents are effective in about one-third of patients with advanced endometrial carcinoma. Direct action by hormones is suggested by in vitro studies, and the effect may be provoked by intracellular receptors, as is observed in normal progenitor cells. Several studies indicate that the progesterone receptor is gradually lost during malignant transformation of the endometrium. (139 refs)

- 79-6029 Diet and Hormones in the Epidemiology of Breast and Endometrial Cancers. (Eng) Armstrong, B. K. (Public Health Dept., Perth, W. Australia). *Nutr Cancer* 1(3): 90-95; 1979.

The roles of diet and hormones in the epidemiology of breast and endometrial cancer are reviewed. These cancers are closely associated geographically, show similar changes in incidence with age, and share some indicators of individual risk. There is evidence that hormones are involved in the etiology of both diseases. Evidence for the association between estrogens and endometrial cancer is strong, but the associations between estrogens, prolactin, and breast cancer are weak. Diet may also be involved in the etiology of breast and endometrial cancers. There may be an association between excess dietary fat and breast cancer risk and between obesity and endometrial cancer risk. Obesity, and therefore excess dietary energy, increases the endogenous production of estrogens. Dietary fat per se may increase both estrogen and prolactin production. It appears likely, therefore, that the influence of diet on the risk of breast and endometrial cancers is mediated through changes in the levels of these hormones. (67 refs)

- 79-6030 Theoretical Mechanisms for Synthesis of Carcinogen-induced Embryonic Proteins. V. The Steroids. (Eng) Hancock, R. L. (High River Inst. Theoretical Cancer Study, High River, Alberta, Canada); Payette, R. *Med Hypotheses* 5(10): 1145-1167; 1979.

The embryonic features of neoplastic cells induced by steroids are reviewed, and a mechanism for this phenomenon is postulated. Estrogen receptor complexes and their effects on chromatin proteins are discussed in detail. A mechanism for the action of estradiol-17- β , in particular for its ability to alter the gene expression (derepression) of mammary gland epithelial cells, is presented. (60 refs)

- 79-6031 A Possible Role of Estrogens in Carcinogenesis of Non-Target Tissues. (Eng) Litvay, M. (75 Kendal Ave., Toronto, Ontario M5R 1L8, Canada). *Med Hypotheses* 5(9): 953-968; 1979.

Information concerning the possible role of estrogens in carcinogenesis of nontarget tissue is reviewed. The mitogenic action of the estrogen-receptor complex is apparently similar in both normal and malignant target tissues. Receptors are also present in several types of non-target tissues, and complexes in those tissues might cause successive mitoses. In normal and malignant cells of the breast and some other types of nonendocrine cells, the ability to produce estrogens from circulating precursors has been demonstrated. These locally formed estrogens might play a role in the initiation of some types of malignant transformation. Indications of such a process include the switching to estrogen production in some neoplastic endocrine or undifferentiated cells; certain ectopic effects displayed by some cancerous tissues; and the existence of evidence that growth hormone, prolactin, and cholesterol are involved in the development of some malignancies. It is hypothesized that the present system for sex hormone synthesis might be an adaptation of a more primitive system in which several cell-types have retained their ability to synthesize these hormones. Polypeptide hormones might evolve from regulatory parts of cyclases or phosphodiesterases. (72 refs)

REVIEW

79-6032 Low-Dose and Species-to-Species Extrapolation for Chemically Induced Carcinogenesis. (Eng) Hoel, D. (Biometry Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC 27709). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978.* McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 135-145; 1979.

Statistical procedures currently used for estimating a low-dose carcinogenic effect in humans based on data from animal studies are reviewed. The mathematical models commonly used to show dose-response relationships generally fall into one of two categories: they may focus on a dichotomous response (eg, the one-hit and probit models); or they may attempt to relate the distribution of the time until occurrence of a given event to dose level (eg, the log-normal and Weibull models). Although the probit and related curves tend to provide similar fits to experimental data, they can generate risk estimates that differ by as much as threefold when extrapolating to incidence rates in the 10^4 and 10^6 range. Thus, it is important to develop a rational basis for selecting among competing extrapolating models. The assumption of linearity of response in the low-dose range appears to be conservative, based on quantitative deductions. The importance of background levels and the manner in which corrections are made for them can have a significant effect on estimated risk. Even greater quantitative errors in risk assessment are probably associated with species scale-up than with the dose-response models. The units in which the dose rate is expressed in the estimation of relative human risk are of great importance. Industrial exposures are generally limited to only a fraction of an individual's total life span, and the manner in which cumulative tumor incidence is adjusted to reflect a lack of lifetime exposure data can significantly alter risk estimates. (7 refs)

79-6033 Setting Tolerances on the Basis of Mathematical Treatment of Dose-Response Data Extrapolated to Low Doses. (Eng) Cornfield, J. (Dept. Statistics, George Washington Univ., Washington, DC); Carlborg, F. W.; Van Ryzin, J. In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977.* Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 143-164; 1978.

The use of dose-response data mathematically extrapolated to low doses for the determination of tolerance levels is reviewed. The dose-response curve derived from the kinetics of a well-understood detoxification reaction is discussed. With such a nonthreshold model, any nonzero dose is treated mathematically as leading to some increased probability of a response. Setting a tolerance requires specifying an acceptable risk. Some standard dose-response curves are discussed, as are the joint effects of many agents and the extrapolation of animal data to human risk. (47 refs)

79-6034 Review of In Vitro Test Systems Using DNA Damage and Repair for Screening of Chemical Carcinogens. (Eng) Williams, G. M. (American Health Foundation Disease Prevention, Naylor Dana Inst., 1 Dana Rd., Valhalla, NY 10595). *J Assoc Off Anal Chem* 62(4): 857-863; 1979.

In vitro test systems using DNA damage and repair for screening chemical carcinogens are reviewed. A mechanistic classification of

chemical carcinogens separates them into two categories: genotoxic (carcinogens that interact directly with DNA), and epigenetic (carcinogens which operate by other mechanisms). Since most in vitro tests for chemical carcinogens have as their indicators some genotoxic effect, not all chemical carcinogens will give positive results in such tests. Also, because no single test detects all genotoxic carcinogens, it is necessary to have a battery of short-term tests. Tests for overall damage are the most broadly sensitive for the detection of DNA damage, but they are redundant when paired with bacterial mutagenesis tests. DNA repair has also been advocated as a screening test, but only excision repair has application to carcinogen screening. The most widely used techniques for monitoring repair measure resynthesis of the excised damaged segments of DNA. Autoradiographic measurement of unscheduled DNA synthesis remains the simplest technique and one for which no failure of correlation with DNA repair has been reported. DNA repair is a greater indicator of damage than cell toxicity or death and would be of greater value as part of a battery of tests. DNA repair is also superior in this respect to the Painter test. The hepatocyte primary culture/DNA repair test has great potential as part of a screening battery. It is broadly sensitive to a variety of structurally different types of carcinogens requiring metabolic activation, and it provides intracellular metabolism in an intact mammalian cell. (64 refs)

79-6035 Cytogenetic Studies and Risk Assessment for Chemicals and Ionizing Radiation. (Eng) Brewen, J. G. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978.* McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 97-115; 1979.

The role of structural chromosome aberrations (SCAs) in risk assessment for chemicals and ionizing radiation is reviewed. SCAs constitute a major component of the genetic damage produced by practically any mutagenic insult in higher eukaryotic systems. Data relating to the molecular mechanism of aberration formation in higher cells can be used for making qualitative and quantitative risk estimates for humans or mice. (27 refs)

79-6036 Overview and Status of In Vitro Transformation. (Eng) Sivak, A. (Bio/Medical Sciences Section, Arthur D. Little, Inc., Cambridge, MA 02140). *J Assoc Off Anal Chem* 62(4): 889-899; 1979.

The status of in vitro transformation assays for the detection of chemical carcinogens is reviewed. In vitro cell culture systems fall generally into three classes: diploid cell strains, Syrian hamster embryo cells; cell lines, mouse BALB/c-3T3 and mouse C3H-10T1/2 cells; and cells plus virus, Fischer rat cells infected with Rauscher leukemia virus and Syrian hamster embryo cells infected with adenovirus. The data accumulated to date show a good correlation between the transformation response in cell culture and the carcinogenicities of chemicals in whole animal studies. The major advantages of the cell culture systems are their relatively small time and cost requirements and their relevance to the carcinogenic process. Their disadvantages are the uncertain nature of the metabolic capabilities of the target cells and the lack of a reliable metabolic activation system that is adaptable for routine bioassays. The development of epithelial cell systems may solve the problem of

carcinogen metabolism as well as provide target cells that are representative of the major organ sites for human cancer. (36 refs)

- 79-6037 Crown Gall Disease. (Eng) Drummond, M. (ARC Unit Nitrogen Fixation, Univ. Sussex, Falmer, Brighton, England). *Nature* 281(5730): 343-347; 1979.

The induction of crown gall disease in plants by *Agrobacterium tumefaciens* is reviewed. *A. tumefaciens* induces this plant tumor by transferring part of a large bacterial plasmid (Ti plasmid) to the plant cells. Crown gall tissue synthesizes opines, which serve as a carbon or nitrogen source for the oncogenic bacteria. The nature of the opine produced is determined by the bacterium and is the one catabolized by the inducing strain. Ti plasmids promote bacterial conjugation and the genes required for their transfer are closely associated with opine metabolism. Experiments with restriction fragments containing T-DNA of an octopine plasmid have shown that the left end of the octopine T-DNA and sequences extending as far as its left-hand boundary are highly conserved on all Ti plasmids. The greater part of the conserved region is found in all tumor lines examined and is probably sufficient for tumor maintenance. Oncogenesis could result from the insertion of T-DNA onto host genes crucial to the control of cell division or from the action of a specific oncogenic gene product, analogous to the tumor (T)-antigen of simian virus 40 (SV40)-transformed rodent cells. At least a part of T-DNA is transcribed in the plant cell. Hormone imbalance is also strongly implicated in the etiology of crown gall disease. Crown gall tumors can regain normal morphology under certain conditions, with the reversion taking place at the phenotypic or genotypic level. The author speculates that Ti plasmids may be used as factors to insert a chosen DNA sequence into the genome of any dicotyledonous plant. (79 refs)

- 79-6038 Models of Chemical Hepatocarcinogenesis and Oncodevelopmental Gene Expression. (Eng) Stillman, D. (Dept. Biology, Univ. California at San Diego, La Jolla, CA 92093); Sell, S. *Methods Cancer Res* 18: 135-168; 1979.

The production of oncodevelopmental gene products during exposure of the liver to carcinogens is reviewed. The products discussed include enzymes and isoenzymes, α -fetoprotein (AFP), nonhistone proteins, preneoplastic antigen, and isoferitins. Exposure to hepatocarcinogens leads to progressive morphologic changes in populations of adult liver cells, so that they eventually resemble fetal liver cells. Immunological and biochemical studies have provided evidence that genes that are active during fetal and neonatal development, yet essentially silent in the adult, may be activated during carcinogenesis. Chemical hepatocarcinogenesis involves a series of sequential changes in hepatocyte morphology accompanied by biochemical changes. Production of high levels of AFP, fetal isoenzymes, or other products may precede obvious morphological changes. However, although there is suggestive evidence, it has not been established whether sequential changes in gene expression, as indicated by AFP production and ultrastructural changes, are essential steps prior to malignant transformation. Similarly, although circumstantial evidence exists, there is no formal proof of an evolution of cancer from premalignant nodules or morphologically altered cells. Oncodevelopmental gene products are also expressed in transplantable hepatomas. Each hepatoma expresses a pattern of enzyme activities that is essentially unique for the given tumor. Fetal enzyme activities are commonly expressed, but the overall pattern for any given tumor is different from any given point in the development of the fetal liver. (125 refs)

- 79-6039 Oncodevelopmental Antigen Expression in Chemical Carcinogenesis. (Eng) Rees, R. C. (Cancer Res. Campaign Labs., Univ. Nottingham, Nottingham, England); Price, M. R.; Baldwin, R. W. *Methods Cancer Res* 18: 99-133; 1979.

The available information pertaining to fetal antigens in chemical carcinogenesis is reviewed, along with relevant information from studies using virally induced or spontaneously arising tumor systems. Topics discussed include phase-specific gene products of the fetus and fetal gene expression by adult cells; the expression and occurrence of oncodevelopmental antigens; the characteristics of oncodevelopmental antigens; and the immunogenicities of tumor-associated and oncodevelopmental antigens. (89 refs)

- 79-6040 Mechanisms of Carcinogenesis: Implications and Relevance to the Role of Nutrition in Cancer Causation. (Eng) Stewart, B. W. (Sch. Pathology, Univ. New South Wales, Box 1, Kensington, NSW 2033 Australia). *Nutr Cancer* 1(3): 46-51; 1979.

The role of nutrition in the etiology of cancer is reviewed. The vast majority of chemical carcinogens are metabolized by microsome-associated enzymes and there is a concomitant production of reactive intermediates able to bond covalently with the constituents of normal tissue. Available evidence suggests that binding of carcinogen adducts to DNA is of particular significance. The development of neoplasia is almost invariably associated with continual exposure to a carcinogen(s) and to some stimulus to cell proliferation. There are classes of carcinogens that may occur as dietary contaminants, and it has recently been established that some carcinogens may be formed in the digestive tract from non-carcinogenic components. The activity of enzymes responsible for the metabolism of carcinogens and similar exogenous compounds may be subject to extreme modulation by variations in diet. This dietary influence may be mediated through parameters ranging from the chemical and microbiological environment of the digestive tract to the activity of hepatic microsomal enzymes. Such factors may, in turn, determine the structure and quantity of carcinogenic intermediates to which tissues are exposed. (49 refs)

- 79-6041 Dietary Deficiency of Protein, Amino Acids and Total Calories on Development and Growth of Cancer. (Eng) Jose, D. (Clinical Immunology and Immunogenetics, Cancer Inst., 481 Little Lonsdale Street, Melbourne, 3000, Australia). *Nutr Cancer* 1(3): 58-63; 1979.

The effects of dietary deficiencies of protein, amino acids, and total calories on the development and growth of cancer are reviewed. The major source of information on this subject comes from studies of such deficiencies in experimental systems. Caloric restriction (one-half to one-third control intake) has influenced the genesis of virtually all mouse tumors studied, but only when the low-calorie diets were also low in fat. The extent of the inhibitory effects on tumorigenesis in these studies was related to the duration of the dietary restriction. Diets deficient in protein were associated with a 50% reduction in carcinogen-induced leukemia in DBA mice and a markedly reduced incidence of spontaneous mammary tumors in C3H mice. Selective deficiency of one essential amino acid in the diet inhibited tumor growth in numerous experiments; in most of the experiments in which this effect was measured, there was also a reduction in body wt on these diets. Diets deficient in tyrosine and phenylalanine were also associated

with reductions in metastatic disease and arrests of primary tumor growth in human patients. (46 refs)

- 79-6042 Food Additives. (Eng) Farrer, K. T. (Kraft Foods Limited, Box 1673N, G. P. O., Melbourne, Victoria, 3001, Australia). *Nutr Cancer* 1(3): 100-103; 1979.

Food additives are reviewed with regard to definition, reasons for their use, concentrations used, and control of their use. In Australia, food additives may be used only if specifically permitted to be added to the product in question and then only up to a given concentration. The max concentrations are derived from recommendations by the Joint Expert Committee on Food Additives of the Food and Agricultural Organization/World Health Organization. Acceptable daily intakes for all additives are derived from data on their biochemistry; carcinogenicity, mutagenicity, teratogenicity, etc; their acute, subacute, and chronic toxicity; observations in man; and studies on transformation products or impurities. The final question in the use of food additives is one of risk benefit. (18 refs)

- 79-6043 Introductory Remarks: Consideration of Experimental Thresholds. (Eng) Golberg, L. (Chemical Industry Inst. Toxicology, Research Triangle Park, NC). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 87-95; 1978.

Problems involved in the extrapolation of results from toxicological studies in animals to humans are considered. The organ damage observed at high doses may bear little or no relationship to whatever physiological perturbations may be induced by the same compound at doses to which humans are exposed. Where the traditional high-dose approach is used as part of a dose-response study, knowledge of metabolic pharmacokinetic properties of the test substance permits assessment of the metabolite load at the various doses and facilitates interpretation of the toxicological findings. The concept of relative risk should include an understanding of environmental carcinogens and mutagens present in natural foods. Endogenous factors such as the production of nitrosamines as well as of protective factors (eg, antioxidants) should be given special attention when assessing risk to humans from environmental agents. A balanced approach to statistical extrapolation not only has a place in interpreting likely low-exposure effects from the data obtained with high doses but can yield new insights into the biological process itself. (12 refs)

- 79-6044 Chemical Carcinogenesis in Syrian Hamsters: A Review (Through 1976). (Eng) Homburger, F. (Bio-Res. Inst., Cambridge, MA). *Prog Exp Tumor Res* 23: 100-179; 1979.

The recent literature concerning chemical carcinogenesis in the Syrian golden hamster is reviewed. Summaries and evaluations of published material are provided, along with abstracts, most of which were taken from published papers. Chemical carcinogenesis of the skin, subcutaneous tissue, cheek pouch, oral cavity, tongue, respiratory tract, gastrointestinal tract, liver and biliary tract, kidney, urinary bladder, prostate, ovary and thyroid, testicles,

mammary gland, pancreas, and adrenal is reviewed, as are the effects of inhaled chemical carcinogens. (199 refs)

- 79-6045 Introductory Remarks. (Eng) Munro, I. C. (Toxicology Res. Div., Bureau Chemical Safety, Health and Welfare Canada, Ottawa, Canada). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 165-167; 1978.

The concepts of thresholds and acceptable daily intakes as related to the safety of chemicals in food, drugs, and the environment are reviewed. A major problem facing toxicologists is whether thresholds exist for mutagenic and carcinogenic events in mammalian systems. It has been suggested that no safe dose exists for chemical carcinogens. Before thresholds can be established, the factors affecting them must be determined. The ability of endogenous compounds to trap electrophilic agents and prevent them from reaching their critical targets must also be investigated. With regard to toxic events that occur in low incidence and show wide intertrial variations, it is impossible to identify the biochemical events related to the toxic manifestations. (no refs)

- 79-6046 Environmental Chemicals Causing Cancer and Genetic Birth Defects: Mutagenicity Testing for Reactive Metabolites. (Eng) Ames, B. N. (Dept. Biochemistry, Univ. California, Berkeley, CA 94720). *Adv Pharmacol Ther* 9: 29-40; 1979.

Mutagenicity testing for the reactive metabolites of environmental chemicals causing cancer and genetic birth defects is reviewed. Damage to DNA appears to be the most likely cause of cancer and genetic birth defects. Because of the long tumor latency periods, it is difficult to identify the mutagens and carcinogens causing cancer in humans. Chemicals to which humans are exposed in appreciable amounts should be screened in animal tests, but these tests are expensive, they present statistical problems related to small sample sizes, and they are not usually suitable for identifying the active agent in a complex mixture. Using special strains of *Salmonella* in combination with homogenized mammalian liver tissue, carcinogens and mutagens can be identified by means of their mutagenicity. In a test of several carcinogens and noncarcinogens, 158/176 organic carcinogens were mutagenic and 95/108 noncarcinogens were nonmutagenic. The following chemicals identified by this test as mutagens were subsequently found to be human carcinogens: furylfuramide, ethylene dichloride, 1,2-dibromoethane, tris-(2,3-dibromopropyl)phosphate, and most common hair dyes. Since the development of the *Salmonella* test, there has been a resurgence of interest in other short-term mutagenicity tests. Because each of these tests detects a few carcinogens that the others do not, the concept of a battery of short-term tests is favored. A knowledge of carcinogenic potency, which can be gained by both animal cancer and short-term mutagenicity tests, is important for the assessment of human risk. (19 refs)

- 79-6047 DDT and Cancer. (Eng) Jukes, T. H. (Univ. California, Berkeley, CA 94704). *Clin Toxicol* 14(4): 461-463; 1979.

The claim that DDT exposure causes cancer is disputed. DDT feeding in rats for 2 yr (most of the rat lifespan) results in a minimal hepatocarcinogenic tendency. Liver changes identical to those produced by phenobarbital, pyrethrum, and other chemicals were seen 14 wk after DDT feeding in rats and could be produced in rabbits, mice and guinea pigs, but not in chickens, dogs, cats, and monkeys or large domestic animals. In another study, no tumors were found in three generations of dogs (>500 animals) raised on diets containing high DDT doses. Factory workers in DDT production and men who have been involved in spraying DDT for many years have shown no indication of DDT causing cancer. This is in marked contrast to other industrial carcinogens, including asbestos, arsenic, vinyl chloride, and dimethylchloroether. According to the World Health Organization, extensive medical tests of 150 persons with prolonged occupational exposure to large doses of DDT have not revealed any related findings except increased storage and excretion of DDT and its metabolites and mild stimulation of hepatic microsomal enzymes. (no refs)

- 79-6048 Short-Term Tests for Carcinogens and Mutagens. (Eng) Hollstein, M. (Dept. Biochemistry, Univ. California, Berkeley, CA 94720); McCann, J. *Mutat Res* 65(3): 133-226; 1979.

Short-term tests used to determine the potential mutagenicity and carcinogenicity of chemicals are reviewed. The major methods were placed into one of eight general categories: tests in prokaryotic microorganisms, phages, etc.; tests using eukaryotic microorganisms; mutagenesis tests in cultured mammalian cells; tests for DNA-repair effects and DNA-replication inhibition; in vitro transformation tests; in vivo tests in mammals; tests in insects; and in vitro and in vivo mammalian cytogenetics tests. Tests from each of these categories were used to analyze 72 carcinogens and mutagens. Many tests detected chemicals from a wide variety of different chemical classes, some chemicals being potent in one test system and weak in others. Qualitatively, results in one short-term test tended to reinforce results in other tests, and most carcinogens were positive in a number of short-term tests; exceptions included DDT, DDE, dieldrin, phenobarbital, and diethylstilbestrol. Results in the different tests were internally consistent in that each system tended to detect some classes of carcinogens more efficiently than others. The tests tended to complement one another in that carcinogens not detected by some tests were detected by others. The following essential components of a complete evaluation of short-term tests are discussed briefly: the relative effectiveness of short-term tests in identifying chemicals as "noncarcinogenic"; the predictive value of short-term tests; the relationship between potencies in these tests and potency in vivo; designing test batteries; and the role of short-term tests in cancer and genetic hazard policy. (678 refs)

- 79-6049 Risk Assessment of Ethylene Oxide and Other Compounds. (Eng) Ehrenberg, L. (Wallenberg Lab., Stockholm Univ., Stockholm, Sweden). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978*. McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 157-190; 1979.

The principles used for risk assessment of mutagenic and carcinogenic compounds are reviewed using ethylene oxide as a model compound. Quantitative analysis of existing data is needed to determine the resolving power of biological tests, to make quantitative risk assessments for man, and to determine whether a negative test excludes an unacceptable risk. Ionizing radiation is the only environmental factor that has been subjected to quantitative risk estimates. Three generalizations favor the application of the unit of radiation risk as a general unit of chemical risk (ie, establishing the "rad-equivalence" of a unit dose of a chemical): (1) the linearity at low doses of dose-response curves; (2) the finding that mutation frequency is determined by the number of alkylations of certain DNA centers; and (3) the finding that the number of such alkylations per unit amount of DNA that is associated with the same response as 1 rad of gamma radiation is the same in bacteria, plants, and mammals. Risk estimates for animals require knowledge of the in vivo dose associated with the uptake of a certain amount of compound, this dose being determined by the rates of absorption, chemical and metabolic reactions, distribution, transport, and excretion. Measurement of hemoglobin alkylation represents a method for identifying populations at risk and is applicable to primary and secondary mutagens and carcinogens. The same data may be used to quantify the risk using unit radiation risk as a standard. The demonstration of alkylation in vivo can be considered a sufficient criterion of genetic risk, and the demonstration of hemoglobin alkylation is a criterion of risk of heritable damage. (26 refs)

- 79-6050 Chloroprene (2-Chloro-1,3-butadiene)-- What Is the Evidence for Its Carcinogenicity? (Eng) Haley, T. J. (Dept. Health, Education, and Welfare, Food and Drug Admin., Natl. Center Toxicological Res., Jefferson, AR 72079). *Toxicol Annu* 3: 153-170; 1979.

The chemical, biological, and potentially carcinogenic activities of chloroprene are reviewed. Topics discussed include the synthesis and analysis of chloroprene, its biochemistry and metabolism, its toxicity for animals and humans, and its carcinogenicity. Sc injection of chloroprene into rats before or after transplantation of Crocker's murine sarcoma resulted in an acceleration of tumor growth. Chloroprene and its derivatives induced skin cancers in 137/24,989 Soviet workers. The neoplasms were found most often on the face, neck, nose, and hands, and they were associated with chronic dystrophic or inflammatory skin conditions. Lung cancer was also found in 87/19,979 chloroprene workers, 18 with direct and prolonged exposure to chloroprene and 16 with exposure to chloroprene latexes. (149 refs)

- 79-6051 Colon Cancer Epidemiology and Possible Causation. (Eng) MacLennan, R. (Sch. Public Health and Tropical Medicine, Building A27, Univ. Sydney, Sydney, New South Wales 2006, Australia). *Nutr Cancer* 1(3): 64-66; 1979.

The possible factors responsible for the development of colon cancer are reviewed. Colon cancer is among the most common cancers in most Western countries but occurs in a much lower incidence in most developing countries. Colon cancer rates for males and females are similar, whereas rectal cancer rates show variations with sex. Japanese migrants in Hawaii show rapid increases in colon cancer incidence within 20-30 yr of migration with shifts toward the American pattern. In general, populations in transition show increases in the diseases. Social class is also a risk factor, the incidence increasing with income. The distribution patterns for

colon cancer are consistent with the theory that diet is involved in its etiology. High correlations have been shown between colon cancer and meat and total fat consumption. There is indirect evidence for a negative association with dietary fiber. It has been suggested that bile acids are metabolized by intestinal bacteria to carcinogens or cocarcinogens that act on the colon and rectum. A high correlation was found between colon cancer mortality and the intestinal concentration of dihydroxycholesterol, a bacterial metabolite of bile acids. A recent study of colon cancer incidences in Scandinavia and New York suggested that colon cancer probably has a multifactorial etiology. (17 refs)

- 79-6052 Asbestos and Smoking (Letter to Editor). (Eng) Selikoff, I. J. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY); Hammond, E. C. *JAMA* 242(5): 458-459; 1979.

The association between smoking, asbestos, and cancer is reviewed. The two most common asbestos-induced cancers are lung cancer and mesothelioma. The former is usually related to cigarette smoking, whereas the latter is not. Similarly, cancers of the esophagus, larynx, and oropharynx occur in excess primarily in asbestos workers who have a history of cigarette smoking, whereas the incidences of colorectal and renal cancers are increased in such workers regardless of smoking history. While asbestos by itself somewhat increases the risk of cancer, smoking by itself causes a major increase. One in every five deaths among asbestos workers is due to lung cancer. Smoking, which causes bronchitis, emphysema, and fibrosis, adds an undesirable and sometimes insupportable burden to asbestos-induced pneumoconiosis. All workers known to have been exposed to asbestos should be advised never to smoke or to stop smoking as soon as possible. Periodic medical surveillance would further reduce the risk of gastrointestinal, oropharyngeal, laryngeal, and renal cancers, and therapy for superimposed pulmonary infections would limit the incidence of asbestosis. - 79-6053 Occupational Lung Cancer and Smoking: A Review in the Light of Current Theories of Carcinogenesis. (Eng) Chovil, A. C. (Industrial Medicine Consultant, Ontario Workmen's Compensation Board, 2 Bloor St. E., Toronto, Ontario M4W 3C3, Canada). *Can Med Assoc J* 121(5): 548-550, 553-555; 1979.

Modern theories of carcinogenesis are considered as they apply to the induction of lung cancer by tobacco smoking and occupational exposure to carcinogens. Some of the known and postulated factors affecting carcinogenesis are discussed, with particular reference to cocarcinogenesis and thresholds. Factors affecting the intensity of smoking exposure are reviewed; and the generally accepted occupational lung carcinogens are listed, including asbestos, arsenic, nickel, chromates, chloromethyl ethers, coal tar distillates, mustard gas, and ionizing radiation. Relative risks for the various carcinogens according to smoking status (where known) are presented. The carcinogens are considered individually, and known or postulated interactions with smoking are discussed. (54 refs)

- 79-6054 Carcinogenic Actions of Inorganic Constituents of Particulates Suspended in Air. (Ger) Brockhaus, A. (No affiliation given). *Lufthyg Silikoseforsch* 11: 99-106; 1978.

In order to evaluate the carcinogenic importance of various contaminants suspended in air, the evidence for carcinogenicity of several inorganic elements and compounds is reviewed. Results summarized by the International Agency for Research on Cancer indicate that, in addition to asbestos, nickel compounds, nickel-carbonyl, insoluble chromium compounds, and beryllium and Be compounds are also carcinogenic air pollutants. Five epidemiological studies show that the carcinogenic actions of asbestos and cigarette smoke are synergistic. There is also evidence that synergism exists between exposure to Ni compounds found in refineries and smoking. Although higher than expected cancer rates have been found in iron miners, the substances responsible have not been identified. A study of lung cancer incidence from 1950 to 1969 in the US revealed an above av incidence ($p < 0.05$) in 36 areas in which mining and refining of heavy metals, especially Cu, Pb, and Zn was done. Tobacco use was not investigated in this study. The results of these studies may suggest that suspected carcinogenic air pollutants interact and may act synergistically; for this reason, future epidemiological and animal studies should concentrate on the effects of various combinations of air pollutants. (20 refs)

- 79-6055 Carcinogenic Properties of Vulvovaginal Preparations (Letter to Editor). (Eng) Venter, P. F. (Dept. Obstetrics and Gynecology, Univ. Orange Free State, Bloemfontein, South Africa). *S Afr Med J* 56(16): 625; 1979.

The possible carcinogenic properties of vulvovaginal preparations are discussed. Some chemicals used in vaginal preparations that have been implicated in carcinogenesis are arsenic, 8-hydroxyquinoline, nitrofur, ichthammol, sulfonamides, metronidazole, certain spermicides, talc, asbestos, and gentian violet. The possible formation of carcinogenic nitrosamines; the possibility that chemical substances deposited in the vagina could migrate to the peritoneal cavity; and the fact that the uterus, fallopian tubes, ovaries, and peritoneal cavity are in direct contact with substances that may be present in the more external genital structures should be considered. (4 refs)

- 79-6056 Novel Activation Mechanism for the Promutagenic Herbicide Diallyl. (Eng) Schuphan, I. (Pesticide Chemistry and Toxicology Lab., Dept. Entomological Sciences, Univ. California, Berkeley, CA 94720); Rosen, J. D.; Casida, J. E. *Science* 205(4410): 1013-1015; 1979.

Diallyl (S-2,3-dichloroallyl diisopropylthiocarbamate) and triallyl sulfoxide were prepared and their degradation chemistry examined. *cis*-Diallyl sulfoxide underwent a rapid and quantitative conversion to 2-chloroacrolein and the carbamoylsulfonyl chloride. The *trans* isomer gave the same compounds but more slowly. Triallyl sulfoxide degraded to 2-chloroacrylyl chloride. The products originate from a [2,3] sigmatropic rearrangement to a S-O-allylsulfenyl ester followed immediately by a 1,2-elimination reaction. Liver microsomes extensively metabolized the diallyl isomers but only in the presence of NADPH. Rats given carbonyl- ^{14}C -labeled diallyl po expired 20% $^{14}\text{CO}_2$ and their urine contained 62% mercapturic acid conjugate and 9% other metabolites originating from the carbamoyl-glutathione (GSH) derivative. Dichloroallylsulfonic acid was the major metabolite of (allyl- ^{14}C)diallyl in mice and rats and their microsomal-NADPH systems. These results indicate that under biological conditions, diallyl sulfoxide undergoes either the major detoxifying GSH conjugation or the minor, competing [2,3] sigmatropic rearrange-

ment reaction followed by 1,2-elimination to liberate a toxicologically significant metabolite, most probably 2-chloroacrolein. Triallate sulfoxide is unstable and is probably the proximate mutagen. (14 refs)

- 79-6057 Formation of Carcinogenic N-Nitroso Compounds in the Living Organisms and in the Environment. (Hun) Borzsonyi, M. (Országos Kozegeszsegügyi Intezet, Budapest, Hungary); Pinter, A. *Magy Onkol* 23(3): 171-179; 1979.

Studies on the formation of carcinogenic N-nitroso compounds in vivo and in the environment are reviewed. The formation of N-nitroso compounds from precursors is enhanced by certain bacteria, eg, *Staphylococcus aureus*, by thiocyanate present in human saliva; by SO_4 , Cl, Br, I, and PO_4 ions; and by complexes of Mo, Fe, Cu, Hg, and Co. The most important precursors of N-nitroso compounds include ephedrin, ethambutol, folic acid, morpholine, phemetrazine, piperazine adipate, dulcin, aminopyrine, Analgin, chlorpromazine, dextropropoxyphene, oxytetracycline, pyribenzamine, quinacrine, disulfiram, nicotine, nornicotine, hydroxypyrrolidine, proline, pyrrolidine, methylguanine, agmatin, trimethylaminoxide, trimethylamine, sarcosine, spermidine, spermine, as well as the active ingredients of some pesticides, such as carbaryl, propoxur, Hopcide, Baygon, Carbofuran, Benlate, Carbendazim, Dodin, benzthiazurone, Fenuron, Ferbam, Thiram, Ziram, semicarbazide, Alar, atrazine, simazine, and Triforin. The carcinogenic substances formed by the nitrosation include N-ephedrin, N-ethambutol, N-folic acid, N-morpholine, N-phenmetrazine, dinitrosopiperazine, dimethylnitrosamine, nitrosoanabasine, nitrosohydroxypyrrolidine, nitrosoproline, nitrosopyrrolidine, N-nitrososarcosine, 3-butenyl derivatives, N-nitrosocarbaryl, N-nitrosopropoxur, N-nitrosocarbofuran, methylnitrosourea, diethylnitrosamine, N-nitrosotriazine, and 1,4-dinitrosopiperazine. (71 refs)

- 79-6058 Problems of Dose-Response Studies in Chemical Carcinogenesis with Special Reference to N-Nitroso Compounds. (Eng) Schmahl, D. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Heidelberg, W. Germany). *CRC Crit Rev Toxicol* 6(3): 257-281; 1979.

The benefits and limits of dose-response experiments in chemical carcinogenesis are reviewed. Dose-response experiments can give information concerning the potency of a carcinogen, its mode of action, its threshold (risk assessment), and its effect in combination experiments if they are performed with an appropriate experimental design. Variables which must be considered in the design of dose-response experiments include the animal species and strain, dose range, mode and frequency of application, and length of observation period. Extrapolations of experimental results to other strains or species can only be made speculatively and with reservations. In estimating the carcinogenicity of N-nitroso compounds for man from data obtained in animal experiments, relatively firm conclusions can be drawn because the compounds have been tested in a variety of animal species and have proved to be more or less equally carcinogenic. This applies to both the dose which is required for tumor induction and the organotropism of the effect. The N-nitroso compounds can cause malignant tumors in practically all parenchymatous organs after systemic application, except in the ovaries, testicles, uterus, and adrenal gland. Repeated single applications of carcinogen are more effective than one application of a high dose. The effect obtained with one partial dose is irreversible and remains capable of

summation. It is concluded that the greatest practical importance of dose-response studies is the determination of tolerance limits for environmental chemicals. (103 refs)

- 79-6059 Biological N-Methylation and Demethylation and Pathological Cell Proliferation. (Hun) Tyihak, E. (Gyogynoveny Kutato Intezet, Budakalasz, Hungary). *Magy Kem Lapja* 34(4/5): 190-198; 1979.

Recent studies on possible relationships between biological N-methylation, N-demethylation, and malignant cell proliferation are reviewed. There is an evident correlation between hypermethylation in the human body and malignant cell proliferation. The hypermethylation may be a consequence of increased enzymatic transmethylation or spontaneous chemical methylation. In the latter reaction formaldehyde is the foremost agent suspected of being formed either from nitrosamines or as a result of increased demethylase activity in the presence of aromatic hydrocarbons or viruses in different tissues. Increased levels of methylated nucleic bases have been found in the urine of cancer patients compared with healthy controls. Ne, Ne, Ne -trimethyl-L-lysine has been found to have a considerable tumor growth-enhancing effect in mice with NK/LY ascitic tumors; the number of tumor cells and the percentage of the cells in mitosis were increased after administration of single or multiple 5-10 mg/kg doses. (61 refs)

- 79-6060 Are Nitrites and Sweeteners Carcinogenic? (Swe) Werko, L. (Astra AB, Sweden). *Lakartidningen* 76(30/31): 2607-2608; 1979.

The debates and controversies around saccharin and nitrite as food additives in the US are discussed. Saccharin was found to be carcinogenic when administered to laboratory animals in very high doses, and nitrites have a tumor promoting rather than a carcinogenic effect. (5 refs)

- 79-6061 Comparison of Studies on Saccharin and Sodium Nitrite. (Eng) Taylor, J. M. (Div. Toxicology, Food and Drug Admin., Washington, DC 20204); Morgenroth, V. H. *J Assoc Off Anal Chem* 62(4): 883-888; 1979.

A review of long-term animal studies of saccharin and sodium nitrite was undertaken to assess the effect of variations in selected elements of protocol on the results obtained. These elements were divided into four general categories: design, including selection of test animals, basal diet, dosage form and doses of test substance, route of administration, and duration of exposure; observations, including gross observations during life and at necropsy, clinical tests, and histopathology; performance, including conduct of the test and animal husbandry; and analytical procedures, including chemical and statistical methods. Because many of these elements were not fully discussed in the study reports, it was often impossible to determine what actually had been done. The review of various saccharin studies suggested that bladder tumors resulted following in utero exposure, whereas in utero exposure to sodium nitrite did not appear to cause reticuloendothelial changes. The numerous variations in protocol in the nitrite studies precluded identification of a prime element responsible for the variations in reticuloendothelial changes observed. It can be concluded that achievement of reproducibility in long-term studies requires minimal variations in protocol for new studies. (11 refs)

- 79-6062 Carcinogenicity of Cosmetic Materials. (Eng) Prunieras, M. (Lab. Human Skin Tumors [INSERM FRA 14], Fondation Adolphe de Rothschild, 29 rue Manin, 75019 Paris, France). *Adv Pharmacol Ther* 9: 277-287; 1979.

The carcinogenicity of cosmetic materials is reviewed. Preliminary data have indicated that at least nine ingredients used in the dyes are carcinogenic when fed to rats and mice, and two semipermanent hair dyes have been shown to be carcinogenic for mice following topical application. Various regulations exist concerning the amounts of carcinogenic polycyclic hydrocarbons which may be incorporated into mineral oils, which are used in large quantities in cosmetics. Skin care products, cosmetics, beauty aids, and hair shampoos also may contain variable amounts of N-nitrosodiethanolamine, a compound which was proven carcinogenic in rats. A wide variety of materials commonly used in cosmetic creams, milks, and other products have been shown to induce acanthosis in guinea pig skin; these include paraffin oil, petrolatum jelly, castor oil, lauric and oleic acids, and fatty acids. A basis for dealing with known or suspected occupational carcinogens has been provided by the American Occupational Safety and Health Administration, but clearance of cosmetic products by public health services prior to marketing is not mandatory in any country. It is important to understand that if some cosmetic material includes chemical ingredients with carcinogenic potential, this potential is very weak. (33 refs)

- 79-6063 Factors Influencing DNA Damage and Its Repair with Cellular Implications for Toxicology. (Eng) Sarma, D. S. (Dept. Pathology, Univ. Toronto, Medical Sciences Bldg., Ontario M5S 1A8, Canada); Rajalakshmi, S.; Udupa, R. S.; Farber, E.; Rao, P. M. *Adv Pharmacol Ther* 9: 71-79; 1979.

Factors influencing DNA damage and repair are reviewed, and the cellular implications for toxicology are discussed. Carcinogens can, either directly or after suitable metabolic activation, interact with both the purines and pyrimidines in DNA and, in some cases, with the phosphate as well. In addition to the pure chemical factors that influence the sites of interaction of carcinogens with DNA, the availability of these sites in chromatin DNA is determined by the several hierarchies of organization of the DNA in chromatin. Carcinogens exhibit preferential interactions with some regions of the DNA (eg, dimethylnitrosamine methylates predominantly the DNase I-digestible regions of chromatin DNA). The availability of the DNA in chromatin to repair enzymes is also subject to restrictions imposed by the hierarchy of the folding of DNA in the nucleus. Although the precise role of cell proliferation in cellular damage is not fully understood, the available data are compatible with the hypothesis that the replication of DNA with unrepaired damage helps fix the damage in the daughter strand, a step that may be obligatory in the toxicologic, mutagenic, and carcinogenic processes in the cell. (45 refs)

- 79-6064 New Aspects of Nitrosamine-induced Carcinogenesis. (Eng) Magee, P. N. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Adv Pharmacol Ther* 9: 81-91; 1979.

The metabolism and organ specificity of the N-nitroso compounds are reviewed. Nitrosamines and other N-nitroso compounds are effective carcinogens, inducing tumors in most organs in a wide range of species. These compounds are also powerfully mutagenic, and several have been shown to alkylate DNA and other cellular

macromolecules in different organs. In the case of dimethylnitrosamine, the metabolic pathway leading to the alkylating intermediate is quantitatively the major one. The organ specificity or organotropism of the N-nitroso compounds may be dependent on the capacity of the organs to activate them, when necessary, and on the variable persistence of certain alkylated components of DNA. Other, as yet unidentified, factors are probably also involved. (74 refs)

- 79-6065 The Role of DNA Alkylation and Repair in the Toxic and Carcinogenic Effects of Alkyl Nitrosoureas. (Eng) Kleihues, P. (Pathologisches Institut der Universität Freiburg, Freiburg, W. Germany). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 191-205; 1978.

The formation of DNA lesions and their persistence in various organs in vivo are reviewed. Monofunctional alkylating carcinogens react at all available nucleophilic sites in DNA bases. Compounds that react predominantly at nitrogen atoms in DNA bases are generally weak carcinogens, whereas agents which lead preferentially to O-alkylation are usually strong carcinogens. Some alkylated bases are removed from DNA by chemical depurination, others by enzymatic excision, and some by both mechanisms. The loss of alkylated bases leads to the formation of apurinic sites that contribute to the cytostatic and lethal effects of alkylating agents. In rats, the location of neural and renal neoplasms seems to be related to a deficiency of the target tissues in excising O⁶-alkylguanine from their DNA. This correlation is less consistent in mice; additional genetically determined factors may modify tumor development following promutagenic changes in DNA. The excision repair system for O⁶-methylguanine in rat liver can be inhibited in a dose-dependent manner with sublethal doses of methyl nitrosourea and related carcinogens. A similar dose-dependent inhibition of the rate of excision does not seem to exist in the brain. It is concluded that the data on the interaction of neuro-oncogenic agents with DNA support the hypothesis that the induction of tumors is initiated by a change in gene structure rather than in gene function. (55 refs)

- 79-6066 Critical Review of the Toxicology of Coumarin with Special Reference to Interspecies Differences in Metabolism and Hepatotoxic Response and Their Significance to Man. (Eng) Cohen, A. J. (Toxicology Advisory Services, 25, Cedar Road, Sutton, Surrey, England). *Food Cosmet Toxicol* 17(3): 277-289; 1979.

The validity of studies indicating that rats fed coumarin at 5,000 or 6,000 ppm for 2 yr develop bile duct carcinomas has been questioned, in view of the absence of significant metastasis and of negative findings in an earlier carcinogenicity study. Coumarin does not act as a cocarcinogen in mouse skin and was not found to be carcinogenic following sc administration in rats in a limited study. Rats metabolize coumarin differently than do humans, which makes the use of this species for predicting the hepatotoxic risk in humans questionable. Because metabolism appears to be an important factor in determining the hepatotoxic response, species differences should be considered when evaluating the hepatotoxic hazard to humans. (58 refs)

- 79-6067 DNA Repair. (Eng) Setlow, R. (Biology Dept., Brookhaven Natl. Lab., Brookhaven, NY). In: *Bran-*

bury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978. McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 81-95; 1979.

DNA repair in bacterial and mammalian systems is reviewed. Excision repair has been categorized into two types: long patch, in which a region of DNA on the order of 100 nucleotides is removed and replaced; and short patch, which involves replacement of 1-10 nucleotides. The former is caused by UV and other bulky types of damage, and the latter occurs in cells exposed to x-rays or some alkylating agents. A third type of excision repair, zero patch, involves the replacement of zero nucleotides and has been documented for the 0-6 alkyl guanine following alkylation damage. Individuals with xeroderma pigmentosum (XP) are deficient in DNA repair; their cells are highly subject to mutation in culture; and they show a high incidence of skin cancer, especially malignant melanoma. XP cells in culture are sensitive to UV and many other agents. Individuals with ataxia telangiectasia (AT) show a fivefold increased cancer risk compared with the general population and are approx five times more sensitive to x-rays; their cells are sensitive to x-rays and alkylating agents in culture. The molecular nature of the defect in AT is unknown. Individuals with Fanconi's anemia, which involves a deficiency in the repair of cross-links, are also at increased risk of cancer, particularly leukemia. These data are discussed by a panel. (22 refs)

79-6068 Estimating Radiation-induced Genetic Disease Burdens. (Eng) Abrahamson, S. (Dept. Zoology, Univ. Wisconsin, Madison, WI). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978.* McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 147-156; 1979.

The methodology employed by the BEIR committee in developing risk estimates for the genetic effects of radiation is reviewed. The committee employed a relative-mutation-risk procedure using a value that is the inverse of the amount of radiation required to double the current incidence of mutationally maintained disease in a continuously exposed population. The methodology is discussed by a panel. (4 refs)

79-6069 Genetic Damage from Diagnostic Radiation? A Critique of the Bross and Natarajan Study. (Eng) Oppenheim, B. E. (Dept. Radiology, Indiana Univ. Sch. Medicine, 1100 W. Michigan St., Indianapolis, IN 46223). *JAMA* 242(13): 1390-1393; 1979.

A critique of a previous analysis of the effect of intrauterine exposure to diagnostic radiation is presented. In the original article, it was hypothesized that low-dose fetal irradiation in the 0.5-5.0 rad range confines its damage to 1% of exposed subjects and that for this affected group there is a 5,000% increase in the risk of leukemia compared with that in unexposed subjects. According to the present author, the radiation doses are grossly misrepresented. At most one-third of the irradiated subjects in the previous study were exposed directly to the x-ray beam (giving an exposure in the 1-rad range), as occurs when the mother receives an abdominal x-ray; the remaining subjects were exposed to a dose of about 0.001

rad, as their mothers received only a chest x-ray. In the original article, the proportion of subjects aged 1 to 4 whose mothers received x-rays during pregnancy was reported to be 0.289. This value is appropriate for the exposed fraction of nonleukemic subjects, but a value of 0.379 should have been used for the exposed fraction of leukemic subjects. Inappropriate sampling techniques were used to select members of the unexposed group because children with postnatal x-rays were excluded from the unexposed group. It is concluded that the original article produced no evidence that the radiation hazard is any greater than that indicated by previous investigators. (18 refs)

79-6070 Radiation-induced Cancer. (Eng) Baum, J. W. (Safety and Environmental Protection Div., Brookhaven Natl. Lab., Upton, NY 11973). In: *Branbury Report. 1. Assessing Chemical Mutagens: The Risk to Humans. Proceedings of a Meeting sponsored by the Office of Toxic Substances, U. S. Environmental Protection Agency, held in Lloyd Harbor, NY, May 1978.* McElheny, V. K.; Abrahamson, S., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): 367 pp.; 117-134; 1979.

Animal and human data on radiation carcinogenesis and mathematical models that may relate to mutagenesis and carcinogenesis are reviewed. Tissues that are relatively resistant to radiation-induced cancer tend to show sigmoid dose-effect relations, and the more densely ionizing radiations (eg, alpha particles) are usually more effective than x- or gamma-rays in inducing tumors. More sensitive tissues may respond at even very low doses, and the slope of the dose-response curve at low doses may be nearly linear. The effect of chronic exposure to x- or gamma-rays is often less than that of acute exposure. The thyroid is a moderately sensitive organ; the dose response for it may be linear at very low doses after which it peaks and then comes down. Mammary tumors are seen very early in irradiated rats, and when the dose is higher the incidence increases. Thus, both promotion and induction occur. A model is proposed in which carcinogenic events are assumed to occur naturally at a constant rate and that there are six different classes of cells that appear progressively as the events occur. The results of one experiment suggested that radiation-induced steps occur two at a time. Population heterogeneity in human epidemiological studies can drive dose-response curves toward a power function less than the inherent underlying power functions of the various subpopulations. For all malignancies among survivors of the Hiroshima bombing and for Japanese women with breast cancer, the dose response was about a one-half power function in early analyses, but, according to the multiple-event model, it would be expected to be linear when the populations have completed their life spans. Children in human studies have proven to be slightly more sensitive than adults. Radiation protection standards must consider the risk vs the cost of reducing that risk. (18 refs)

79-6071 Skin Cancer After PUVA Treatment for Psoriasis (3 Letters to Editor). (Eng) Morgan, R. W. (Univ. Toronto, Toronto, Ontario M5S 1A8, Canada); Spellman, C. W.; Stern, R. S.; Thibodeau, L. A.; Parrish, J. A.; Fitzpatrick, T. B. *N Engl J Med* 301(10): 554-555; 1979.

Three letters concerning an article on skin cancer following PUVA (methoxypsoralen plus A-range UV light) treatment for psoriasis are presented. The results of studies in mice with topical 8-methoxypsoralen (8-MOP) and subcarcinogenic levels of B-range UV light suggest that failure to reject a transplanted tumor and

development of a tumor in a treated host may result from previous induction of specific suppressor cells. These phenomena may also occur in patients treated with PUVA. The absence of an adequate control group is discussed in two letters. The authors of the original article contend that valid observations can be made that suggest an increased risk of cutaneous carcinoma in a subset of patients treated with PUVA, even in the absence of a rigorous control group. (8 refs)

- 79-6072 Cancer and Slow Virus Diseases--Some Common Features. (Eng) Gross, L. (Veterans Admin. Medical Center, Bronx, NY 10468). *N Engl J Med* 301(8): 432-434; 1979.

Some features common to cancer and slow virus diseases are reviewed. Most malignant tumors, leukemias, and lymphomas in animals are caused by transmissible oncogenic viruses, and it is reasonable to assume that neoplastic diseases in man can also be caused by viruses. Several chronic degenerative diseases of the CNS are caused by transmissible viruslike agents: presenile dementia, scrapie (in sheep), and kuru. The diseases appear after very long latency periods and frequently last for several years or even decades. They are slow, progressive, and always fatal. Pathologic changes are essentially limited to the brain and are characterized by widespread vacuolar neuronal, spongiform degeneration and gliosis of the gray matter. Presenile dementia can be transmitted through corneal transplantation, brain surgery, or ingestion of contaminated food. The scrapie, kuru, and presenile dementia viruses readily cross species following experimental inoculation. Although oncogenic viruses are different from the viruslike agents that cause slow virus diseases, both groups of viruses are usually transmitted from one generation to another, and both groups have the ability to evade the immunologic responses in their hosts. (13 refs)

- 79-6073 The Scientific Heritage of Professor Zilber and his Contribution to Virus-Genetic Theory of Malignant Tumors. (Eng) Shevlyaghin, V. Y. (N. F. Gamaleya Inst. Epidemiology and Microbiology, AMS USSR, Moscow, USSR). *Neoplasma* 26(2): 113-123; 1979.

The scientific heritage of Professor Zilber, who first proposed the virus-genetic theory of malignant tumors, and his contribution to this theory are reviewed. Zilber's original hypothesis was that the etiological factor in tumors induced by physical and chemical agents is a tumor virus. Zilber's theory that the tumor virus is integrated into the genome of the cell was confirmed after Zilber's death. (131 refs)

- 79-6074 Inheritance and Expression of Chicken Genes That Are Related to Avian Leukosis Sarcoma Virus Genes. (Eng) Robinson, H. L. (Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545). *Curr Top Microbiol Immunol* 83: 1-36; 1978.

The inheritance and expression of chicken genes that code for avian leukosis sarcoma virus (ALSV) or viral products are reviewed. Topics covered include phenotypes for the expression of endogenous ALSV, expression of endogenous viral genes, inheritance of endogenous ALSV expression, and the immune response of chickens to endogenous viral antigens. No direct relationship between the expression of endogenous ALSV and the oc-

currence of cancer has been observed in chickens. Some viruses that cause neoplasia in chickens contain genes closely related to those of an endogenous ALSV, RAV-0. Some of these oncogenic ALSVs have additional genes not found in RAV-0, eg, sarcoma, myeloblastosis, erythroblastosis, myelocytomatosis, and carcinoma viruses. It is possible that the oncogenic Rous sarcoma virus (RSV) may have arisen from the recombination of RAV-0 or RAV-0-like viruses with *sarc*, a highly conserved cellular gene present in the microchromosomes of chicken cells. Other oncogenic ALSVs contain only those genes found in RAV-0 but have *env* genes that have diverged from RAV-0, these viruses cause leukosis, a disease that results in the appearance of metastatic B cells in the liver and spleen. It is speculated that the envelope antigens of the RAV-0 virus may not initiate the same immune response as the envelope antigens of oncogenic ALSV. It is also possible that the envelope antigens of the oncogenic viruses alter normal host controls over B cell growth so that metastatic disease appears. (186 refs)

- 79-6075 Permanent Teratocarcinoma-derived Cell Lines Stabilized by SV40 Transformation. (Eng) Levine, A. J. (Dept. Biochemical Sciences, Princeton Univ., Princeton, NJ 08540). In: *Oncodevelopmental Antigens*. Fishman, W. H., Busch, H., eds. (New York: Academic Press): Methods in Cancer Research Vol. 18, 409 pp.; 333-357; 1979.

The literature on permanent teratocarcinoma-derived cell lines stabilized by simian virus 40 (SV40) transformation is reviewed. SV40 infection is clearly required for establishment of the teratoma-derived cell lines (SVTER), and all the SVTER cell lines are only minimal transformants with respect to their growth potential in culture. The teratocarcinoma-derived cells appear to exert a strong influence over the SV40 genome and tumor antigen, so that these cells and cell lines retain a more normal phenotype in vitro and in vivo. The growth properties of embryonal carcinoma cells resembled those of fully transformed and tumorigenic SV40-transformed cell lines. The SVTER lines contained a number of other properties demonstrating that they are differentiated from embryonal carcinoma cells, and the teratocarcinoma-derived cells have distinct patterns of differentiation and sets of gene expression. It is possible, however, that the SVTER cell lines represent aberrant examples of developmental pathways. (68 refs)

- 79-6076 Viral Origin of Antigenic Markers in Simian Papovavirus SV40 Transformed Cells. (Eng) Tevethia, S. S. (Dept. Microbiology, Pennsylvania State Univ. Coll. Medicine, Hershey, PA 17033); Greenfield, R.; Pretell, J.; Tevethia, M. J. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, E. W., ed. (New York: Elsevier): 590 pp.; 67-72; 1978.

The early region of simian papovavirus 40 (SV40) DNA codes for two proteins: a 90,000- to 100,000-dalton (90K-100K) protein and a 17K protein. Both of these early gene products are precipitated by sera from animals bearing SV40-induced tumors [anti-tumor (anti-T) sera] and are therefore designated as T antigens. The same region also specifies transplantation-rejection antigen (TrAg) at the surface of SV40-infected or SV40-transformed cells and is involved in tumor rejection. Genetic and immunological evidence suggests that the antigenic sites for T and TrAg may be located on the same protein but that they are distinct. (25 refs)

- 79-6077 The Moloney Leukemia Virus-determined Cell Surface Antigen: Separation from Cell Membrane-associated Virion Proteins. (Eng) Fenyo, E. M. (Dept. Tumor Biology, Karolinska Inst., Stockholm, Sweden). In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, E. W., ed. (New York; Elsevier): 590 pp.; 47-51; 1978.

Current knowledge concerning a cell-surface antigen associated with Moloney murine leukemia virus (M-MuLV) infection of mouse cells is reviewed. The M-MuLV-determined cell-surface antigen has been separated from H-2 and virion proteins associated with the cell membrane by Sephadex G-200 chromatography and sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Multiple mol wt species possessing antigenic determinants for Moloney cell-surface antigen (MCSA) have been detected. Antibody-induced capping of gp71 and p15E did not affect the cell-surface distribution of MCSA, indicating that MCSA is a distinct entity. In contrast, MCSA cocapped with p30 and p12 virion protein antigens. This suggests that MCSA is linked to *gag* proteins on the lymphoma cell surface. (19 refs)

- 79-6078 The Role of Viral Transformation and Cytogenetic Changes in Viral Oncogenesis. (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Institutet, Stockholm, Sweden). *Ciba Found Symp* (66): 335-358; 1979.

The interaction of Epstein-Barr virus (EBV) with the human B lymphocyte, particularly as it relates to Burkitt's lymphoma (BL), is reviewed. In vitro EBV-transformed lymphoblastoid cell lines are initially purely diploid, do not grow in nude mice, and do not plate in agarose. BL biopsies and derived lines are not purely diploid, are regularly tumorigenic in nude mice, and grow in agarose. This implies that in vitro immortalization cannot be equated with in vivo tumorigenicity. For malignant growth in vivo, additional changes at the cytogenetic level appear to be required. Ninety-seven percent of the African BL examined are EBV-DNA- and EB nuclear antigen (EBNA)-positive. Only 22% of non-African BL cases carry the viral genome. About 90% of in vivo BL tumors studied were found to contain the same 14q+ marker. This marker has also been found in EBV-negative BL. Studies of the pathogenesis of BL suggest that it proceeds in three steps: (1) primary EBV infection in a young child, which immortalizes some B lymphocytes in vivo; (2) chronic stimulation of the proliferation of EBV-carrying preneoplastic cells by an environmental promoting agent (possibly malaria); and (3) chance appearance of chromosomally abnormal variants in the stimulated tissue; after certain types of chromosomal changes, particularly those leading to the 14q+ marker, the affected B lymphocyte no longer responds to negative feedback and proliferates. X-ray-, dimethylbenzanthracene-, and virus-induced experimental murine T lymphomas all show the same chromosomal change: trisomy 15. The fact that the same chromosomal anomaly is found in the ultimate tumor regardless of the initiating agent, suggests that the cytogenetic change, rather than the viral transformation, is the essential factor in oncogenesis. (22 refs)

- 79-6079 Tumor-associated Viruses of the Syrian Hamster: Relation to Neoplasia. (Eng) McCormick, K. J. (St. Joseph Hosp. Cancer Res., Stehlin Foundation Cancer Res., Houston, TX 77002); Trentin, J. J. *Prog Exp Tumor Res* 23: 13-55; 1979.

The tumor-associated indigenous hamster viruses and their possible role in neoplastic growth in this species are reviewed. The discussion is limited to the hamster papovavirus, the R-type particle, the intracytoplasmic A-type particle, and the C-type virion. The evidence indicates that the papovavirus and certain C-type virions are infectious and that, in the case of certain tumors, they are related to the neoplastic processes of the host. However, the importance of the type R and intracytoplasmic A-type virus like particles (VLP) in the induction of tumors in the hamster is not clear. Although activation or enhancement of certain viruses or VLP appears to occur through alterations in cellular metabolism via chemical or viral treatments, the mechanisms of activation and the probable concomitant interactions with the immune system of the host are completely unknown. (191 refs)

- 79-6080 The Hepatitis B Virus and Its DNA Polymerase: The Prototype Three-D Virus. (Eng) Hirschman, S. Z. (Div. Infectious Diseases, Mount Sinai Sch. Medicine, New York, NY 10029). *Mol Cell Biochem* 26(1): 47-67; 1979.

Studies concerning hepatitis B virus (HBV) are reviewed. The present concept of HBV is that of a small DNA-containing virus comprised of a 27-nm core with an outer coat of protein to produce a complete virion with a diameter of 42 nm. The core contains circular DNA comprised of 60% double-stranded and 40% single-stranded DNA. The core also contains a unique DNA-dependent DNA polymerase, which fills in the single-stranded gaps that may be in any part of the one strand of the DNA molecule facing the 3'-end of that strand. The surface protein of HBV, hepatitis B surface antigen (HBsAg), contains both lipid ($\leq 30\%$) and carbohydrate (3.6%-6.5%). HBsAg is often detected in particulate form in the blood of infected patients. Several serological techniques have been used, but radioimmunoassay is the most sensitive. There are four major primary subtypes of HBsAg; these appear to be coded by HBV and show different geographic distributions. Hepatitis B core antigen (HBcAg) is detected in the nuclei of infected human hepatocytes and appears to be of simpler chemical composition than HBsAg. In areas where HBV is highly endemic and infection is contracted at a very early age, there appears to be a relationship between HBV infection, cirrhosis, and primary hepatocellular carcinoma. HBsAg is variably found in the tumor cells that have been examined. A virus similar to human HBV has been found recently in woodchucks. (200 refs)

- 79-6081 Embryonic and Fetal Determinants on Virally and Chemically Induced Tumors. (Eng) Coggin, J. H. (Dept. Microbiology and Immunology, Coll. Medicine, Univ. South Alabama, Mobile, AL 36688); Ambrose, K. R. In: *Oncodevelopmental Antigens*. Fishman, W. H., Busch, H., eds. (New York: Academic Press): Methods in Cancer Research Vol. 18, 409 pp.; 371-389; 1979.

The literature concerning tumor-associated cell surface antigens; membrane, tumor-specific, or tumor-associated transplantation antigens; and intracellular antigens located in the nucleus (T antigens) is reviewed with respect to their detection, their role in the primary oncogenic event, and their roles in tumor elimination or progression as they interact with the immune system of the host. Cytostatic immunoglobulin was found in hamsters prior to the frank appearance of sarcoma as a palpable mass and in animals specifically rendered immune to simian virus 40 (SV40) tumor by immunization with irradiated cells or following successful surgical excision. A similar immunoglobulin appeared transiently in the

serum or peritoneal fluid of hamsters during normal pregnancies. Immunity generated by immunization with irradiated fetal cells was effective in preventing SV40 tumor production following live tumor cell challenge and conferred immunity to adenovirus-induced hamster tumors and polyoma-induced hamster tumor cell challenge. Irradiated fetal cells could be used as an immunogen to prevent the induction of primary tumors in hamsters infected at birth with SV40 or adenovirus 31. Consistent transplantation immunity was not detected when the embryo tissues were not irradiated prior to injection. However, irradiation did not appear to activate transplantation antigens. Fetal preparations from multiparous females were generally ineffective as immunogens, and the fetal antigen that could be detected on 9- to 10-day fetuses was not detectable on 11- to 15-day fetuses. The antigenic determinant on hamster fetus was also expressed on mouse and human embryos during the midgestation period. Every major viral or chemically induced tumor system of the rat, mouse, hamster, and guinea pig contains fetal antigens that can produce tumor transplantation resistance when irradiated midgestation fetuses from primiparous donors are used as an immunogen. A clear cross-protection was observed between animals immunized with irradiated SV40 tumor cells and challenged with adenovirus tumor cells and vice versa. (13 refs)

79-6082 Genetic Regulation of Immune Response to TNP-modified Cells. (Eng) Shearer, G. M. (Immunology Branch, NCI, Bethesda, MD 20014); Schmitt-Verhulst, A. M.; Pettinelli, C. B.; Shaw, S. *Gann Monogr Cancer Res* 23: 213-221; 1979.

Parameters characteristic of T-cell-mediated cytotoxic responses against trinitrophenyl (TNP)-modified murine and human cells generated in vitro are reviewed. The specificity of the effector cells generated in such cytotoxic responses is such that optimal lysis is detected when the responding, stimulating, and target cells share H-2K and/or H-2D haplotypes; the stimulating and target cells must both be modified by the same agent. Multiple, H-2-linked immune response genes control the level of cytotoxicity generated against TNP in association with H-2D region products when that response is generated against either trinitrobenzene sulfonate (TNBS)-modified cells or TNP-conjugated proteins. Human T cells can recognize TNP in association with determinants shared widely among other humans, polymorphic HLA-A and -B-locus-associated determinants distinct from HLA-A and -B. Studies of the cytotoxic responses of normal human lymphocytes to TNP-modified autologous cells have suggested that *Ir* genes control the response to TNP in association with human self-determinants. It is possible that TNP-modified tumor cells could be used to enhance immunity to unmodified tumor. (23 refs)

79-6083 The Role of Prothymocytes and the Thymic Microenvironment in the Pathogenesis of Thymic Lymphomas. (Eng) Waksal, S. D. (Tufts Cancer Res. Center, Tufts Univ. Sch. Medicine, Boston, MA); Robert, N.; Parkinson, D. R.; Morrissey, P. J.; Stout, R. D. *Proc Leukocyte Cult Conf* (12): 935-941; 1979.

Cell-to-cell interactions involved in prothymocyte/T-lymphocyte differentiation during the leukemogenic process were studied. After treatment with heterologous antiserum raised against mouse brain (anti-BAT serum) plus complement, the cytotoxic activity of untreated nu/nu spleen cells against RBL-5 lymphoma targets was dramatically reduced, whereas treatment with antiserum against

the alloantigen Thy 1.2 only partially reduced the cytotoxic activity. The expression of ecotropic virus in C57Bl/6 bone marrow after low level split dose irradiation was virtually abrogated after treatment with anti-BAT serum plus C'. The thymuses from young (6- to 8-wk-old) AKR mice expressed little gp70 on their surfaces, whereas thymocytes from 14- to 16-wk-old mice began showing increasing amounts, which finally resulted in expression on nearly all leukemic thymocytes. Similar expression was induced in C57Bl/6 thymocytes after a leukemogenic dose of radiation. AKR thymocytes cultured with thymus epithelium (TE) monolayers from young mice expressed high titers of ecotropic virus but no xenotropic virus. Cells cultured on TE monolayers derived from old AKR mice expressed not only high titers of ecotropic virus but also expressed xenotropic virus. This expression of xenotropic virus also appeared in vivo after 6 mo of age and was associated with events immediately preceding the appearance of thymomas. Thus, the appearance of xenotropic virus may be one of the co-factors required for leukemic transformation. The events associated with the differentiation of leukemic T-lymphocytes appear to involve a mosaic of interactions involving prothrombocytes, thymic epithelium, and endogenous C-type RNA viruses. (17 refs)

79-6084 HLA Alloantigens: Disease Association and Biologic Significance. (Eng) Mann, D. L. (Immunology Branch, NCI, NIH, Bethesda, MD 20205); Murray, C. *Semin Hematol* 16(4): 293-308; 1979.

Recent advances related to the association between human histocompatibility antigens (HLA) and disease are reviewed. The current concept of the fine structure of the human major histocompatibility complex (MHC) is discussed, as are investigations into some of the biochemical properties of MHC gene products. Data relating the recently described DRw antigens to specific disease states are also summarized, as are the results of some investigations into the functional properties of the MHC. Both the HLA and DRw antigens appear to play an important role in disease processes, and levels of two of the important complement components are coded for by genes of the MHC. Disease associations are high with the HLA-B locus antigens and even greater with the DRw antigens. Most diseases studied have a demonstrable component of autoimmunity, and complementation of action of a number of individual identical genes may give rise to the manifestation of the disease state. Different DRw antigens were shown to reflect clinical manifestation of two disease conditions: psoriasis and arthritis. However, these antigens have a common association and thus reflect or represent the common disease component in sicca syndrome. (98 refs)

79-6085 The Significance of Cancer After Renal Transplantation. (Eng) Montie, J. E. (Section Urology, Cleveland Clinic Foundation, Cleveland, OH 44106). *J Urol* 122(3): 298-299; 1979.

The significance of cancer development following renal transplantation is reviewed. This is a well documented occurrence and has immunologic implications. However, the incidence and severity of these malignancies are not of such a magnitude as to discourage the use of transplantation as a major treatment for chronic renal failure. Suppression of the immune surveillance system has been believed to be the cause of cancer after transplantation, but recent data suggest that this is not an adequate explanation. (9 refs)

- 79-6086 The Immune System of Animals and Its Role in Malignant Disease. (Ger) Pasternak, G. (No affiliation given). *Sitzungsber Akad Wiss DDR Math Naturwiss Tech* 6: 1-24; 1979.

Developments in the field of tumor immunology, particularly the search for a method of vaccination against cancer, are reviewed from 1953 to the present. The immunogenicity of chemically induced, transplantable tumors in an inbred mouse strain was shown in the early 1950's. Tumor-specific transplantation immunity induced in this animal model can be transferred to nonimmunized mice using lymphocytes from immunized mice. Tumors in different mice do not react with the same antigen even though the tumors were caused by the same carcinogen. Tumors induced by the same virus strain in different animals are antigenically cross-reactive, in contrast. Mechanisms of antigen recognition were studied extensively in the 1960's. The ability to produce antibodies appears to be genetically determined. Although immunization techniques developed in animals cannot ethically be directly applied to humans without further work, knowledge of immune systems has led to immunotherapy used with some success in human patients. Tumor antigens are currently used in diagnosis also. (33 refs)

- 79-6087 Molecular Approaches to Human Colon Cancer. (Eng) Kahan, B. D. (Dept. Surgery, Univ. Texas Medical Sch. at Texas, Houston, TX 77030); Rutzky, L. P.; Legrue, S. J.; Tom, B. H. In: *Oncodevelopmental Antigens*. Fishman, W. H., Busch, H., eds. (New York: Academic Press): Methods in Cancer Research Vol. 18, 409 pp.; 197-275; 1979.

Progress toward the elucidation of antigenic determinants that may provide a focus for measuring tumor-specific host immune performances and for designing and evaluating the results of immunotherapeutic maneuvers is reviewed. Despite chemotherapy, radiotherapy, and surgery, a large number of patients succumb to colon cancer. Immunotherapy offers the potential of harnessing the host immune response to control this neoplasm. In order to achieve a rational approach to specific immunotherapy, it is critical to define unique surface antigens distinctive for neoplastic cells. For this endeavor, the following are described: tissue-culture resources capable of cultivating a number of colonic cell lines and cloned subpopulations under a variety of conditions; chemical techniques to solubilize and purify membrane protein components; and immunologic tools to raise and characterize specific xenoantisera. Humoral factors controlling differentiation of colonic adenocarcinoma cells and of mediating intercellular adhesion are being investigated, utilizing hollow fiber tissue culture systems. Initial findings suggest the presence of unique tumor antigens that may represent suitable reagents for immunodiagnostic tools and for immunotherapeutic treatment modalities, in order to afford improved prospects for patient survival. (125 refs)

- 79-6088 Tumor Dormancy: A Review. (Eng) Alsabti, E. A. (Flat No. 5, Norfolk Terrace, Brighton BN1 3AD, England). *Tumor Res (Sapporo)* 13: 1-13; 1978.

The literature on tumor dormancy (TD), a state in which tumor cells persist in a clinically normal host for prolonged periods of time, is reviewed. Very few examples of TD have been demonstrated in animals, probably because of the short duration of most animal experiments. Maintenance of TD may involve the loss of exposed cell-surface targets for host effector mechanisms as

a result of antigenic modulation. During TD, oncogene expression may be suppressed by the action of host antitumor mechanisms acting at the cell surface, or alternatively, some surface receptors responsible for regulation of cell division that are usually concealed during tumor progression may become unmasked during antigenic modulation, leading to recovery of the control of cell division. Finally, TD could be established by the action of cytostatic rather than cytolytic host mechanisms. Tumor emergence (TE) may result from impairments in immune mechanisms due to senescence. The high incidence of TE during prolonged immunosuppression in humans is noteworthy. The low incidence of tumors in nude mice argues against this escape route, although B cells and macrophages in these mice may exert strong tumor-suppressive effects. Blockage of an effective host antitumor mechanism in vitro has also been proposed as a mechanism for TE in vivo. TE could also result from the absence of cell-surface tumor-associated antigens. In humans, the prolonged suppression of tumor metastasis and TD are probably mediated by a noncomitant immune response to tumor-associated antigens. TD can be diagnosed (1) prospectively by identifying tumor cells in tissue sections, isolating tumor cells from a host in clinical remission or identifying tumor markers such as carcinoembryonic antigen and (2) retrospectively by identifying emerging tumor cells as progeny of the original tumor cells. (66 refs)

- 79-6089 Teratocarcinoma and the Expression of Oncodevelopmental Genes. (Eng) Solter, D. (Wistar Inst. Anatomy and Biology, 36th and Spruce Sts., Philadelphia, PA 19104); Damjanov, I. In: *Oncodevelopmental Antigens*. Fishman, W. H., Busch, H., eds. (New York: Academic Press): Methods in Cancer Research Vol. 18, 409 pp.; 277-332; 1979.

Problems recently encountered in the study of teratocarcinoma are reviewed. Embryonal carcinoma cells are discussed with respect to their morphology, the origin of teratocarcinomas, teratocarcinoma-derived cell lines, and chromosomal studies of teratocarcinoma cells. The differentiation of embryonal carcinoma cells is also reviewed, with regard to somatic tissues, teratocarcinomas with a limited capacity for differentiation, yolk sac carcinomas, embryoid body formation, and the control of differentiation of embryonal carcinoma cells. Other topics include: the control of malignancy in embryo-derived teratocarcinomas; control of the expression of the malignant phenotype; and the products (surface, cytoplasmic and excreted, and nuclear proteins) of oncodevelopmental genes in embryonal carcinoma cells. (249 refs)

- 79-6090 Acute Myeloblastic Leukemia Considered as a Clonal Hemopathy. (Eng) McCulloch, E. A. (Ontario Cancer Inst., 500 Sherbourne St., Toronto, Ontario M4X 1K9, Canada); Howatson, A. F.; Buick, R. N.; Minden, M. D.; Izaguirre, C. A. *Blood Cells* 5(2): 261-282; 1979.

Laboratory data on acute myeloblastic leukemia (AML) are reviewed from the point of view that AML is a clonal hemopathy. The hematologic findings in AML describe the cellular composition of one or, at most, very few abnormal clones. The marked patient-to-patient variation in marrow granulopoietic progenitor frequency might be a consequence of the stochastic nature of clonal expansion rather than the result of the transforming event. It is suggested that in AML, only leukemic clones or progressed subclones progress. The characteristics of colonies in mitogen-stimulated cultures of leukemic peripheral blood indicate that the cells of origin of such colonies are a subpopulation of leukemic

blasts. A model for the development of AML specifies that the emergence of a blast component in an abnormal clone marks the transition from preleukemia to leukemia. The blast cell populations appear to be maintained independently of the myelopoietic components of leukemic clones. This independence may be based on progenitor self-renewal. (50 refs)

- 79-6091 Contact Inhibition and Malignancy. (Eng) Abercrombie, M. (Strangeways Res. Lab., 'Worts' Causeway, Cambridge, England). *Nature* 281(5729): 259-262; 1979.

The role of contact inhibition in influencing the behavior of malignant cells is reviewed. Invasion in culture may be assessed by a method involving confronted cultures in which two foci of explants are placed about 1 mm apart. Normal mouse muscle fibroblasts confronted with chick heart fibroblasts show a very high degree of obstruction, the invasion zone having a width of 20 μ m. Confronting each of six tumors (mouse sarcomas 311, BAS56, S180, FS9, MCIM and a mouse melanoma) with the chick fibroblasts results in invasion zones 130-290 μ m wide. Studies using both static (overlap index) and dynamic (time-lapse filming) methods of assessing contact inhibition demonstrate that it is a general feature of normal fibroblast collision. A conspicuous feature of contact inhibition in fibroblasts is the contraction undergone by the cell's front end. In nonreciprocal contact inhibition, the cell that is not inhibited proceeds while the cell that is inhibited retracts. In a quantitative study of tumors using the overlap index, a broad range of indices was found (2%-91%), whereas the indices of nonmalignant cells were in the 3-19% range. Thus malignant cells are characterized by their broad variability compared to normal cells. It is not clear how a lowered homotypic contact inhibition of malignant cells contributes to their invasiveness. Both reciprocal and nonreciprocal invasion are exhibited by the various tumors studied. In addition to contact inhibition, variable adhesiveness might play a part in determining invasiveness; other factors may also play a minor role. (19 refs)

- 79-6092 DNA Repair Defects and Chromosome Instability Disorders. (Eng) Polani, P. E. (Prince Philip Res. Labs., Guy's Hosp. Medical Sch., London, England). *Ciba Found Symp* (66): 81-133; 1979.

The clinical, chromosomal, and general molecular aspects of four autosomal recessive disorders are reviewed: xeroderma pigmentosum (XP), Fanconi anemia (FA), ataxia telangiectasia (AT), and Bloom disease (BS). Between 80%-90% of XP patients have a defect, demonstrable at cellular level, of excision of DNA lesions induced by UV, while the remainder have a cellular error of postreplication repair. XP cells are also deficient in repairing DNA damage caused by some chemical mutagens. AT is heterogeneous clinically and genetically. It is characterized by γ -radiation sensitivity, which generally involves an inability to remove DNA lesions. In many cases, a chromosomally marked cellular clone is present. In BS there seems to be a defect consisting of slow DNA chain maturation during synthesis with the formation of an excessive number of sister chromatid exchanges. In FA, the cellular defect apparently consists of faulty removal or repair of cross-links in the DNA. All four disorders behave as rare autosomal recessives, and all are characterized by a tendency toward malignancy. Patients with XP develop skin cancers in early life and often malignant melanomas. In the other three disorders, leukemia and related proliferative disorders are a frequent cause of death. There is some evidence of an increased risk of malignancy in heterozygotes who carry the FA and AT genes. (12 refs)

- 79-6093 Multiple Endocrine Neoplasia. (Fre) Pradalier, A. (Service due Pr J. Dry, Hopital Rotschild, 43 bd de Picpus, 75012 Paris, France); Roger, M. *Med Int* 14(5): 329, 331-332, 334-338; 1979.

The literature on multiple endocrine neoplasia (MEN) is reviewed. Two types of MEN are distinguished. Wermer's syndrome accounts for approx 80% of all cases of MEN; it can involve the parathyroid gland, pancreas, and less often, the pituitary gland, and is often associated with carcinoid tumor, mainly in the lungs. Sipple's syndrome involves medullary carcinoma of the thyroid, pheochromocytoma, and parathyroid tumor. The hypothesis attributing MEN to the hyperfunction of the parathyroid gland, islands of Langerhans, and pituitary gland has not been confirmed. According to one plausible hypothesis, MEN is genetically determined by a pleiotropic gene with autosomal dominant heredity and variable degrees of expression. According to another hypothesis, MEN is considered a dysplasia of the neuroectodermal tissue. (33 refs)

- 79-6094 Pathology of Gastric Carcinoma. (Fle) Geboes, K. (Laboratorium voor Histochemie en Cytochemie, A.Z. St. Rafael, Louvain, Belgium); Desmet, V. *Tijdschr Gastroenterol* 21(5): 367-378; 1979.

The pathology and classification of gastric carcinoma are reviewed. The presence of precancerous lesions implies an increased risk of malignant transformation. These lesions include gastric polyps, mucosal alterations in pernicious anemia, and intestinal metaplasia. The risk of gastric cancer is also increased after partial gastrectomy. Carcinoma in situ consists of malignant cells without signs of invasion. The differential histological diagnosis of carcinoma in situ, epithelial atypia, and adenoma may be difficult. (21 refs)

- 79-6095 A Rationale for the Loss of Growth Control During Experimental Bladder Carcinogenesis. (Eng) Reese, D. H. (Dept. Urology (D-1), Univ. Miami Sch. Medicine, P.O. Box 016217, Flagler Station, Miami, FL 33101); Politano, V. A. *Med Hypotheses* 5(9): 1007-1015; 1979.

The loss of growth control associated with the early phase of experimentally induced bladder cancer is reviewed, and an explanation for this phenomenon is offered. It is proposed that the focal loss of alkaline phosphatase activity and increased cell proliferation occurring in urothelium following exposure to carcinogens are manifestations of a defective interaction between glucocorticoid hormone and urothelium, and that this defect is an underlying cause for the loss of growth control occurring during bladder carcinogenesis. In this manner, the urothelium loses, at least temporarily, the ability to respond to glucocorticoid hormone; this phenomenon may involve a defect in the receptor mechanism. The underlying cause of other benign proliferative lesions of the urothelium could also be the defective interaction between glucocorticoid and urothelium. The defect in these cases would be reversible. The appearance of a defect in the interaction between glucocorticoid and urothelium could, therefore, be a common response to injurious agents and may be part of a mechanism that facilitates regenerative hyperplasia following urothelial injury. (54 refs)

- 79-6096 Neuroendocrinological Aspects of Ovarian Tumors as Dissipative Structures. (Pol) Klimek, R. (Klinika En-

dokrynologii, Instytut Ginekologii i Poloznictwa AM, ul. Koper-nika 23, 31-501 Krakow, Poland). *Patol Pol* 30(2): 187-193; 1979.

The thermodynamic model of neoplastic processes is discussed with special reference to ovarian tumors. In contrast to other diseases, the formation of biologically dissipative structures in the course of carcinogenesis is the essence of the neoplastic process. The development of these structures is linked to the dissipation of energy and matter from other parts of the body, which markedly enhances entropy and thus leads to early death and to the depletion of the body's source of energy and matter. (7 refs)

- 79-6097 Occupational Health and Coal Conversion. (Eng) Young, R. J. (Natl. Inst. Occupational Safety and Health, Cincinnati, OH); Evans, J. M. *Occup Health Saf* 48(6): 22-26; 1979.

Epidemiologic evidence indicates that workers routinely exposed to products of combustion or distillation of bituminous coal are at increased risk of developing cancers of the skin, lungs, urinary tract, larynx, nasal sinuses, stomach, intestine, pancreas, and hematopoietic organs. The National Institute for Occupational Safety and Health has made a first attempt to develop occupational health and safety for the US Synthetic Fuels Program. The use of pilot and demonstration plants in such an undertaking are discussed. Occupational health and safety must be given adequate consideration in the developmental stages of coal conversion. (33 refs)

- 79-6098 The Role of Fusarium Mycotoxins in the Aetiology of Tumours of the Digestive Tract and of Certain Other Organs in Man and Animals. (Eng) Schoental, R. (Dept. Pathology, Royal Veterinary Coll., Univ. London, London, England). *Front Gastrointest Res* 4: 17-24; 1979.

The possible role of Fusarium mycotoxins in the etiology of human and animal tumors is reviewed. Some diseases and tumors of the digestive tract in man and lower animals may be caused by trichothecenes (eg, T-2 toxin), the irritant secondary metabolites of Fusaria and other species of field fungi which contaminate cereals and other foodstuffs. The estrogenic metabolites of Fusaria, including zearalenone, may be involved in abnormalities and neoplasias of the gonads and related organs. The reported unpredictable variations in the incidence of tumors in laboratory rats, mastomys, and mice might be explained by occasional heavy contamination of the diet with mycotoxins. T-2 toxin may also be involved in the etiology of diseases and tumors considered as spontaneous in various species, including man. T-2 toxin could be effective per se or, acting in conjunction with other factors, could contribute to the multifactorial origin of cancer. (32 refs)

- 79-6099 Epidemiological Features of Gastrointestinal Cancer. (Eng) Burkitt, D. P. (Unit Geographical Pathology, St. Thomas's Hosp., London SE1 7EH, England). *Front Gastrointest Res* 4: 86-95; 1979.

The epidemiological features of various gastrointestinal cancers are reviewed. Tumors in different parts of the alimentary tract have characteristic different geographical, ethnic, sexual, and socioeconomic distributions. Among the oral cancers, epithelioma of the cheek is closely associated with the chewing of pan leaf in

which substances such as lime, tobacco, and betel-nut are folded. Esophageal cancer, which shows variations in incidence associated with geography, ethnic background, and sex, may be caused by different factors in different geographical regions. The etiology of gastric cancer, which also varies with geography, ethnic background, and sex, is also as yet undetermined. Primary liver cancer exhibits a high prevalence over much wider geographical regions than do esophageal or gastric cancer. Current evidence suggests that both aflatoxin and hepatitis B infection may be involved in its etiology. The incidence of colorectal cancer varies according to the extent of economic development and the influence of modern western culture. Both excessive consumption of fat and insufficient fiber may play a role in the pathogenesis of this cancer. (52 refs)

- 79-6100 Gastrointestinal Cancer. Genetics and Genetic Markers. (Eng) McConnell, R. B. (Broadgreen Hosp., Thomas Drive, Liverpool, L14 3LB, England). *Front Gastrointest Res* 4: 134-141; 1979.

The influence of heredity on the etiology of gastrointestinal (GI) cancer is reviewed. This influence can be considered under four headings. Dominant inheritance with high cancer risk is seen in individuals with tylosis, polyposis coli, discrete colonic polyps, and 'cancer family' syndrome. The GI cancers in such individuals develop due to the effects of a single gene in a Mendelian dominant manner. The following five conditions are also inherited in a dominant manner and are associated with a less marked but nevertheless significantly increased cancer risk: hereditary pancreatitis, Peutz-Jeghers syndrome, hemochromatosis, Wilson's disease, and multiple endocrine adenomatosis. In the following conditions, inheritance is probably multifactorial due to the effect of several genes plus a considerable environmental influence: pernicious anemia, celiac disease, Crohn's disease, ulcerative colitis, chronic calcifying pancreatitis, and cirrhosis of the liver. In addition, the relatives of persons with stomach cancer are at increased risk for this disease, as are persons of blood Group A. A four-fold increase in the risk of colon cancer was found among relatives of persons with colon cancer and among relatives of persons with ulcerative colitis or Crohn's disease. (23 refs)

- 79-6101 Carcinogenesis of Gastrointestinal Cancer. (Eng) Hill, M. J. (Central Public Health Lab., Colindale Ave., London NW9, England). *Front Gastrointest Res* 4: 1-16; 1979.

Epidemiological studies of gastric and colorectal cancer, the concepts of carcinogenesis evolving from these studies, and data for and against the hypotheses are reviewed. A correlation between nitrate intake and gastric cancer incidence has been demonstrated in Colombia and suggested in Japan. A model has been proposed for gastric carcinogenesis which involves a series of mutations and cell transformations leading to gastric metaplasia and then to carcinoma and mediated by nitrosamines or N-nitroso compounds formed endogenously. Studies of colorectal cancer tend to support a correlation with fat or meat intake, but the results are not conclusive. Three diseases predispose to colorectal cancer: adenomatosis coli, ulcerative colitis, and single or multiple adenomas. Other cancers, eg, cancer of the breast, endometrium, ovary, and prostate, which have been postulated to have a steroid hormonal etiology, are associated with colorectal cancer; thus the latter may also have a steroidal etiology. Evidence for a causal role for bile acids in colorectal cancer has been obtained from studies of several populations, but the nature of the bacterial metabolite

involved is not clear. Most, if not all, colorectal carcinomas arise in preformed adenomas; the risk of carcinoma development depends therefore on the risk of developing adenoma and on the risk of that adenoma progressing to malignancy. In both gastric and colorectal cancer, multi-step etiologies have been proposed that are suitable to experimental verification. (73 refs)

- 79-6102 Current Trends in Toxicological Research. (Eng) Allison, A. C. (Cell Pathology Div., Clinical Res. Centre, Harrow, Middlesex, England). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 387-401; 1978.

Current trends in toxicological research are reviewed. Topics include interactions of toxins with membranes, carcinogens and the lung, effects of inhaled polyvinyl chloride particles, analytical electron microscopy of toxic dusts, the toxic effects of asbestos, the effects of silica and asbestos on macrophages, tests with cell cultures as predictors of toxicity, granulomatous reactions, trends in academic toxicology research, and the applications of toxicology research. Carcinogen metabolism in vivo and enzymatic repair of carcinogen-induced damage are discussed. (31 refs)

- 79-6103 A New Theory of Carcinogenesis. (Eng) Holliday, R. (Natl. Inst. Medical Res., The Ridgeway, Mill Hill, London NW7 1AA, England). *Br J Cancer* 40(4): 513-522; 1979.

A new theory of carcinogenesis is proposed. Although many carcinogens are mutagens, there is no direct evidence that the cancer-cell phenotype is the result of gene mutation and malignant cells can arise or revert to the normal phenotype in the absence of mutation. It is suggested that damage to DNA followed by repair triggers the epigenetic changes in gene expression responsible for malignancy. It was previously suggested that methylation of specific DNA sequences adjacent to structural genes determines whether or not transcription will occur and that specific methylases provide a basis for the control of gene expression in differentiated cells. It is now known that damage to DNA followed by repair, just before or just after DNA replication, can lead to the loss of methyl groups. This can induce a switch in gene activity that is heritable but potentially reversible. This theory accounts for the known large difference in the probability of malignant transformation in cells of rodents and large mammals. There is evidence that excision repair is more efficient in cultured fibroblasts from large long-lived animals than from small short-lived ones. (58 refs)

- 79-6104 Impact on Drugs, Food, and Environment. (Eng) Worden, A. N. (Huntingdon Res. Center, Huntingdon, Cambridgeshire, England). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 415-434; 1978.

Modifications based on toxicological research could help to diminish hazards such as those associated with smoking, including carcinogenicity. Cancer associated with inhalation of combustion

products containing known carcinogens has decreased in the United Kingdom since 1955, and the hazards of exposure to mesothelioma-inducing asbestos particles could be reduced by reducing cigarette smoking. The predictive use of animal experimentation must be linked with postmarketing or postexposure monitoring and surveillance. Among the human environmental carcinogens that have been "predicted" from animal experimentation are mustard gas, vinyl chloride, stilbestrol, and aflatoxin. Foods constitute the most complex group of substances from the standpoint of predictive toxicology. It is suggested that although toxicity testing might delay and add to the expense of the clearance of new medicines, it does not ultimately deprive mankind of valuable therapeutic agents. (85 refs)

- 79-6105 Toxicological Aspects of the Air We Breathe. (Eng) Lawther, P. J. (M.R.C. Toxicology Unit, Clinical Section, St. Bartholomew's Hosp., London, England). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 15-34; 1978.

Toxicological evaluations of air pollutants, especially in the United Kingdom, are reviewed. Since passage of the Clean Air Act (1966), a series of studies suggests that the concentration of benzo(a)pyrene (BP) in the air is 1/10 of what it was 25 yr ago. There are also signs that the urban excess of lung cancer is declining. An association has been found between occupation in or residence near asbestos works and pleural mesothelioma. There is evidence that exposure need be only minute and that the resulting tumors may not be clinically manifest for up to 40 yr. Urban air contains many metals in trace amounts, some of which have been associated with cancer among occupational groups, eg, nickel, chromium, and beryllium. Concern about pollution of the communal air by industrial carcinogens has also been stimulated by the induction of angiosarcoma in workers using vinyl chloride monomer. Carbon monoxide exerts deleterious effects on the CNS and cardiovascular system. The effects of high doses of lead in adults and children are well-known, but there is conflicting evidence about the subclinical effects of body burdens formerly thought to be insignificant. (49 refs)

- 79-6106 Some Remarks on General Principles for Prevention of Toxic Hazards. (Eng) Truhaut, R. (Centre de Recherches Toxicologiques de la Faculte des Sciences Pharmaceutiques et Biologiques, Universite Rene Descartes, Paris, France). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 369-380; 1978.

The role of toxicology as a preventive science is emphasized. Toxicological evaluation is achieved in three steps: (1) collection and (2) interpretation of facts, and (3) decision-making. The first stage should involve collaboration between experimental toxicologists and clinicians and/or epidemiologists. While the ideal rule for prevention would be to exclude hazardous chemicals from the environment, such measures are not always possible; but the amount of pollutants to which people are exposed should be reduced as much as possible. In the case of industrial chemicals of high toxicity, efforts should be directed at replacing them with functionally equivalent chemicals which are nontoxic or at least much less toxic. Very often, the toxicity of a substance may be due to the im-

purities it contains; thus rigorous purity standards should be enforced. The determination of thresholds and permissible limits is important for occupational chemicals, atmospheric pollution, and food additives. The promotion of suitable health education for exposed individuals and particularly for those in the chemical industry is stressed. (13 refs)

- 79-6107 Toxicology in a Cold Climate. (Eng) Somers, E. (Environmental Health Directorate, Health Protection Branch, Dept. Natl. Health and Welfare, Ottawa, Canada). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 75-86; 1978.

The role of toxicology in evaluating environmental hazards and setting standards in Canada is discussed. Evaluation of human health hazards is based on the following: (1) concentration of the substance to which man is exposed; (2) toxic properties of the substance; (3) stability of the substance in the environment and in tissues; (4) accumulation in tissues; and (5) interactions with other substances. There are two options for achieving control over a potentially hazardous environmental agent: (1) restriction of the release of the agent, eg, setting emission standards for air or water; and (2) control of the agent itself. Risk-cost-benefit considerations, in spite of their limitation, have a useful place in decisions relating to the choice of regulatory strategies. Risk-benefits assessments made in Canada in recent years are illustrated by the establishment of a guideline for the mercury content in fish and by the conclusion that present levels of use of nitrilotriacetic acid in detergents do not pose an unacceptable health hazard to the public. (10 refs)

- 79-6108 General Principles of Preventive Toxicology. (Eng) Izmerov, N. F. (Inst. Industrial Hygiene and Occupational Diseases, Moscow, USSR); Sanotski, I. V. In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 359-368; 1978.

General principles of preventive toxicology are reviewed. A variety of theoretical investigations, principles, and methods for the evaluation of toxicity have been developed, including the principle of synchronization of toxicological investigations with the stages of technological development and production of new compounds. The stage investigation principle allows evaluation of chemical substances and technological processes before their use in production and distribution in the environment. The principle of threshold for all forms of chemical events (such as mutagenesis and carcinogenesis) and the principle of unity of molecular, structural, and functional changes as the basis for differentiation between effect and harmful effect are discussed. (9 refs)

- 79-6109 Toxicological Aspects of the Water We Drink. (Eng) Benes, V. (Inst. Hygiene and Epidemiology, Prague, Czechoslovakia). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 35-45; 1978.

Current approaches to the assessment of toxic risk posed by trace chemical substances in drinking water are reviewed. Acceptable daily intake (ADI) values may be useful in considering possible risk from pesticide residues in drinking water. However, ADI values have not been established for a number of substances. In these cases, a preliminary risk assessment is made by comparing actual intake with available toxicological data. Exposure to polychlorinated biphenyls via drinking water (2 nanograms/liter) can be considered relatively slight provided further contamination does not occur. For carcinogenic polycyclic aromatic hydrocarbons (PAH) the limit of 0.2 µg/liter has been derived from the background levels in ground water. PAH are present in the soil and vegetables as well as in water. For the cumulative metals (lead, mercury, and cadmium) only provisional tolerable weekly intakes for humans have been estimated: for lead, 50 µg/kg; for mercury, 5 µg/kg; and for cadmium, 6.7-8.3 µg/kg. Zinc, selenium, and cobalt appear to exert a protective effect against the toxicity of cadmium and mercury. This interaction makes it important to consider simultaneous exposure to these elements for accurate assessment of risk. A serious problem is associated with the presence of nitrates in drinking water since this contamination may lead to the formation of N-nitroso compounds. Trace amounts of N-nitroso pesticide derivatives have been found in the drinking water of one US city. Assessment of possible human carcinogenic risk from chlorinated hydrocarbons in drinking water is difficult due to limited data from experimental studies and lack of appropriate epidemiological studies. (60 refs)

- 79-6110 Toxicological Aspects of the Food We Eat. (Eng) Poulsen, E. (Inst. Toxicology, Natl. Food Inst., Copenhagen, Denmark). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 47-59; 1978.

Methods used in evaluating food toxicity are reviewed; and natural food components, food additives, and food contaminants are considered in relation to toxicology. Toxicological studies required to evaluate food safety and to estimate an acceptable daily intake (ADI) for humans include acute toxicity tests, short- and long-term studies in animals, and observations in humans wherever possible. The evaluation of nitrates and nitrites as food additives illustrates the way toxicology has tried to fulfill its role as a predictive science. Nitrite can convert certain nitrogen-containing compounds to N-nitroso compounds, many of which are carcinogenic in low doses in a variety of animal species. It must be assumed that these compounds are generally carcinogenic in man. Studies have recently indicated that nitrate levels in certain vegetables (spinach, lettuce, celery) and drinking water may also present a potentially serious problem. The level of nitrite in the saliva is significantly higher and the blood content of nitrosamines is increased following ingestion of these high-nitrate foods. Butylated hydroxytoluene (BHT), a widely used food antioxidant, increased the incidence of lung tumors induced by diethylnitrosamine and by urethane in mice. The effect of BHT in animal experiments is influenced by the amount and relative concentrations of normal dietary components, eg, protein and fat. (33 refs)

- 79-6111 Environment and Cancer. (Spa) Francia Vina, J. M. (Centro Demostracion Sanitaria, Talavera de la Reina, Toledo, Spain); de la Pena de Torres, E. *Rev Sanid Hig Publica (Madr)* 52(11/12): 1435-1454; 1978.

This review of studies concerning environmental carcinogens includes investigations of geographic variations in cancer incidence, immigrant studies, and laboratory data on environmental carcinogens. The major environmental carcinogens are the aflatoxins, polycyclic aromatic hydrocarbons, nitrosamines, UV rays, and ionizing radiation. In humans, the effective and ineffective doses of chemical carcinogens have not yet been established. It is difficult to assess the significance of additional exposure to ubiquitous environmental carcinogens, such as polycyclic aromatic hydrocarbons, nitrosamines, and mycotoxins. In 1976, the cancer mortality in Oviedo Province amounted to 1,862 cases (1,060 men and 802 women). Stomach cancer accounted for 16.5%, lung cancer for 16.1%, small intestinal cancer for 3.8%, colorectal cancer for 5.8%, liver and gallbladder cancer for 8.7%, pancreatic cancer for 2.8%, cancer of other gastrointestinal organs for 2.3%, laryngeal cancer for 3.1%, urinary bladder cancer for 1.6%, renal cancer for 2.2%, prostate cancer for 5.9%, breast cancer for 6.3%, uterine cancer for 2.4%, ovarian cancer for 1.9%, brain tumors for 2.3%, bone tumors for 0.85%, malignant hematological diseases for 8.5%, buccal and pharyngeal tumors for 2.4%, esophageal tumors for 2.3%, and other tumors for 5.6%. - 79-6112 World PCBs MAP: Storage and Effects in Man and His Biologic Environment in the 1970s. (Eng) Wassermann, M. (Dept. Occupational Health, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Wassermann, D.; Cucos, S.; Miller, H. J. *Ann NY Acad Sci* 320: 69-124; 1979.

The epidemiologic features of the polychlorinated biphenyls (PCBs) stored in human tissues and in the biologic environment are reviewed, as are some of the effects of PCBs. Information concerning PCB residues in marine organisms, fresh water and marine fish, birds, avian eggs, terrestrial animals, the adipose tissue of the general human population, and human plasma and milk is presented. The effects of PCBs on reproduction in aquatic organisms, birds, and terrestrial mammals are discussed, as are the effects of these compounds on development and growth, liver morphology, enzyme activity, drug and lipid metabolism, liver porphyrins, hormones, the immunologic defense system, and the nervous system. Also discussed are the dermatologic and tumorigenic effects of PCBs. Hepatocellular adenomas, carcinomas, and adenofibrosis have been induced by commercial mixtures of PCBs and pure biphenyl compounds in mice; these neoplasms have also been induced in rats by technical mixtures of PCBs. Tumor incidence increases with dosage. PCBs may act as promoters of experimental liver carcinogenesis in some cases and may inhibit carcinogenesis associated with some promoters (eg, diethylnitrosamine). These compounds have caused hyperplasia of hair follicle epithelium and severe hypertrophic and hyperplastic gastritis in adult monkeys. Malignant melanomas have been found in 2/31 persons in one group and 1/41 persons in another group of individuals exposed occupationally to PCBs. However, these workers were also exposed concomitantly to other carcinogens, particularly epoxides. (340 refs)

- 79-6113 Environmental Cancer: Interplay Between Laboratory and Field Studies. (Eng) Nelson, N. (Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY). In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March-2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 327-337; 1978.

The respective roles of epidemiologic and laboratory studies in identifying specific factors leading to a particular cancer are reviewed. The alkaline chromates have been identified as the agents of probable greatest importance in cancer induction by chromium. Extensive epidemiologic studies on the consequences of childhood scalp irradiation for control of ringworm were augmented by laboratory studies that identified the dose to various biological targets from the procedure. These studies led to the identification of eight thyroid adenomas in 1,500 children exposed at the very low dose of 6 rads to the thyroid. Cigarette smoking has been linked to lung cancer in many studies, but the specific carcinogenic factors have not yet been identified precisely. Cigarette smoke contains promoting and cocarcinogenic agents that substantially enhance the activity of the carcinogenic polynuclear hydrocarbons, and the combination of all these factors may produce the carcinogenic effects of cigarette smoke. Vinyl chloride and bis(chloromethyl)ether were identified as carcinogens in the laboratory in the absence of epidemiologic evidence. Subsequently, definitive epidemiologic studies confirmed that occupational cancers had resulted from exposure to these chemicals. A clear association was established between lung cancer and occupational exposure to the chloroethers. Dimethyl carbamoyl chloride has also been identified as carcinogenic in related studies. (22 refs)

- 79-6114 Need to Pursue New Leads in the Epidemiology of Colorectal Cancer. (Eng) Graham, S. (Dept. Sociology, State Univ. New York at Buffalo, Buffalo, NY 14261); Haenszel, W.; Bock, F. G.; Lyon, J. L. *J Natl Cancer Inst* 63(4): 879-881; 1979.

The literature concerning the epidemiology of colorectal cancer (CRC), particularly that concerning the relationship between diet and cancer, is reviewed, and the need for further research is stressed. A clear case has not been established for the theories that the risk of CRC is related to decreased fiber and increased fat consumption. There have been few epidemiologic studies, and most that have been done have involved small numbers of subjects. An investigational model involving a prospective study of normal persons is needed. Since such a model would involve questioning subjects regarding dietary habits, further research on the validity of interviewing in regard to diet is required. Specific animal studies of CRC and epidemiologic interview and questionnaire studies cannot establish a protective effect for cruciferous vegetables. Epidemiologists should examine the possible factors that could inhibit CRC development and should use the more traditional approach of seeking factors that might predispose to its development. (40 refs)

- 79-6115 Occupational Lung Disease: How Significant a Problem? (Eng) Strasser, A. L. (Dept. Community Health and Occupational Medicine, Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY). *Occup Health Saf* 48(6): 16-19; 1979.

The significance of occupational lung disease is reviewed, with emphasis on the occurrence of black lung, asthma, and lung cancer among those employed in particular occupations. Lung cancer causes more deaths in men than any other malignancy, and its incidence is increased among workers exposed to asbestos, arsenic, or chromates. The incidence of occupational lung cancer can be reduced by good pre-placement examinations and standards, good industrial hygiene and proper ventilation, and elimination of smokers from occupations involving exposure to certain chemicals. (no refs)

- 79-6116 Case-Control Studies on the Effect of Sex Steroids on Women and Their Offspring. (Eng) Janerich, D. T. (Cancer Control Bureau, New York State Dept. Health, Albany, NY 12237); Glebatis, D.; Flink, E.; Hoff, M. B. *J Chronic Dis* 32(1/2): 83-88; 1979.

The use of the case-control method for studies of birth defects and breast tumors in relation to exposure to female sex hormones is discussed. Case-control studies are the strongest analytic epidemiological tools for the study of causal mechanisms of diseases that are rare or that have long latency periods, but they have two major handicaps: (1) relative risk is expressed in terms of exposure among the diseased; and (2) exposure is ascertained after the disease has occurred. Both of these handicaps can be overcome by careful study design. In an ongoing case-control study of breast disease and oral contraceptive use, two characteristics were considered potential confounding factors: (1) the dramatic increase in oral contraceptive use in the mid-1960's; and (2) the protective effect of early first pregnancy against breast cancer. A preliminary case-control study confirmed the importance of considering age at first pregnancy as a risk factor in young women and indicated that male first offspring had a greater effect on the risk associated with age at first pregnancy than female first offspring. Based on this information, the study of the role of oral contraceptives in breast cancer was designed so that the controls were matched by present age and age at first birth. The potential confounding effects of benign breast disease and sex of the offspring will be dealt with in the analysis of the data. (15 refs)

- 79-6117 A Review of the Epidemiology of Human Breast Cancer. (Eng) Kelsey, J. L. (Dept. Epidemiology and Public Health, Yale Univ. Sch. Medicine, 60 College St., New Haven, CT 06510). *Epidemiol Rev* 1: 74-109; 1979.

Major aspects of the epidemiology of breast cancer are reviewed. The annual age-adjusted incidence and mortality rates for breast cancer among women in the US for 1973 through 1976 were 84.9 and 27.7 per 100,000 women, respectively. Both incidence and mortality rates vary greatly throughout the world, and within the US, rates are higher in urban than in rural areas and in the North as compared to the South. Tumors occur more frequently in the left breast than in the right. Large relative risks of breast cancer are associated with increasing age, a history of bilateral premenopausal breast cancer in a first degree relative, a history of breast cancer in the contralateral breast, and residence from an early age in North America compared with residence in Asia. Moderate relative risks are associated with previous oophorectomy, increasing age at first birth, a history of fibrocystic breast disease, previous exposure of the chest to high levels of radiation, a history of breast cancer in any first degree relative, obesity, and previous cancer in the ovary or endometrium. Age at menarche, age at menopause, marital status, place of residence, and race are associated with small but real differences in risk. The relative rarity of breast cancer in men makes it difficult to identify any but the strongest risk factors in this group. (358 refs)

- 79-6118 Cervical Carcinoma Today: New Aspects of Diagnosis and Treatment. (Ger) Pfleiderer, A. (Universitäts-Frauenklinik, Hugstetter Strasse 55, D-7800 Freiburg i. Br., W. Germany). *Ther Umsch* 36(6): 484-490; 1979.

Contemporary diagnostic and therapeutic aspects of carcinoma of the uterine cervix are discussed. Cervical carcinoma is the second most frequent carcinoma in women, and it is the most frequent

carcinoma in women aged <40 yr. In 1976, the incidence of cervical carcinoma (including carcinoma in situ) was 45/100,000 in South Wurttemberg-Hohenzollern, and 66/100,000 in the age bracket 30-35 yr. In 1976, 2,241 cases of malignant tumors of the uterine cervix were diagnosed in Baden-Wurttemberg; 1,034 of them were in situ carcinomas. The incidence of cervical dysplasia is highest in the age bracket 25-30 yr; that of carcinoma in situ, in the age bracket 35-40 yr; that of microcarcinoma, in the age bracket 40-45 yr; and that of invasive carcinoma, in the age bracket 56-67 yr. Cervical carcinoma can develop at the boundary between the squamous epithelium of the ectocervix and the glandular epithelium of the endocervix. Smegma (probably due to the presence of certain proteins or viruses, eg, herpesvirus) or sperm can lead to a malignant transformation of the reserve cells especially in very young women (under the age of 17 yr). The retracting epithelium is replaced by metaplastic squamous epithelium in which the malignant transformation takes place (atypical metaplasia). Dysplasia can develop after a few years. In many cases, the dysplastic epithelium can degenerate and be rejected and replaced by normal epithelium. (no refs)

- 79-6119 Ovarian Carcinoma. (Ger) Spechter, H. J. (Abteilung Geburtshilfe, Städtisches Krankenhaus, Robert-Koch-Strasse 1, D-8003 Landshut, W. Germany). *Ther Umsch* 36(6): 518-523; 1979.

The incidence, etiology, pathology, and attempts at early diagnosis of ovarian carcinoma are reviewed. Mortality from ovarian carcinoma varies with location (deaths/100,000 women, 1.7 in Japan vs 11 in Denmark), but the causative factors have not been clarified. Ovarian tumors can be divided into epithelial and special types (eg, germ-cell, connective tissue, adrenal-rest cell tumors); each type includes many subtypes. The serosal tumors grow and metastasize much faster than the mucinous and endometrial carcinomas. Thus the prognosis varies with the tumor type. Only the hormonally active tumors that lead to irregular or postmenopausal bleeding are often diagnosed at early stages. Most patients have no characteristic symptoms until their ovarian malignancy is advanced. No screening test (cytological smear, blood antigen) has yet proven reliable for early diagnosis. (29 refs)

- 79-6120 Ovarian Tumors after Hysterectomy. (Ger) Roemer, V. M. (Universitäts-Frauenklinik, Tübingen, W. Germany); Neeser, E.; Peters, F. D.; Wehle, H. E. *Gynaekol Rundsch* 19(Suppl. 1): 107-123; 1979.

The incidence of ovarian tumors in hysterectomized women is reviewed. The advisability of prophylactic ovariectomy during hysterectomy is discussed. Calculations indicate that if bilateral ovariectomies (BLO) were routinely performed on women over 40 yr of age who were undergoing hysterectomy for benign disease, the incidence of ovarian carcinoma could be reduced approx 20%. These calculations also indicate that at least 700 BLO would be required to prevent 1 ovarian carcinoma. The psychological and physiological consequences of prophylactic ovariectomy must be considered before such a procedure is recommended. The incidence of ovarian tumors (benign or malignant) is apparently not greater in women who have undergone simple hysterectomy than in the general population. The calculated effect of prophylactic BLO depends on many variables, including age at which hysterectomy is done, frequency of hysterectomy in the population, and incidence of ovarian carcinoma. This incidence (per 100,000 population) varies from 2.8 in Japan to 15 in Scandinavia and increases

markedly with age at least to 80 yr. The av age at diagnosis is approx 60 yr. As a result of these considerations, routine ovariectomy (adnexectomy) is recommended for women undergoing hysterectomy after 50 yr of age and may be advisable for younger women who are considered to have an increased risk of ovarian carcinoma. Estrogen substitution therapy is recommended if premenopausal hysterectomy is done. Although the risk of breast cancer may be slightly increased in women on this therapy, at least one study shows their life expectancy to be greater than that of women with intact genitals and no hormone therapy. (76 refs)

79-6121 Ovarian Tumors with Special Reference to Dogs. (Pol) Zembrzycka, H. (Instytut Chorob Niezakażonych, Wydział Weterynaryjny SGGW-AR, ul. Grochowska 272, 03-849 Warsaw, Poland). *Patol Pol* 30(2): 245-251; 1979.

Ten ovarian tumors observed in dogs at a Veterinary Institute during a 10-yr period are described. Cystadenoma was diagnosed in 6 dogs aged 3-12 yr, cystadenocarcinoma in 2 dogs aged 8 and 12 yr, respectively, theca-cell tumor in a 6-yr-old dog, and cystadenoma in another 6-yr-old dog. A review of the literature shows that ovarian tumors account for about 1.4% of all tumors in dogs, compared with 1.8% in horses, and <0.7% in pigs, and 4% in ruminants in general. There is a species-specific predisposition to certain types of ovarian tumors in animals; the most frequent ovarian tumors are granulosa-cell tumors in cattle, granulosa-cell tumors and cystadenoma in dogs, and teratoma in horses. Although ovarian tumors occur in animals at all ages, the risk increases with age. (9 refs)

79-6122 The Drama of Ovarian Carcinoma. (Ger) Hauser, G. A. (Frauenklinik des Kantonsspitals, CH-6004 Lucerne, Switzerland). *Ther Umsch* 36(6): 532-537; 1979.

The general epidemiologic and diagnostic problems encountered with ovarian carcinoma are reviewed. Ovarian carcinoma accounts for about 20% of all carcinoma of the genitals, but it has the most unfavorable prognosis of all these tumors; the cure rate is only 24%. Menopausal bleeding, postmenopausal ovary syndrome, and a small number of childbirths imply increased risk of ovarian carcinoma. (11 refs)

79-6123 Epidemiology and Pathology of Ovarian Carcinoma. (Ger) Torhorst, J. (Institut für Pathologie der Universität Basel, Schönbeinstrasse 40, CH-4056 Basel, Switzerland); Almendral, A. C. *Ther Umsch* 36(6): 524-531; 1979.

The epidemiology and pathology of ovarian carcinoma are reviewed. Ovarian carcinoma accounts for approx 80% of all malignant ovarian tumors. The incidence (per 100,000 women) shows great geographic differences, ranging from 2.8 in Japan to 15.1 in Sweden, and it is substantially higher in Europe and North America than in Asia, Africa, and South America; thus the involvement of environmental factors is indicated. The incidence increases in Japanese women immigrating to the US. The frequent involvement of both ovaries, especially around menopause, suggests the role of an endocrine factor. Recent epidemiological studies have failed to demonstrate any relationship between ovarian carcinoma and either parity, abortion, or breast-feeding habits. No relationship has been found between ovarian carcinoma and exogenous hormone supply. The incidence is higher among single women and among members of the higher socioeconomic

strata, as well as among women with blood type A. The hazard of tumor induction by ionizing radiation appears to be negligible. Occupational exposure to asbestos and talc can be considered possible causes of ovarian carcinoma. The high frequency noted for the development of ovarian carcinoma subsequent to the onset of breast carcinoma suggests common or similar etiological factors. The mortality ranges from 1.7/100,000/yr in Japan to 11.1/100,000/yr in Denmark. (12 refs)

79-6124 Clinical Aspects of Endometrial Carcinoma. (Ger) Haldemann, R. (Universitäts-Frauenklinik, Schanze-neckstrasse 1, CH-3012 Bern, Switzerland). *Ther Umsch* 36(6): 506-510; 1979.

The incidence, epidemiology, and diagnosis of endometrial carcinoma (ENC) are reviewed. Conditions associated with increased risk of ENC include hypertension, diabetes mellitus, obesity, late menopause, menstrual disorders, and sterility. A disturbance of estrogen metabolism appears to underlie several of these risk factors. About 85% of ENC cases are found in postmenopausal women. An av age at diagnosis of 62 yr has been reported. Moderate obesity results in a risk factor (RKF) of 3, and RKF's as high as 9 have been found for extreme obesity. Histories of menstrual disturbances associated with overproduction of estrogen are reported by most patients, and a retrospective study indicated that about 80% have a glandular-cystic or adenomatous hyperplasia that can be considered a forerunner of ENC. Increased incidence of ENC is associated with increased socioeconomic status. The main symptoms of ENC are menstrual disturbance in premenopausal women and uterine bleeding in older women; the latter becomes more strongly associated with ENC as the time from onset of menopause increases. Women with any of these risk factors as well as those who have taken estrogens for a long period of time should be screened for ENC at regular intervals. (14 refs)

79-6125 Malignant Tumors of the Vulva and Vagina. (Ger) Almendral, A. C. (Universitäts-Frauenklinik, Kantonsspital Basel, CH-4031 Basel, Switzerland); Torhorst, J. *Ther Umsch* 36(6): 538-545; 1979.

The literature concerning malignant tumors of the vulva and vagina is reviewed. Ninety-five percent of all malignant tumors of the vulva are primary, although metastases from primary endometrial, large intestinal, and uterine cervical carcinomas and from renal cell carcinoma, chorio-epithelioma, and vaginal tumors have been encountered. Squamous epithelial carcinoma accounts for 85% of all tumors of the vulva, malignant melanoma for 5%, basal cell carcinoma for 1%, and sarcoma for 2%. Vulval carcinoma develops mostly in the menopause; the av age of the patients is 65 yr, and the median age is 60 yr. The incidence is increased in single and nulliparous women. Chronic and nonspecific infections can be considered to be predisposing factors. Relationships between vulval carcinoma and syphilis, chronic granulomatosis, vulvitis, lymphogranuloma venereum, and condyloma acuminatum apparently exist. Herpes simplex virus type 2 may play an etiological role in vulval carcinoma. Invasive carcinoma is believed to develop from preexisting epithelial atypia. Malignant vaginal tumors account for 1.5-2% of all malignant tumors of the female genitalia. Squamous epithelial carcinoma accounts for about 93%, adenocarcinoma for 4%, and sarcoma for 1.6% of all primary vaginal tumors. The incidence of metastatic tumors, originating from tumors of the ovaries, uterus, vulva, rectum, and urinary bladder, is about twice as high as that of primary malignant tumors. The etiology of squamous epithelial carcinoma

is unknown, but the epidemiological factors involved may be similar to those in vulval carcinoma. The av age of patients with malignant vaginal tumors is 60 yr. Sarcoma botryoides occur mostly in children, while adenocarcinoma occurs mostly in young women after intrauterine exposure to diethylstilbestrol. (23 refs)

79-6126 Smoking and Health. (Ger) Grosser, P. J. (Hygiene-Institut des Bereichs Medizin (Charite), Humboldt-Universitat zu Berlin, Otto-Grotewohl-Strasse 1, DDR-108 Berlin, E. Germany). *Dtsch Gesundheitswes* 34(31): 1478-1481; 1979.

The physiological effects of smoking and its effect on life expectancy and incidence of disease (eg, chronic bronchitis, emphysema, cancer) are reviewed and discussed. Increased incidences of cancer of the larynx, oral cavity, esophagus, urinary bladder, kidneys, and pancreas are associated with the use of tobacco, in addition to the well-established increase in lung cancer incidence. (1 ref)

79-6127 The Epidemiology of Burkitt's Lymphoma: Evidence for a Causal Association with Epstein-Barr Virus. (Eng) de-The, G. (Centre National de le Recherche Scientifique, Univ. Lyon, Faculty Medicine Alexis Carrel, Lyon, France). *Epidemiol Rev (Baltimore)* 1: 32-54; 1979.

Epidemiologic evidence for an etiologic association between Epstein-Barr virus (EBV) and Burkitt's lymphoma (BL) is reviewed. The incidence of BL in Africa varies with altitude, av rainfall, av temperature, age, and sex, and shows some seasonal variation. An international research team in Uganda has established a causal association between high antibody titers to EBV and the risk of developing BL. Together with previous findings, these data indicate that EBV, under extreme conditions, has an oncogenic potential in humans. BL also seems to occur much more frequently in areas where malaria is endemic. A third factor, the presence of chromosomal anomalies, has been associated with the occurrence of BL as well as non-Burkitt's lymphomas. The origin of these chromosomal anomalies has not been determined. (94 refs)

CHEMICAL CARCINOGENESIS

- 79-6128 A Simple Theoretical Criterion of Chemical Carcinogenicity? (Eng) Herrmann, E. C. (Res. Lab., Schering AG, Mullerstrasse 178, D-1000 Berlin 65, W. Germany). *Experientia* 35(9): 1263-1264; 1979.

The simple theoretical criterion for chemical carcinogenicity based on the "average quasi-valence number" is discussed. Since the equation upon which this concept is based depends solely on the molecular formula, it suggests that all isomers of a given organic compound must have the same carcinogenic potential, which is not true. The possibility that carcinogenic metabolites may be formed from a given compound is also overlooked, as it is claimed that it is sufficient to inspect only the parent compound for carcinogenicity. There are also serious logical shortcomings inherent in this criterion. It has been suggested that as an additional necessary criterion for carcinogenicity, the existence of at least one UV-absorption peak in the "purely empirical" range of 206-248 nm must be demonstrated. However, it would be difficult in practice to predict the carcinogenicity of organic molecules by this improved method at a better than 1:1 chance. There are far better theoretical and experimental methods reported in the literature for identifying carcinogenic compounds. (7 refs)

- 79-6129 Serum-induced Chromosome Damage and Neoplastic Transformation of Mouse Cells In Vitro. (Eng) Sanford, K. K. (Lab. Cellular and Molecular Biology, NC1, Bethesda, MD 20014); Parshad, R.; Handelman, S. L.; Price, F. M.; Gantt, R. R.; Evans, V. J. *In Vitro* 15(7): 488-496; 1979.

Cells derived from C3H₁/HeN mouse embryos were grown in medium NCTC-135 supplemented with various combinations of large- and small-molecule fractions of horse serum (HS) and fetal bovine serum (FBS) in an effort to determine whether the small-molecule fraction of HS reproducibly accelerates neoplastic transformation and chromosomal damage, and whether the large-molecule fraction of FBS or of more serum prevents transformation and karyotypic alteration. In addition, an attempt was made to correlate cytologic changes with malignant transformation as tested by growth of cells as sarcomas in vivo. The large-molecule fraction of HS (mare or stallion) produced alterations in chromosome number and structure. HS also caused chromatid breaks and exchanges at or near the centromere; this is in contrast to fluorescent-light-induced breaks, which occur randomly along the chromatid. Efforts to control completely chromosome stability and malignant transformation through the use of large- and small-molecule fractions of HS and FBS or combinations thereof were unsuccessful. The results of in vivo assays indicated that the occurrence of neoplastic transformation cannot be correlated with any one serum fraction or combinations. Using a direct sampling method based on previously described cytologic criteria, diagnosis of malignant transformation was made in 11 cell lines; with one exception, the diagnoses were consistent with results of in vivo assays. - 79-6130 Evaluation of Feasibility of Mutagenic Testing of Shale Oil Products and Effluents. (Eng) Epler, J. L.

(Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Rao, T. K.; Guerin, M. R. *Environ Health Perspect* 30: 179-184; 1979.

The Ames *Salmonella* histidine-reversion system was used to assay the mutagenic potential of crude shale oil, natural crude oil, and the product water from a shale oil process. Metabolic activation was provided with the use of liver homogenates from Aroclor 1254-induced rats. Preliminary results implicate chemicals occurring in the basic (ether-soluble) and neutral fractions as potential genetic hazards. Chemical constituents of these fractions (identified or predicted) were tested individually for mutagenicity, and the results were correlated with those of genetic monitoring. (17 refs)

- 79-6131 Chlorophyll: The Active Factor in Wheat Sprout Extract Inhibiting the Metabolic Activation of Carcinogens In Vitro. (Eng) Lai, C. N. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Nutr Cancer* 1(3): 19-21; 1979.

The active factor in wheat sprout extract that inhibits the metabolic activation of carcinogens in vitro was studied. The inhibitory activities of wheat sprout extracts were directly correlated with chlorophyll levels. Root extract exhibited the same activity as leaf extract when compared at the same chlorophyll level. Chlorophyllin and chlorophyll extracted from wheat sprout chloroplasts did not affect the viability of cells in minimal glucose or nutrient agar plates. In liquid incubation, chlorophyllin reduced the growth of *Salmonella typhimurium* strain TA100 by half at a concentration of 0.6 mg/ml. Chlorophyll reduced the toxicity of several carcinogens, especially those not requiring liver S9 mix activation. Vitamin E and carotene showed little activity in the bacterial mutagenesis test. The potential of chlorophyll as a non-toxic chemopreventive agent appears promising. (8 refs)

- 79-6132 Arsenically Associated Cutaneous Squamous Cell Carcinoma with Hypercalcemia. (Eng) Southwick, G. J. (Dept. Head and Neck Surgery, Roswell Park Memorial Inst., Buffalo, NY); Schwartz, R. A. *J Surg Oncol* 12(2): 115-118; 1979.

The occurrence of an extensive squamous cell carcinoma complicated by hypercalcemia in a 62-yr-old white man who had been treated with 1% potassium arsenite for several years for psoriasis is reported. Steroid therapy had resulted in genital atrophy and bilateral cataract formation. Biopsy of an extensive ulcerative lesion of the right groin revealed well differentiated squamous cell carcinoma. Culture of material from the lesion revealed *Pseudomonas aeruginosa* and *Staphylococcus aureus*. Two wk after hospitalization, the patient developed hypercalcemia (serum calcium, 14.2%), and he died 32 days after admission. Postmortem examination confirmed extensive squamous cell carcinoma of the right groin with local iliac bone invasion and lung metastasis. Extensive bilateral pulmonary atelectasis was also found. (5 refs)

- 79-6133 Asbestos-associated Neoplasms of B Cell Lineage. (Eng) Kagan, E. (Dept. Pathology, Georgetown Univ. Schs. Medicine and Dentistry, 3900 Reservoir Road, N. W., Washington, DC 20007); Jacobson, R. J.; Yeung, K. Y.; Haidak, D. J.; Nachnani, G. H. *Am J Med* 67(2): 325-330; 1979.

Three different asbestos-associated neoplasms of B-cell lineage, chronic lymphocytic leukemia, IgA myeloma, and IgG myeloma, were detected in three men (aged 54, 61, and 71 yr) who had heavy occupational exposure to asbestos dust. Two of the patients had coexistent pulmonary asbestosis, whereas the third patient had a pleural mesothelioma subsequent to his initial presentation with myeloma. Defective cell-mediated immunity and hyperactivity of B-cell function have previously been noted in patients with asbestosis. These asbestos-related immunologic derangements may predispose to the development of immunoproliferative and lymphoproliferative neoplasms, since these tumors have been observed in a variety of other settings characterized by protracted hyperactivity of the immune system. (27 refs)

- 79-6134 Binding of Beryllium to Nuclear Acidic Proteins. (Eng) Parker, V. H. (Molecular Toxicology Section, MRC Toxicology Unit, Medical Res. Council Labs., Woodmansterne Road, Carshalton, Surrey SM5 4EF, England); Stevens, C. *Chem Biol Interact* 26(2): 167-177; 1979.

To gain insight into the mechanism of beryllium toxicity, the in vitro binding of Be to rat liver nuclei was reassessed [$K_{As} = 2.0 \times 10^6$ M: n (binding sites) = 17 nanomoles(nmol) Be/mg protein]. Be also binds to rat liver nucleoli (K_{As} approx 4×10^6 M: $n = 10$ nmol Be/mg protein). Examination of rat liver chromatin fractionated on a hydroxyapatite column shows that Be does not bind to histone or to the nonhistone protein eluted by 0.05 M sodium phosphate. Be is strongly bound to the nonhistone proteins eluted by 0.2 M sodium phosphate ($K_{As} = 1.1 \times 10^6$ M: $n = 55$ nmol Be/mg protein) and, to the same extent, to the fraction containing DNA that is subsequently eluted from the column. Evidence is provided that the latter binding is not due to DNA. The fractions containing the Be-binding proteins also contain the proteins that are phosphorylated to the greater extent. (28 refs)

- 79-6135 Mutagenic Effects of Cadmium on Mammalian Oocyte Chromosomes. (Eng) Watanabe, T. (Dept. Hygiene and Preventive Medicine, Yamagata Univ. Sch. Medicine, Yamagata 990-23, Japan); Shimada, T.; Endo, A. *Mutat Res* 67(4): 349-356; 1979.

The mutagenic effects of cadmium chloride (1.0, 2.0, or 4.0 mg/kg, sc 5 hr before ovulation) on the metaphase-II oocyte chromosomes of virgin female golden hamsters were studied. No structural anomalies were observed, but the frequencies of hyperhaploidy and diploidy increased in the cadmium-treated hamsters, especially those given the higher doses. There were seven anaphase-I oocytes among the 536 oocytes examined. In one of these oocytes, one haploid set had 21 chromosomes and the other set had 23. Most of the increases in numerical anomalies were significant when compared with the results from control hamsters. No specific groups of chromosomes were affected. Oogenesis in the hamster appears to be much more sensitive to cadmium-induced chromosomal anomalies than does the same stage in the mouse. Severe and diffuse hemorrhage was observed on the ovaries of all hamsters given 2.0 or 4.0 mg/kg cadmium. Twelve hours after cadmium administration, 1.8, 2.3, and 3.7 $\mu\text{g/g}$ cad-

mium was found in the ovaries of the hamsters given 1.0, and 2.0, and 4.0 mg/kg cadmium chloride, respectively. Chromosome analysis of metaphase-II oocytes seems to be a useful method for screening the mutagenicity of environmental contaminants in mammalian germ cells in vivo. (31 refs)

- 79-6136 Cytotoxic and Clastogenic Effects of Soluble Chromium Compounds on Mammalian Cell Cultures. (Eng) Levis, A. G. (Inst. Animal Biology, Univ. Padua, Padua, Italy); Majone, F. *Br J Cancer* 40(4): 523-533; 1979.

Cell growth inhibition, reduction in cell survival and the induction of chromosome aberrations and sister chromatid exchange (SCE) were determined in cultured BHK and CHO hamster cell lines treated with 11 water-soluble hexavalent and trivalent chromium compounds. All Cr^{6+} compounds inhibited growth of BHK cells and reduced survival of CHO cells to levels comparable to those obtained only after exposure to Cr^{3+} concentrations 100- to 1,000-fold greater. The cytotoxicity curves obtained with the different Cr^{6+} compounds were almost overlapping, whereas marked differences of activity were found among Cr^{3+} compounds. Giant cells obtained after exposure to Cr^{6+} and Cr^{3+} compounds, as shown by the rise of DNA and RNA per cell, were due to the blockage of the cell cycle without sudden inhibition of macromolecular syntheses. While both Cr^{6+} and Cr^{3+} compounds were able to induce chromosome aberrations, only Cr^{6+} was active in inducing SCE, Cr^{3+} being absolutely incapable of doing so. The frequency of chromosome aberrations was increased about 10-fold after exposure to 1.0 $\mu\text{g/ml}$ Cr^{6+} , but only doubled after treatment with up to 150 $\mu\text{g/ml}$ Cr^{3+} . In spite of the sensitivity of CHO cells to the induction of SCE by mitomycin C, the frequency of SCE hardly doubled after exposure to Cr^{6+} compounds. The present data confirm that Cr^{6+} compounds are characterized by a marked cytotoxicity and clastogenic action on mammalian cell cultures and show that Cr^{3+} compounds, though cytotoxic only at extremely high concentrations and unable to increase the frequency of SCE, are not completely without cytogenetic effect. (35 refs)

- 79-6137 DNA Damage and DNA Repair in Cultured Human Cells Exposed to Chromate. (Eng) Whiting, R. F. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Centre, 601 West 10th Ave, Vancouver V5Z 1L3, Canada); Stich, H. F.; Koropatnick, D. J. *Chem Biol Interact* 26(3): 267-280; 1979.

DNA damage and DNA repair have been observed in cultured human skin fibroblasts exposed to potassium chromate but not to a chromic glycine complex. DNA repair synthesis (unscheduled incorporation of [^3H]thymidine) measured in cells during or following exposure to chromate was significant for chromate concentrations above 10^{-6} M. Maximal DNA repair was observed at about 10^{-4} M chromate; DNA repair capacity was saturated at this concentration. Chromate was stable for at least 8 hr in culture medium and produced approx a linear increase in repair with duration of exposure. DNA damage as determined by alkaline sucrose gradient sedimentation was detected after treatment for 1.5 hr with 5×10^{-4} M chromate. Exposure to 10^{-7} M chromate solution for 7 days inhibited colony formation while acute (1 hr) treatment was toxic at 5×10^{-6} M. The chromic glycine complex was toxic above 10^{-3} M for a 1-wk exposure but was not observably toxic after a 1-hr treatment. These results indicate that chromate rather than chromic compounds may be the carcinogenic form of the metal in humans. The nature of the ultimate carcinogen is discussed. (17 refs)

- 79-6138 Sister Chromatid Exchanges Induced in Cultured Mammalian Cells by Chromate. (Eng) Macrae, W. D. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Center 601, W. 10th Ave., Vancouver V5Z 1L3, British Columbia, Canada); Whiting, R. F.; Stich, H. F. *Chem Biol Interact* 26(3): 281-286; 1979.

The ability of chromate compounds to induce sister chromatid exchanges (SCEs) and chromosome aberrations in human fibroblasts and Chinese hamster ovary (CHO) cells was studied. Chromate compounds at low concentrations induced SCEs and chromosome aberrations in cultured human cells and SCEs in CHO cells. SCE frequency was increased about fourfold over the spontaneous level in human fibroblasts exposed to 10^{-6} M $K_2Cr_2O_7$ or K_2CrO_4 for 48 hr. Chromosome aberrations (primarily chromatid breaks) were also produced in human cells exposed to K_2CrO_4 at concentrations between 8×10^{-7} and 3×10^{-6} M. K_2CrO_4 , but not the trivalent compound $CrCl_3$, induced SCEs in CHO cells at the concentrations tested (10^{-7} - 10^{-5} M); the max SCE level represented a threefold increase over the spontaneous level. The results support the view that chromate compounds may possess mutagenic or carcinogenic activity. (12 refs)

- 79-6139 Establishment of Photoaffinity Label Derivatives of Fluorene as Probes in Studies of Chemical Carcinogenesis in Mammalian Cell Culture. (Eng) Sarraf, A. M. (PO Box 191, Dept. Pharmacology, Univ. Alabama in Birmingham Medical Center, Birmingham, AL 35294); White, W. E.; DiVito, N. *Cancer Res* 39(10): 3903-3908; 1979.

The ability of several bifunctional azidofluorenes (photosensitive analogs of the carcinogen 2-acetylaminofluorene) to transform mouse embryo C3H 10T1/2 cells under conditions of photolysis in situ was studied. Under the conditions studied, UV light was neither toxic nor transforming. The cytotoxic effects of 2,5-diazidofluorene (2,5-DAzF), 2,7-diazidofluorene (2,7-DAzF), and 2-azidofluorene (2-AzF) were identical when the cells were incubated with the drugs in the dark or when the drugs were irradiated in phosphate-buffered saline (PBS) and then added to the cells. When the drugs were added to the cells and then irradiated for ≥ 15 min in complete medium (CM), the cytotoxicities of 2,5-DAzF and 2,7-DAzF were severalfold higher than those of 2-AzF and 7-bromo-2-azidofluorene. The transformation frequency obtained with $1 \mu\text{g/ml}$ 2,5-DAzF or 2,7-DAzF in CM was 4.8 transformed foci/1,000 surviving cells. At $2 \mu\text{g/ml}$, UV irradiation in CM for 15 sec led to transformation by both drugs. 2-DAzF appeared to exert no action on the effect of UV. Preirradiated azidofluorene derivatives were only very weakly transforming for 10T1/2 cells, forming only type II foci. (23 refs)

- 79-6140 Chromosome Breaking Activity of Human Feces and Its Enhancement by Transition Metals. (Eng) Stich, H. F. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Centre, 601 W. 10th Avenue, Vancouver, B.C., V5Z 1L3, Canada); Kuhnlein, U. *Int J Cancer* 24(3): 284-287; 1979.

Chloroform-methanol extracts of feces collected from three apparently healthy persons were tested for their ability to induce chromosome aberrations in cultured Chinese hamster ovary (CHO) cells. The CHO cells were exposed for 3 hr under aerobic conditions to fecal extract diluted in the range 1:10 to 1:320 in culture medium. The frequency of plates with well-defined chromosome aberrations, including breaks, acentric fragments,

and exchanges, significantly increased following exposure to the fecal extracts. The addition of manganese (Mn^{2+} ; 10^{-4} M) and, to a lesser degree, of copper (Cu^{2+} ; 10^{-5} M) stimulated the induction of chromosome aberrations, while iron (Fe^{2+} and Fe^{3+} ; both 10^{-4} M) inhibited it. The effects on mitotic inhibition were similar. The addition of catalase to the fecal extract or to the mixture of fecal extract and Mn^{2+} abolished the mitotic inhibition and greatly reduced the frequency of chromosome aberrations. It is suggested that the capacity of fecal extracts to induce chromosome aberrations might play a role in the etiology of colon cancer. (17 refs)

- 79-6141 Enhancement by Transition Metals of Unscheduled DNA Synthesis Induced by Isoniazid and Related Hydrazines in Cultured Normal and Xeroderma Pigmentosum Human Cells. (Eng) Whiting, R. F. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Centre, Vancouver, B. C., Canada); Wei, L.; Stich, H. F. *Mutat Res* 62(3): 505-515; 1979.

In combination with the transition metals $Mn(II)$, $Cu(II)$, and $Fe(III)$, isoniazid and related hydrazine compounds induced unscheduled DNA synthesis (DNA repair) in cultured human fibroblasts. Manganese at 10^{-5} and 10^{-4} M strongly enhanced DNA repair induced by isoniazid, iproniazid, nialamide, and hydrazine. Peak levels of DNA repair occurred at 5×10^{-4} - 10^{-3} M of the four hydrazine compounds. Copper caused less enhancement of DNA repair, while iron had no detectable effect. Without added metal, unscheduled DNA synthesis was not observed in cells treated with any of the freshly-prepared hydrazine compounds. However, following preincubation in medium for 6-12 hr, isoniazid alone at high concentrations (10^{-2} - 10^{-1} M) induced DNA repair. With isoniazid/manganese mixtures, preincubation did not further enhance DNA repair except at low concentrations of isoniazid (2.5×10^{-4} M). Catalase reduced the DNA damage caused by preincubated isoniazid and by the isoniazid/metal mixtures. Exposure of repair-deficient xeroderma pigmentosum cells to isoniazid plus manganese resulted in a DNA-repair profile similar to that of normal cells. The results are consistent with the assumption that hydrogen peroxide is a critical intermediate for the production of free radicals that cause the observed DNA damage. (24 refs)

- 79-6142 Fate of Nickel Subsulfide During Carcinogenesis Studied by Autoradiography and X-Ray Powder Diffraction. (Eng) Oskarsson, A. (Dept. Toxicology, Univ. Uppsala, Uppsala, Sweden); Andersson, Y.; Tjalve, H. *Cancer Res* 39(10): 4175-4182; 1979.

Sarcomas were induced in mice by the im and sc administration of ^{63}Ni - and ^{35}S -labeled nickel subsulfide, and the fate of the Ni_3S_2 during carcinogenesis was studied. Whole-body autoradiography showed a gradual loss of solubilized ^{63}Ni and ^{35}S radioactivity from the injection site. There was also a loss of nonsolubilized dust particles, which appeared to be phagocytized by reticuloendothelial cells in the liver, spleen, and regional lymph nodes. Microautoradiography showed that the radioactivity within both the $^{63}Ni_3S_2$ - and the $Ni_3^{35}S_2$ -induced tumors was associated almost exclusively with dust particles. There was no specific or excessive localization of solubilized radioactivity in the tumors or in metastases. Two patterns of localization of dust particles within the tumors were observed: one with particles concentrated in a central part of the tumor and one with the particles present in the periphery of the tumor. X-ray powder diffraction of the insoluble crystalline material in the tumors indicated that conversion of αNi_3S_2 to αNi_7S_6 and βNiS had occurred. (20 refs)

- 79-6143 Mutagenic Activity of Anticancer Agent *cis*-Dichlorodiammine Platinum-II. (Eng) Wiencke, J. K. (Dept. Environmental Health, Univ. Minnesota, Sch. Public Health, Minneapolis, MN 55455); Cervenka, J.; Paulus, H. *Mutat Res* 68(1): 69-77; 1979.

cis-Dichlorodiamminoplatinum-II (*cis*-DDP) has been widely used as an anticancer chemotherapeutic agent. The mutagenicity of *cis*-DDP was investigated in vitro and in vivo by measuring sister-chromatid exchange (SCE) and chromosomal aberrations. Parallel human lymphocyte cultures were incubated with and without the addition of bromodeoxyuridine (BrdU) at four concentrations of *cis*-DDP [0.25, 0.50, 0.75, and 1.00 μ g/ml]. Significant increases in SCE rate were observed at 0.25 μ g/ml and higher, showing a clear dose response relationship between SCE rate and *cis*-DDP concentration. A significant increase in chromosome breakage and tetradial figures was observed in BrdU-free cultures treated with *cis*-DDP, again showing a dose dependency. Analysis of the distribution of cells in the first, second and third division in *cis*-DDP-treated cultures demonstrated that the drug depressed mitotic activity. In vivo analysis of SCE and chromosome aberrations in mice showed that 13.85 mg/kg ip of *cis*-DDP produced significant increases in the rate of SCE and chromosome aberrations in bone-marrow cells. (34 refs)

- 79-6144 In Vivo Conversion of Sodium Azide to a Stable Mutagenic Metabolite in *Salmonella typhimurium*. (Eng) Owais, W. M. (Program in Genetics, Washington State Univ., Pullman, WA 99164); Kleinhofs, A.; Nilan, R. A. *Mutat Res* 68(1): 15-22; 1979.

Salmonella typhimurium strains TA1530 and G46 growing in the presence of 5×10^{-4} M sodium azide produced a mutagenic metabolite, most of which was found in the growth medium. The metabolite was highly mutagenic in the base-substitution strains TA1530 and TA1535 but not in the frameshift mutants TA1537 and TA1538. Metabolite production in TA1530 occurred in the log phase of bacterial growth between 2-12 hr in the growth cycle. In G46, metabolite production also occurred in log phase between 2-8 hr in the growing cycle. Unlike azide, the metabolite induced mutations in resting TA1530 strain cells at pH 6 and 9. Neither the metabolite nor azide reverted resting cells of the G46 strain. The ability of cells to produce a mutagenic metabolite from azide may represent a new dangerous aspect of environmental mutagenesis. (28 refs)

- 79-6145 Simultaneous Staining of Sister Chromatid Exchanges and Q-Bands in Human Chromosomes After Treatment with Methyl Methane Sulphonate, Quinacrine Mustard, and Quinacrine. (Eng) Haglund, U. (Dept. Medical Cell Genetics, Medical Nobel Inst., Karolinska Institutet, S-10401 Stockholm 60, Sweden); Zech, L. *Hum Genet* 49(3): 307-317; 1979.

A method for staining bromodeoxyuridine (BrdU)-treated human peripheral blood lymphocytes using only quinacrine mustard (QM) was developed, and sister-chromatid exchanges (SCE's) and the Q-banding patterns of the stained cells were examined. The number of SCE's per chromosome was in good agreement with the Poisson distribution. In all but one group of cells treated with methyl methanesulfonate (MMS), QM, or quinacrine (Q), there was an increase in SCE frequency ($p < 0.01$). The longer chromosomes (A-C) tended to show more SCE's than expected, and the short ones (D-G) tended to show fewer than expected. When groups treated

with QM and Q, respectively, were pooled, a significant difference was found between long and short chromosomes in SCE frequency compared with that in MMS-treated cells. The greatest proportion of SCE's (76%) was located on the pale chromosome bands; 13% were located on the intense Q bands, and 11% were located at junction areas. None of the chemicals used altered the pattern of occurrence of SCE's. In a number of cases, SCE's appeared to occur at identical sites in homologous chromosomes. The number of SCE's occurring at identical sites exceeded the number expected ($p < 0.001$). Only a few structural aberrations were found, and there were fewer in the treated cells than in the untreated control cells. (24 refs)

- 79-6146 Mutagenicity of the Naturally Occurring Carcinogen Cycasin and Synthetic Methylazoxymethanol Conjugates in *Salmonella typhimurium*. (Eng) Matsushima, T. (Dept. Molecular Oncology, Inst. Medical Science, Univ. Tokyo, Shirokane-dai, Minato-ku, Tokyo 108, Japan); Matsumoto, H.; Shirai, A.; Sawamura, M.; Sugimura, T. *Cancer Res* 39(9): 3780-3782; 1979.

The mutagenicity of cycasin was demonstrated in a modification of the Ames *Salmonella* test in which the compound was preincubated with β -glucosidase and the tester strain in liquid medium. The mutagenicity of cycasin to six histidine-dependent *Salmonella* strains varied considerably, with strain HisG46 being the most susceptible. Methylazoxymethyl- β -D-glucosiduronic acid, which also has been considered nonmutagenic, similarly became mutagenic when preincubated with β -glucuronidase. Methylazoxymethyl acetate, which is slightly mutagenic in the Ames standard pour plate assay, became highly mutagenic upon preincubation. The mutagenicity of free methylazoxymethanol was confirmed, and a linear dose-response relationship was observed. The common conditions required for the activation of nonmutagenic methylazoxymethanol conjugates, cycasin, and methylazoxymethyl- β -D-glucosiduronic acid are a 90-min preincubation at 30 C, pH 6.5, with an appropriate hydrolase and *Salmonella typhimurium* HisG46. (18 refs)

- 79-6147 Methanol Potentiation of Carbon Tetrachloride-induced Hepatotoxicity. (Eng) Cantilena, L. R. (Dept. Pharmacology, Univ. Kansas Medical Center, Coll. Health Sciences and Hosp., Kansas City, KS 66103); Cagen, S. Z.; Klaassen, C. D. *Proc Soc Exp Biol Med* 162(1): 90-95; 1979.

The mechanism by which methanol (M) and other aliphatic alcohols potentiate carbon tetrachloride hepatotoxicity was investigated in Sprague-Dawley rats. M administration (7 ml/kg, po) was followed at various times by CCl_4 administration (0.1 ml/kg, ip). Max potentiation of serum alanine aminotransferase (ALT) by M occurred when CCl_4 was administered 48 hr after M administration. However, all subsequent observations were made 24 hr after M administration, since individual variation was greatest at 48 hr. Pretreatment 24 hr before CCl_4 administration with M or isopropanol (2.5 ml/kg, po), but not ethanol (6 ml/kg, po), elevated plasma ALT activity and hepatic triglyceride levels and decreased hepatic glucose-6-phosphatase activity relative to that in animals receiving only CCl_4 (0.01-0.3 ml/kg, ip). CCl_4 administration alone (0.1 ml/kg, ip) or after M pretreatment did not enhance lipid peroxidation in vivo, as determined by diene conjugation. M Pretreatment did enhance the covalent binding of Cl_4 -labeled CCl_4 to isolated microsomal protein and microsomal lipid. M alone caused significant alterations in hepatic triglyceride and glucose-6-

phosphatase levels but not plasma ALT activity, although the effect of M plus CCl₄ on plasma ALT was greater than the additive. It is concluded that M and isopropanol both potentiate CCl₄ hepatotoxicity by increasing the covalent binding of the compound to microsomal proteins and lipids. (23 refs)

- 79-6148 Metabolism of the Colon Carcinogen Methylazoxymethanol Acetate. (Eng) Zedeck, M. S. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Frank, N.; Wiessler, M. *Front Gastrointest Res* 4: 32-37; 1979.

The metabolism of the colon carcinogen methylazoxymethanol acetate (MAM, 10 ml/kg, ip or iv) by male Sprague-Dawley rats was compared with that of acetoxymethyl-methyl-N-nitrosamine (AMMN) and N-methyl-N-nitrosourea (MNU). The rats were pretreated with pyrazole (180 mg/kg) or disulfiram (1 g/kg). The lethal effects of MAM were potentiated by prior treatment with disulfiram, but blocked by pyrazole pretreatment. The lethal effects of AMMN and MNU were not affected by prior treatment with pyrazole. MAM (10 mg/kg) inhibited thymidine incorporation into DNA by approx 15%, and pretreatment with disulfiram resulted in 65% inhibition. Histologic abnormalities in the colonic epithelium were increased in disulfiram-pretreated animals. Pyrazole pretreatment significantly reduced the MAM-induced inhibition of thymidine incorporation into colonic DNA. Pyrazole also eliminated the histologic abnormalities in the colonic epithelium seen after MAM. The results suggest that the metabolite of MAM responsible for its toxicity is probably the corresponding aldehyde. (11 refs)

- 79-6149 Formation of Carbonyl Chloride in Carbon Tetrachloride Metabolism by Rat Liver In Vitro. (Eng) Shah, H. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA 19140); Hartman, S. P.; Weinhouse, S. *Cancer Res* 39(10): 3942-3947; 1979.

To identify intermediates of carbon tetrachloride metabolism, whole, suitably fortified rat liver homogenates were incubated with ¹⁴CCl₄ in the presence and absence of pools of unlabeled, suspected intermediates. In the presence of NADH or NADPH, incorporation of radioactivity was rapid and substantial in CO₂, lipid, protein, and the acid-soluble fraction. It was not influenced by the presence of large pools of unlabeled chloroform or formate, thus excluding these substances as obligatory intermediates. However, when incubated with L-cysteine, incorporation of radioactivity in the acid-soluble fraction was almost doubled, and about one-third of the radioactivity of this fraction was identified as 2-oxothiazolidine 4-carboxylic acid. Based on current knowledge of CCl₄ metabolism, the following aerobic pathway is proposed: microsomal cleavage to Cl⁻ and ·CCl₃ and oxidation of the latter to the unstable intermediate, Cl₃COH, which loses HCl to yield COCl₂. COCl₂ is likely to be the major source of CO₂ from CCl₄, but is probably not the intermediate that binds to lipid and protein. The addition of glutathione had no effect on CCl₄ metabolism in rat liver homogenate, suggesting that glutathione S-transferases, which catalyze other dehalogenation reactions, do not play a role in CCl₄ metabolism. - 79-6150 Binding of Carcinogenic Halogenated Hydrocarbons to Cell Macromolecules. (Eng) Banerjee, S. (Lab. Organic Chemistry and Carcinogenesis, Inst. Environmental

Medicine, New York Univ. Medical Center, New York, NY 10016); Van Duuren, B. L. *J Natl Cancer Inst* 63(3): 707-711; 1979.

Liver and stomach microsomal preparations obtained from 7- to 10-wk-old B6C3F₁ mice were incubated individually with [¹⁴C]ethylene dibromide (EDB), or [¹⁴C]ethylene dichloride (EDC), salmon sperm DNA, and an NADPH-generating system at 37 C for 60 min. Both EDB and EDC bound to stomach and hepatic microsomal proteins and to salmon sperm DNA. The binding of EDB to protein of denatured stomach microsomes was 4% compared to that obtained with native microsomes. Only 1% of EDB that was bound to hepatic protein in the presence of intact microsomes was bound in the presence of denatured hepatic microsomes. The amount of EDB bound to protein or to DNA increased with greater concentrations of hepatic or gastric microsomes. SKF-525A, an inhibitor of the microsomal metabolism of various substrates, significantly inhibited the binding of EDB to protein and DNA; binding of EDB to hepatic microsomal protein was inhibited by 79%. Glutathione and 1-methyl-2-mercaptoimidazole markedly decreased the binding of EDB, which indicated that a reactive electrophilic intermediate of EDB is involved in the binding. The binding of EDC to liver proteins of (C57BL/6x3H/H3)F₁ mice, which are susceptible to liver tumor induction by EDC and to DNA, was significantly higher than the corresponding binding for Osborne-Mendel rats, a species not susceptible to liver tumor induction by this compound. These results suggest that metabolic activation of EDB and EDC is required for their covalent binding to macromolecules. (26 refs)

- 79-6151 Metabolic Activation of Chlorinated Ethylene Derivatives. (Eng) Henschler, D. (Inst. Toxicology, Univ. Wurzburg, D-8700 Wurzburg, W. Germany); Bonse, G. *Adv Pharmacol Ther* 9: 123-130; 1979.

The chlorinated ethylenes (CE), were studied to determine the structural requirements for their oncogenic effects. The epoxides of all CEs except 1,1-dichloroethylene oxide were prepared, and the in vitro rearrangement mechanisms were studied. The epoxide rearrangement products were either chlorinated aldehydes or acyl chlorides. The metabolites excreted in vivo, chlorinated ethanols and acetic acids, can be derived from these epoxide rearrangement products. Trichloroethylene was an exception; its epoxide rearranged in vitro to dichloroacetyl chloride, whereas the metabolites are oxidation or reduction products, respectively of trichloroacetaldehyde. In vivo, trichloroethylene epoxide is converted, via the trivalent iron of cytochrome P450, at the site of formation in the hydrophobic premise to chloral. In a modified Ames test system using *Escherichia coli* K 12, vinyl chloride, vinylidene chloride, and trichloroethylene exerted mutagenic activity after activation by induced liver microsomes. The tetra- and 1,2-dichloroethylenes (cis and trans) were inactive in this system. A molecular rule derived from these findings states that unsymmetric chlorine substitution induces, by an imbalanced electron withdrawing effect, the epoxides to become highly electrophilic, this being a prerequisite for mutagenicity and carcinogenicity. (18 refs)

- 79-6152 Spontaneous and Induced *rho* Mutants of *Saccharomyces cerevisiae*: Patterns of Loss of Mitochondrial Genetic Markers. (Eng) Heude, M. (Institut Curie-Biologie, Centre Universitaire, 91405 Orsay, France); Fukuhara, H.; Moustacchi, E. *J Bacteriol* 139(2): 460-467; 1979.

Fifteen mitochondrial genetic markers were examined in independent spontaneous *rho* mutants of *Saccharomyces cerevisiae* to determine whether any specific pattern of deletion could be observed. Among the 597 isolated *rho* clones in which the genotype was completely determined, only 2.5% retained the 15 markers; 6.2% lost all of the markers, and 7.4% were multiple deletions. The segment *oxi3-phol/O(II)-mit175*, alone or in association with other markers, was included in numerous types of deletions. When the loss frequency of each marker was plotted as a function of its position on the gene map, a progressive decline appeared on each side of the preferentially lost region, *oxi3-phol/O(II)-mit175*. Previously reported data concerning 3-carbethoxypsoralen- and ethidium bromide-induced *rho* mutants were compared with the pattern of spontaneous *rho* mutants; the sensitive region was the same in both cases. The regions flanking the sensitive region were lost much less often in induced than in spontaneous *rho* mutants, indicating a special sensitivity of the *oxi3-phol/O(II)-mit175* region to mutagenic agents. These results suggest that the basic mechanism of *rho* induction is the same in spontaneous and induced mutagenesis. (28 refs)

- 79-6153 Tumors in Male Rats Fed Ethyl Chlorophenoxyisobutyrate, a Hypolipidemic Drug. (Eng) Svoboda, D. J. (Dept. Pathology, Univ. Kansas, Coll. Health Sciences and Hosp., Kansas City, KS 66103); Azarnoff, D. L. *Cancer Res* 39(9): 3419-3428; 1979.

The tumorigenicity of the hypolipidemic drug clofibrate (ethyl chlorophenoxyisobutyrate, Atromid-S) was determined in male F344 rats. The drug was fed at a concentration of 0.5% in the diet of 25 rats for 72-97 wk, and the animals were inspected for tumors up to a max of 129 wk. Between 72 and 129 wk, there were 10 rats with a total of 16 tumors. These included four hepatocellular carcinomas, an adenocarcinoma of the glandular stomach, a papillary carcinoma of the urinary bladder, an acinar cell carcinoma of the pancreas, a lymphosarcoma involving the pancreas, acinar cell adenomas of the pancreas, a renal carcinoma, and sarcomas of the lung and parotid gland. Although the number of experimental animals was small, none of these tumors were present in 25 controls, and systematic examination of available literature dealing with spontaneous tumors in several thousand rats indicated that the tumors in clofibrate-fed rats were not spontaneous. Several of the tumors were transplanted through several generations. Clofibrate, like two other hypolipidemic drugs that are carcinogenic, causes peroxisome proliferation. It is speculated that some drugs that cause peroxisome proliferation may represent a new class of chemical carcinogens and that there may be a relationship between peroxisome proliferation and malignant transformation. (60 refs)

- 79-6154 Tumorigenicity of the Hypolipidaemic Peroxisome Proliferator Ethyl- α -p-chlorophenoxyisobutyrate (Clofibrate) in Rats. (Eng) Reddy, J. K. (Dept. Pathology, Northwestern Univ. Medical Sch., Chicago, IL); Qureshi, S. A. *Br J Cancer* 40(3): 476-482; 1979.

Ethyl- α -p-chlorophenoxyisobutyrate (clofibrate), a hypolipidemic drug which induces hepatomegaly and peroxisome proliferation in rat and mouse liver cells, was fed to 15 male F344 rats at a dietary concentration of 0.5% for up to 28 mo. Hepatocellular carcinomas developed in 10/11 (91%) rats killed between 24 and 28 mo. Other tumors included two pancreatic carcinomas, a leiomyoma of the small intestine, and a large dermatofibrosar-

coma. Clofibrate is the third hypolipidemic peroxisome proliferator demonstrated to be hepatocarcinogenic in rats. These studies suggest that hypolipidemic agents which are capable of producing a sustained hepatomegaly and peroxisome-proliferative effect may also induce liver tumors. (29 refs)

- 79-6155 Application of Clofibrate in the 70s. Epidemiological Aspects. (Swe) Bergstrom, I. (Ostersund, Sweden); Boethius, G.; Rydstrom, P. O. *Lakartidningen* 76(28/29): 2538-2539; 1979.

One hundred and twenty-five persons (63 men and 62 women, aged >30 yr) for whom clofibrate was prescribed were followed up for possible side effects in an epidemiological study. Four patients (all women) developed malignant diseases during the observation period. In two of these patients, malignant diseases (not specified) were diagnosed 5 yr after the prescription of 100 and 200 capsules of Atromidin, respectively. Another patient developed breast cancer 1 yr after clofibrate treatment (3 prescriptions), and ovarian cancer was found in the fourth woman about 3 yr after 2 yr of clofibrate treatment. In view of the small number of the patients involved, it is impossible to evaluate the possible increase in cancer risk following clofibrate treatment. (5 refs)

- 79-6156 Effect of Carcinogen Ethionine on Enzymatic Methylation of DNA Sequences with Various Degrees of Repetitiveness. (Eng) Boehm, T. L. (Zentrum der Biologischen Chemie der Universitat Frankfurt am Main, Theodor-Stern Kai 7, D-6000 Frankfurt am Main 70, W. Germany); Drahovsky, D. *Eur J Cancer* 15(9): 1167-1173; 1979.

The effect of ethionine on the pattern of enzymatic DNA methylation in sequences of various functions and degrees of repetitiveness was studied in P815 mastocytoma cells. The cells were labeled simultaneously with [14 C]deoxycytidine and L-[methyl- 3 H]methionine. After 48 hr, DNA was isolated by repeated ribonuclease and pronase treatment and sonicated to a fragment length of about 450 base pairs. Separation of inverted (ABC...CBA) and ordinary repetitive ABC...ABC...ABC DNA sequences was achieved after heat denaturation and reassociation to $Cot < 0.001$. The individual fractions were hydrolyzed in 96% formic acid, and the DNA bases were separated by paper chromatography. The relative rates of enzymatic DNA methylation were computed and indicated that the inverted repetitive sequences were methylated 50% more than the ordinary repetitive sequences and about 300% more than the intermediary and unique sequences. These methylation rates changed dramatically in cells grown in the presence of ethionine. At an ethionine concentration as low as 0.01 mM, the methylation of inverted repetitive sequences dropped to the level of enzymatic methylation of the ordinary repetitive sequences and remained unchanged up to 0.3 mM. The other sequence classes were also less methylated in cells grown in the presence of ethionine, but the effect was less pronounced. The inverted repetitive sequences might represent acceptor sites for regulatory sites for regulatory protein, and their hypomethylation may be related to the ethionine-induced re-expression of certain genes. (42 refs)

- 79-6157 Metabolic Activation and Deactivation of Mutagens and Carcinogens. (Eng) De Flora, S. (Istituto di Igienologia, Università di Genova, Genoa, Italy). *Ital J Biochem* 28(2): 81-103; 1979.

The in vitro metabolic behavior of 14 mutagens was investigated in the Ames *Salmonella typhimurium* test in the presence and absence of a rat liver microsomal fraction (S-9 mix) and an NADPH-generating system. Dose-response curves were obtained by relating the amounts of mutagenic compounds to the number of TA100 revertants per plate induced in the absence or in the presence of S-9 mix. In the presence of S-9 2-aminofluorene and benzo(a)pyrene were activated, while there was a slight increase in the mutagenicity of 1,2-epoxybutane. Glycidol, folpet (N-trichloromethylthiophthalimide), nitrofurantoin, and 2-nitronaphthalene were all unchanged in the presence of S-9. The activities of 1,1,1-trichloropropene-2,3-oxide, sodium nitrite, sodium nitrites, 5-nitro-2-furoic acid, and captan (N-trichloromethylthiotetrahydrophthalimide) were decreased. Styrene oxide, sodium azide, and sodium dichromate were deactivated as mutagens in the presence of S-9. These metabolic variations of mutagenicity may account for at least a part of the conflicting nature of in vivo and in vitro findings. Some of the so-called false positives in the *Salmonella* test should be envisaged as true mutagens, which can undergo metabolic deactivation processes and yield negative results in animal carcinogenicity tests. These in vitro findings may be useful to explain the epidemiological data and the results of animal tests, and to assess the possible health hazards of mutagens. (40 refs)

- 79-6158 Mutagenicity of Chloroprene, 1-Chloro-1,3-*trans*-Butadiene, 1,4-Dichlorobutene-2 and 1,4-Dichloro-2,3-Epoxybutane in *Drosophila melanogaster*. (Eng) Vogel, E. (Dept. Radiation Genetics and Chemical Mutagenesis, State Univ. Leiden, Wassenaarseweg 72, Leiden, Netherlands). *Mutat Res* 67(4): 377-381; 1979.

The mutagenicity of the following halo-olefins for *Drosophila melanogaster* were studied: 2-chloro-1,3-butadiene (chloroprene), 1-chloro-1,3-butadiene (1-CB), 1,4-dichlorobutene-2 (DCB), and 1,4-dichloro-2,3-epoxybutane (DCEB). Chloroprene increased the percentage of recessive lethals ($P < 0.01$) in the *Basc* test, in which male Berlin K flies were fed the chemicals and mated to virgin females; the effect was not dose-related. A highly purified sample of chloroprene was noncytotoxic, but 40%-60% of treated males died within 66-72 hr after exposure to 11.4 mM of a sample containing several impurities. 1-CB was slightly more mutagenic than chloroprene, and DCB and DCEB proved to be both mutagenic and cytotoxic. These results confirm those obtained in other mutagenicity assay systems. (10 refs)

- 79-6159 Pleiotropic Effects of Ribosomal Mutations for Cycloheximide Resistance in a Double-resistant Homocaryon of *Neurospora crassa*. (Eng) Vomvovanni, V. E. (Dept. Biology, Nuclear Res. Center Democritos, Aghia Paraskevi, Athens, Greece); Argyrakakis, M. P. *J Bacteriol* 139(2): 620-624; 1979.

Pleiotropic effects of two ribosomal mutations for cycloheximide resistance were studied in an *act-2 act-3* double-resistant homocaryon (strain dm6596) of *Neurospora crassa*. Morphologically, the dm6596 strain had a compact and highly branched colony structure compared with the spreading filamentous form of the wild type and the two parental strains. In liquid shake cultures the rate of increase of the mycelial mass of the dm6596 strain was slowed to 50% of the rate of the wild type and the two parental strains; the mycelial front of dm6596 in Ryan tubes proceeded at $\leq 30\%$ of the wild-type rates. After sucrose density gra-

dient centrifugation, the 40S ribosomal subunits appeared to be in excess in dm6596, whereas they were present in a 1:1 ratio in the wild-type strains. Lowering the temperature from 30 C to 25 C resulted in a 70% decrease in the growth rate of dm6596 in Ryan tubes compared with a 20% decrease for the other strains. Growth in liquid media was not cold sensitive. It is suggested that the observed morphological alterations can be imposed by either translational discrimination of altered ribosomes for a given messenger RNA or lack of the ability of a given protein to be properly integrated into a functional unit in cell membranes modified after the attachment of mutated ribosomes. (16 refs)

- 79-6160 Mutagenicity of 1,2-Dicarbonyl Compounds: Maltol, Kojic Acid, Diacetyl and Related Substances. (Eng) Bjeldanes, L. F. (Dept. Nutritional Sciences, Univ. California, Berkeley, CA 94720); Chew, H. *Mutat Res* 67(4): 367-371; 1979.

The mutagenicity of maltol, kojic acid, diacetyl, and related substances in *Salmonella typhimurium* strains TA98 and TA100 was studied. Glyoxal, diacetyl, 1,2-cyclohexanedione, maltol, ethyl maltol, and kojic acid showed dose-related mutagenic activity in strain TA100, but not in strain TA98. S9 liver microsome preparation had little effect on the activity of these compounds. Dimethyl oxalate, pyruvic acid, ninhydrin, 3-methyl-1,2-cyclopentanedione, α -pyrone, chromone-2-carboxylic acid, 1,2-naphthoquinone, dehydroascorbic acid, and catechol had no mutagenic effect on either tester strain in the presence or absence of the S9 mix. 2-Hydroxy-1,4-naphthoquinone (>1 mg/plate) and 1,4-benzoquinone (>5 μ g/plate) were toxic but not mutagenic. Although the mutagenic activities of the environmentally important 1,2-dicarbonyl compounds must be classified as weak, detailed investigations into the genetic toxicology of some of these compounds are warranted. (19 refs)

- 79-6161 Enhancement of Artificial Lung Metastases in Mice Caused by Cyclophosphamide. I. Participation of Impairment of Host Antitumor Resistance. (Eng) Milas, L. (Labs. Immunology, Dept. Physiology, Medical Faculty, Central Inst. Tumors and Allied Diseases, Univ. Zagreb, Ilica 197, 41000 Zagreb, Yugoslavia); Malenica, B.; Allegretti, N. *Cancer Immunol Immunother* 6(3): 191-196; 1979.

The mechanism of cyclophosphamide (CY, 50-250 mg/kg, ip, 1 day before iv inoculation of 10^4 tumor cells)-enhancement of lung metastases was studied using CBA mice and the syngeneic FSa fibrosarcoma. CY markedly enhanced metastasis formation; the number of lung metastases increased with dose up to 180 mg/kg. The highest yield of metastases was obtained when tumor cells were injected 1 day after CY, the yield being almost nil in mice given CY 14 days before tumor inoculation. CY was also effective in increasing metastasis in whole body-irradiated and TIR mice. Its effect, however, was abolished to a great extent by reconstituting mice with nonseparated or nonadherent spleen and bone marrow cells from either normal or TIR mice. Lymphoid cells from CY-treated mice had no such reconstitutive capacity. The data suggest that CY-induced enhancement of tumor metastasis formation was partly due to nonimmunologic factors and partly due to suppression of non-T lymphocytes. (21 refs)

- 79-6162 A Comparison of Lithocholic Acid Metabolism by Intestinal Microflora in Subjects of High- and Low-Risk

Colon Cancer Populations. (Eng) Kelsey, M. I. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Molina, J. E.; Hwang, K. K. *Front Gastrointest Res* 4: 38-50; 1979.

The metabolism of lithocholic acid-3 α -sulfate (LASO₄) by the intestinal microflora of human volunteers consuming high-beef (high risk for contracting colon cancer), low-beef, or vegetarian (low risk for contracting colon cancer) diets was studied. Microflora obtained from an individual on a high-beef diet (HBD) metabolized tauroolithocholate (TL) to 5 β -cholanolic acid, 3-keto-cholanolic acid (3-keto), and a mixture of lithocholic acid (LA) and isolithocholic (ILA) acid. When LA was used as a substrate, the metabolites were ethyl LA, 3-keto, LA, and ILA and its sulfate ester. Metabolites of sulfolithocholic acid (LASO) were 5 β -cholanolic acid, LA, ILA, and an unsaturated derivative, eg, cholenate. The metabolism of LASO₄ by microflora from an individual consuming a low beef diet (LBD) was far less extensive than that by microflora from the individual on the HBD; the substrate was metabolized to an intermediate extent by the microflora from an individual consuming a vegetarian diet (VD). The ability of the donor's microflora to form cholانات/ cholenates from LASO₄ decreased in the order: HBD > VD > LBD. (29 refs)

79-6163 Genetic Effects of Formaldehyde in Yeast. III. Nuclear and Cytoplasmic Mutagenic Effects. (Eng) Chanet, R. (Institut Curie-Biologie, Centre Universitaire, Batiment 110, 91405 Orsay, France); von Borstel, R. C. *Mutat Res* 62(2): 239-253; 1979.

The nuclear mutagenic effects of formaldehyde (FA) in yeast strains having different repair capacities were studied. Low concentrations of FA induced nuclear mutations in yeast cells, the induction of reversions being a linear function of the FA concentration and dependent upon the repair capacities of the treated cells. A strain defective in excision repair (*rad3-12*) was more mutable by FA than was the isogenic wild type, whereas a strain with a block in the mutagenic pathway (*rad6-1*) was not mutable after similar treatment. Allele specificities were found; in particular, the *lys1-1* mutation was not reversible by FA. Higher concentrations of FA efficiently induced the cytoplasmic "petite" mutation under nongrowing conditions in which a lethal effect was observed. The growth phase as well as the physiological state influenced this mutagenic effect. (46 refs)

79-6164 Calcium Dependence of Hormone-stimulated cAMP Accumulation in Intact Glial Tumor Cells. (Eng) Brostrom, M. A. (Dept. Pharmacology, Rutgers Medical Sch., Coll. Medicine and Dentistry of New Jersey, Piscataway, NJ 08854); Brostrom, C. O.; Wolff, D. J. *J Biol Chem* 254(16): 7548-7557; 1979.

The role of calcium ion in the regulation of cyclic AMP (cAMP) synthesis in response to norepinephrine (NE) in intact C6 rat glial tumor cells was studied. The Ca²⁺ content of the C6 cells was reduced approx fivefold after repeated treatment with media containing ethylene glycol bis(β -aminoethyl ether) N,N'-tetraacetic acid (EGTA), but there was no loss of cell viability. The ability of the cells to accumulate cAMP in response to β -adrenergic receptor agonists was reduced 60%-70% following Ca²⁺ depletion. The effects of Ca²⁺ appeared to be exerted on components of the adenylate cyclase system other than the catecholamine receptor.

Micromolar free Ca²⁺ concentrations in the extracellular medium were sufficient to restore a maximal NE response to Ca²⁺-depleted cells. Cells in media containing Ca²⁺ exhibited a characteristic biphasic time course of cAMP accumulation; in Ca²⁺-depleted cells, cAMP accumulated more slowly and the subsequent decline in cAMP concentration was also reduced. Verapamil, an inhibitor of plasmalemmal Ca²⁺ influx, decreased the Ca²⁺-dependent component of cAMP accumulation when added prior to the cation. The effect of Ca²⁺ on cAMP accumulation was reduced more extensively by pretreatment at 45 C under Ca²⁺-depleted (80% loss) than under Ca²⁺-restored (30% loss) conditions. Trifluoperazine (15 μ M) decreased the Ca²⁺-dependent increment in cAMP accumulation in Ca²⁺-restored cells. This inhibition was not overcome by increasing NE or extracellular Ca²⁺ concentrations. (44 refs)

79-6165 Tissue Specificity in Metabolic Activation. (Eng) Bartsch, H. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 69008 Lyon, France); Sabadie, N.; Malaveille, C.; Camus, A. M.; Brun, G. *Adv Pharmacol Ther* 9: 93-102; 1979.

A model for the organospecificity of chemicals is proposed based on data from several systemically acting carcinogens: N-nitrosamines, N-(α -acyloxy)alkyl-N-alkylnitrosamines, and 3,3-dimethyl-1-phenyltriazene. The organ specificity of certain carcinogenic chemicals can be determined by the half-lives of their ultimate carcinogens, which may act to prevent their distribution in the body by covalent reactions in the organs (cells) in which they are generated. In human liver, large interindividual differences in the activity of carcinogen-activating enzymes were noted. Aryl hydrocarbon-hydroxylase (AHH) activity and microsome-mediated mutagenicity were measured using the hepatocarcinogens N-nitrosomorpholine, N-nitroso-N'-methylpiperazine, and vinyl chloride as substrates. When AHH activity in liver specimens from human subjects was plotted against the respective microsome-mediated mutagenicity for *Salmonella typhimurium*, a positive correlation was obtained for the rate of oxidative benzo(a)pyrene metabolism and mutagenicity in the presence of all three substrates. Thus, differences in tissue-specific activation processes of chemical carcinogens appear to be contributing factors in the production of tumors only in certain organs and may also condition the carcinogenic response in different individuals when they are exposed to the same level of environmental carcinogens. (34 refs)

79-6166 Mutagenic Activation of 2-Acetylaminofluorene by Guinea-Pig Liver Homogenates: Essential Involvement of Cytochrome P-450 Mixed-Function Oxidases. (Eng) Takeishi, K. (Dept. Immunology, Virology, Saitama Cancer Center Res. Inst., Ina-machi, Saitama 362, Japan); Okuno-Kaneda, S.; Seno, T. *Mutat Res* 62(3): 425-437; 1979.

2-Acetylaminofluorene (AAF) was highly mutagenic to *Salmonella typhimurium* strain TA98 when activated by a liver post-mitochondrial supernatant fraction (S9 fraction) from guinea-pigs in spite of the resistance of this species to AAF carcinogenesis and the low capacity of guinea-pig liver for N-hydroxylation of AAF. The mutagenicity was comparable to or higher than that resulting from activation by mouse- or rat-liver S9 fraction and was not enhanced by treatment with cytochrome P-450 inducers (a combination of phenobarbital and 5,6-benzoflavone). In an attempt to understand this unexpected result, the possible role of a

cytochrome P-450 mixed-function oxidase system in the mutagenic activation of AAF by guinea-pig liver (similar to the enzymatic activation occurring in mouse liver) was investigated. The mutagenic activation was completely dependent on the addition of a co-factor, NADPH, to the mutation assay system; completely suppressed by antiserum against NADPH-cytochrome c reductase; and sensitive to a cytochrome P-450 inhibitor, 7,8-benzoflavone. These results indicate that the cytochrome P-450 enzyme system is essentially involved even in the mutagenic activation of AAF by guinea-pig-liver S9 fraction, and the mechanism of action responsible for the observed high mutagenic potential of AAF is discussed based on both these and other data. (39 refs)

- 79-6167 In Vitro Metabolism and Activation of Carcinogenic Aromatic Amines by Subcellular Fractions of Human Liver. (Eng) Dybing, E. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); von Bahr, C.; Aune, T.; Glaumann, H.; Levitt, D. S.; Thorgeirsson, S. S. *Cancer Res* 39(10): 4206-4211; 1979.

The in vitro metabolism and metabolic activation of 2-acetylaminofluorene (AAF), 2-aminofluorene (AF), and 2,4-diaminoanisole (DAA) to mutagenic (for *Salmonella typhimurium* strain TA98) and covalently protein-bound intermediates by subcellular fractions from seven normal human livers were studied. AAF was extensively metabolized by all microsomal samples. 7-hydroxy-2-acetylaminofluorene was the major hydroxylated metabolite, but N-hydroxy-2-acetylaminofluorene (N-hydroxy-AAF) was also formed to a substantial degree, ranging from 4% to 10% of the total metabolites in the seven samples. Electrophoresis of the microsomal fractions revealed several polypeptides with mol wt of 40,000-60,000. Two polypeptides with mol wt of approx 54,000 and 55,000, respectively, corresponded to those seen in rat liver microsomes following pretreatment with 3-methylcholanthrene. The in vitro mutagenicity of AAF in the individual samples corresponded with those of AF and DAA, as did the degree of AAF N-hydroxylation. N-hydroxy-AAF was converted to mutagen(s) by both human liver microsomal and cytosol fractions, presumably via deacetylation. A poor association between the extent of covalent binding of AAF to liver microsomal proteins and the degree of mutagenicity in the *Salmonella* system was observed among the samples, possibly indicating that the reactive metabolite(s) arylating the protein differs from that causing the frame-shift mutation in the bacteria. The results indicate that there are qualitative similarities between the subcellular fractions from human liver and those from rat, mouse, and rhesus monkey. (35 refs)

- 79-6168 Quantitative and Qualitative Aspects of the Binding of N-hydroxy-2-Acetylaminofluorene to Hepatic Chromatin Fractions. (Eng) Schwartz, E. L. (Dept. Pharmacology, Michigan State Univ., East Lansing, MI 48824); Goodman, J. I. *Chem Biol Interact* 26(3): 287-303; 1979.

The binding of N-hydroxy-2-acetylaminofluorene (AAF: 0.03% of the diet or injected ip) to hepatic chromatin fractions of male Sprague-Dawley rats was studied. After a single injection (0.4 μ mol/100 g body wt), AAF was found covalently bound to chromatin RNA, protein, and DNA, the amount of carcinogen bound to RNA being 5-fold greater than that bound to DNA and 10-fold greater than that bound to protein. Loss of carcinogen from RNA was rapid, whereas persistent binding to DNA equal to 15% of the initial values was observed. A glycerol gradient

chromatin fractionation procedure and a selective $MgCl_2$ chromatin precipitation procedure were used to identify DNA-bound carcinogen. Three chromatin fractions were described: template expressed euchromatin, repressed heterochromatin, and highly condensed pelleted heterochromatin. With both fractionation procedures, the initial (2 hr) binding of carcinogen was greatest on the euchromatin DNA. Loss of carcinogen was significantly faster from the euchromatin than from the other fractions. By 10 days after a single injection, the largest amount of bound fluorene residues were located on the pelleted heterochromatin DNA, <5% of the initial values being associated with the other fractions. When AAF was incorporated in the diet, loss from the pelleted heterochromatin DNA was enhanced, and loss from the euchromatin DNA was reduced. Thin-layer chromatography confirmed the covalent nature of the carcinogen modification of DNA and demonstrated two separate carcinogen-purine base adducts: N-(guanine-8-yl)-N-aminofluorene and 3-(guanine-N²-yl)-N-acetylaminofluorene. The proportion of the latter adduct was $23 \pm 1.2\%$ greater on the pelleted heterochromatin DNA than on the other two chromatin fractions ($p < 0.05$). (53 refs)

- 79-6169 Mutagenic Effect of a Chemical on Bacterial Strain of *Salmonella typhimurium* (Ames Test): Method and Results for Several Known Carcinogens. (Fre) Hesbert, A. (Institut National de Recherche et de Securite, avenue de Bourgogne, B.P. no. 27, 54500 Vandoeuvre-les-Nancy, France); Cavelier, C.; Bottin, M. C.; Lemonnier, M. *Arch Mal Prof* 40(3/4): 437-457; 1979.

The mutagenicity of known chemical carcinogens was tested using the *Salmonella typhimurium* strains TA 98, TA 100, TA 1538, TA 1535, TA 1537, and TA 1530, with and without metabolic activation by rat hepatic microsomal fraction. Ames test results were considered positive if the number of revertants per dish exceeded double the number of spontaneous revertants. All substances tested (2-aminofluorene, 2-acetylaminofluorene, 9-aminoacridine, 1-aminoanthracene, 2-aminoanthracene, dibenzo(a,i)pyrene, benzo(a)pyrene, 3-methylcholanthrene, chrysene, 7,12-dimethylbenz(a)anthracene, 4-nitroquinoline-1-oxide, N-methyl-N'-nitro-N-nitrosoguanidine, methylmethane sulfonate, sodium azide, aflatoxin B1, and vinyl chloride) were found to be mutagenic, both with and without metabolic activation. (14 refs)

- 79-6170 Pretreatment with Acetylaminofluorene Enhances the Repair of O⁶-Methylguanine in DNA. (Eng) Buckley, J. D. (Paterson Lab., Christie Hosp., Manchester, England); O'Connor, P. J.; Craig, A. W. *Nature* 281(5730): 403-404; 1979.

Possible interrelationships of two hepatocarcinogens were investigated, at the level of DNA repair. Male Wistar rats (7-8 wk old) were fed a standard diet containing 0.06% 2-acetylaminofluorene (AAF) for 3 wk followed by 1 wk on a normal diet. After three such feeding cycles, the rats received one dose of dimethylnitrosamine (DMN: 1.0, 5.5 or 9.0 mg/kg, ip). The rats were killed at various times over a 48-hr period, liver DNA was isolated, and the amounts of O⁶-methylguanine and 7-methylguanine were determined. Measurement of exhaled radiolabeled CO₂ indicated that the rate of metabolism of [¹⁴C-methyl]-labeled DMN was similar in control and AAF-pretreated rats. At 5 hr, the level of 7-methylguanine was similar in liver DNA from control and AAF-pretreated rats, and the amount

formed was linearly related to dose. The amounts of O⁶-methylguanine were also dose-related but were significantly lower for the AAF-pretreated rats. O⁶-Methylguanine repair was enhanced at each dose level; at 9 mg/kg, this enhancement occurred to such an extent that there was no detectable inhibition of the repair process. The repair of O⁶-methylguanine was relatively more active at lower doses of DMN in the control and AAF-pretreated rats. The enhanced repair seen in the AAF-pretreated rats might be due to the induction of a general repair mechanism or may be explained by the activation of a more specific repair system due to the formation of small amounts of an AAF-adduct at the O⁶-position of guanine in DNA. (19 refs)

- 79-6171 Histochemical Studies on Peroxisomes of Mouse Liver During N,N'-2,7-Fluorenylenebisacetamide Carcinogenesis. (Eng) Gotoh, M. (Dept. Pathology, Cancer Res. Inst., Sapporo Medical Coll., Sapporo 060, Japan); Furukawa, K.; Mochizuki, Y.; Tsukada, H. *Tumor Res (Sapporo)* 13: 20-29; 1978.

The histogenesis of hepatic tumors in male ICR/JCL mice fed N,N'-2,7-fluorenylenebisacetamide was examined, and the findings were correlated with changes in peroxisome levels, as demonstrated by 3,3'-diaminobenzidine histochemistry. Hyperplastic areas appeared in periportal regions of the liver lobules containing hypertrophic hepatocytes. Small basophilic and large eosinophilic cells were found in these areas. Histologic and histochemical observations suggest that the latter cells are derived from the former through maturation. Small tumors (<2 mm in diameter) also consisted of both types of cells, and they lacked histologic evidence of malignancy. With ethyl- α -p-chlorophenoxyisobutyrate administration, peroxisomal proliferation was induced in these cells, especially in the larger cells. Tumors >2 mm in diameter showed a more complex histologic pattern. Some tumors resembled Walker's type A tumor, and others showed either a mixture of type A areas and areas of small hyperbasophilic cells or a mixture of basophilic and eosinophilic cells with considerable cell atypia and mitotic figures. Histologically, these tumors are considered malignant, except for the type A-like tumors. The number of peroxisomes varied depending on whether basophilic or eosinophilic cells were present, which suggests that peroxisome level is correlated with the degree of cell differentiation. However, the induction of peroxisomal proliferation was almost lost in these tumor cells. (24 refs)

- 79-6172 α -Fetoprotein Levels and Hepatic Alterations During Chemical Carcinogenesis in C57BL/6N Mice. (Eng) Becker, F. F. (Dept. Pathology, Univ. Texas System Cancer Center, Houston, TX 77030); Sell, S. *Cancer Res* 39(9): 3491-3494; 1979.

The hepatic alterations and α -fetoprotein (AFP) levels induced by the insecticide chlordane (CRD, 25 or 50 ppm in the feed) and the chemical hepatocarcinogen acetylaminofluorene (AAF, 0.045% or 0.03% of the diet) were compared using male C57BL/6N mice. Mortality was generally higher among mice given the higher dose of each drug; death was frequently related to pneumonia. Benign proliferative lesions (BPL) were observed in 7% of the mice given 50 ppm CRD, 2% of those given 25 ppm CRD, 4% of those given 0.045% AAF, and 2% of those given 0.03% AAF. Significant elevations in serum AFP were observed in 8% of AAF-treated mice, usually after 52 wk of treatment, and in 15% of CRD-treated mice, usually after 38 wk of treatment. Every mouse with a

malignant lesion had elevated AFP levels, and every mouse with elevated AFP levels demonstrated a malignant lesion. However, none of the mice with BPL alone and none of those receiving transplanted primary hepatocellular carcinomas (PHC) had elevated AFP levels. PHC were detected in 18% of AAF-treated mice, usually after 61 wk of treatment, and in 27% of CRD-treated mice, usually after 48 wk of treatment. The PHC were generally well differentiated with trabeculae. Three of six AAF-induced PHC and 5/12 CRD-induced PHC demonstrated growth after transplantation into new hosts. (22 refs)

- 79-6173 Metabolic Activation of Arylhydroxamic Acids by N-O-Acyltransferase of Rat Mammary Gland. (Eng) King, C. M. (Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI 48201); Traub, N. R.; Lortz, Z. M.; Thissen, M. R. *Cancer Res* 39(9): 3369-3372; 1979.

The lactating mammary glands of rats contain an arylhydroxamic acid N-O-acyltransferase that catalyzes the formation of arylamine-substituted nucleic acid on incubation with N-hydroxy-N-2-acetylaminofluorene or N-hydroxy-N-4-acetylaminobiphenyl and transfer RNA. The acyltransferase activity migrates as a single component with a mol wt of 28,000 on gel filtration on Sephadex G-100. Acyltransferase activities of the lactating mammary glands of Sprague-Dawley rats were approx twice those of the less susceptible Fischer strain, as determined by assay with either hydroxamic acid. The fluorene substrate was 15 times as efficient as the biphenyl compound in promoting adduct formation. Ribosomal RNA adducts formed in vivo after administration of N-hydroxy-N-2-acetylaminofluorene were consistent with an acyltransferase mechanism of activation, in that the adducts did not retain the acetyl group. (20 refs)

- 79-6174 DNA-Damaging and Mutagenic Effect of 1,2-Dimethylhydrazine on *Bacillus subtilis* Repair-deficient Mutants. (Eng) Felkner, I. C. (Dept. Biological Sciences, Texas Tech Univ., Lubbock, TX 79409); Hoffman, K. M.; Wells, B. C. *Mutat Res* 68(1): 31-40; 1979.

1,2-Dimethylhydrazine (DMH) was assayed for mutagenicity and DNA-damaging effects in several *Bacillus subtilis* repair-deficient mutants. The in vivo DNA-repair assay demonstrated that the *B. subtilis* *recA8* and *MC-1* strains were killed at a frequency over 300-fold that of the wild-type parent. Since these *Rec⁻* strains are isogenic with the wild-type strain, except for the reduced ability to repair DNA damage, it is inferred that the increased killing was due to a DNA-damaging effect. DMH was mutagenic to *B. subtilis* strain TKJ6321 at several concentrations with and without metabolic activation. Metabolic activation reduced the mutagenicity significantly. The DNA isolated from a DMH-treated *Rec⁻* strain had altered spectroscopic characteristics and gave a greatly reduced transformation efficiency. Treatment of a wild-type strain with DMH did not alter the spectroscopic properties and had little effect on transformation. These studies show that DMH can alter DNA in vivo, exert DNA-damaging activity, and cause a mutagenic response in repair-deficient strains of *B. subtilis*. These activities are pH-dependent, pH 6.5 giving an optimum response. It seems likely, therefore, that pH is an extremely important determinant in colon tumor initiation by DMH. (29 refs)

- 79-6175 The Oncological Characteristics of Colonic Polyps in Humans in View of Morphogenesis of Experimental

Intestinal Tumors. (Eng) Pozharisski, K. M. (Lab. Experimental Tumors, Petrov Res. Inst. Oncology, USSR Ministry Public Health, Leningrad 188646, USSR); Chepick, O. F. *Tumor Res (Sapporo)* 13: 40-56; 1978.

The morphology and morphogenesis of intestinal epithelial tumors induced by 1,2-dimethylhydrazine in >2,000 rats and of 1,415 polypoid lesions in the human colon and rectum were compared. The development of experimental cancer starts with expansion of the proliferative zone in the intestinal crypts. The first lesion to occur is carcinoma in situ (CIS), which develops in the superficial layers of the flat mucosa. Further evolution of CIS with invasion of the lamina propria leads to superficial cancer development. Invasive cancer develops when neoplastic structures extend into the submucosa. Therefore, experimental intestinal adenocarcinoma appears de novo. Morphogenetic studies showed that the preinvasive stage may persist for a long time. In such cases, structural and cytological signs of epithelial atypism and pleomorphism may be of vital importance for the detection of malignancy. With noninvasive polypoid lesions in humans, emphasis should be placed on detection of the following morphologic manifestations of atypia: a considerable decrease or absence of goblet cells, epithelial pseudostratification or even a multilayered structure, mitoses in the superficial areas of tumors and an increasing proportion of abnormal mitoses, appearance of papillary and villous structures and changes in their configuration, bizarre outlines of tumor glandules, cellular and nuclear polymorphism, and the appearance of cribriform structures, numerous plasma cells, and karyorrhexis-affected lymphocytes in the tumor stroma. Invasion was detected in 70% of the dissected intestinal segments in which these changes were observed upon biopsy. No morphologic signs of malignancy were detected in adenomatous polyps. However, CIS and superficial cancer in a background of intact flat mucosa were quite frequent. Sometimes even very small (2-3 mm in diameter) exophytic neoplasms showed morphologic signs of malignancy, including invasion. These findings suggest that polypoid cancers and glandular villous tumors are malignant from the beginning. In the absence of invasion, they may be identified as CIS or superficial cancer. (91 refs)

79-6176 Effect of Dietary Fiber on the Induction of Colorectal Tumors and Fecal β -Glucuronidase Activity in the Rat. (Eng) Bauer, H. G. (Dept. Surgery, Univ. Hosp. Lund, S-221 85 Lund, Sweden); Asp, N. G.; Oste, R.; Dahlqvist, A.; Fredlund, P. E. *Cancer Res* 39(9): 3752-3756; 1979.

The effects of three types of dietary fiber -- wheat bran (WB, 20% of the basic diet), carrot fiber (CF, 20% of the basic diet), and citrus pectin (CP, 6.5% of the basic diet) -- on the induction of colorectal tumors in male Sprague-Dawley rats by 1,2-dimethylhydrazine (DMH, 15 mg/kg/wk for 12 wk, sc) were studied. The dry fecal weights of the rats fed CF and CP were slightly higher than those fed control diets, and those of rats fed WB were two-fold greater. Tumors were detected in 87%-97% of all rats, the frequency of tumors being significantly higher in the group given CP. In about 25%-30% of the cases, the tumors were located in the proximal colon. They were primarily infiltrating adenocarcinomas of two types, endophytic and exophytic. There were few metastases. Adenocarcinomas in situ were also observed, as were adenomas. In each group of rats, approx 20 infiltrating adenocarcinomas of the small intestine were observed, and tumors in front of the outer orifice of the ear duct were seen in about 15-20 rats in each group. The frequency of ear duct tumors was higher in the CP group. Weight gain and food consumption were the same in all groups, and there were no differences in the β -glucuronidase

(BGC) activities of the ileum or colon between groups. However, feces from the rats fed CP had significantly higher BGC activities than did the feces from other groups. Fecal BGC activity might be one factor of importance in the activation of DMH. (18 refs)

79-6177 A DNA-binding Protein Class Appearing in DMH-induced Carcinogenesis. (Eng) Allfrey, V. G. (Rockefeller Univ., New York, NY 10021); Boffa, L. C.; Vidali, G. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, R. W., ed. (New York; Elsevier): 590 pp.; 351-367; 1978.

Changes in the composition and rates of synthesis of nuclear proteins in the crypt epithelial cells during 1,2-dimethylhydrazine (DMH)-induced colonic carcinogenesis in the rodent were studied. Two protein classes of mol wt 44,000 (TNP1) and 62,000 (TNP2) were selectively synthesized at accelerated rates early in carcinogenesis. TNP1 was found in the dividing tumor cell population, whereas TNP2 was enriched in the nondividing cell population. TNP1 showed a high affinity for DNA and was partially purified by DNA-affinity chromatography. Limited digestions of adenocarcinoma nuclei with DNase I led to a preferential release of TNP1 proteins without a corresponding release of the TNP2 cells. Thus, the TNP1 proteins appear to be associated with the transcribing regions of the genome in the tumor cell nuclei. Levels of histone acetylation were altered in vivo by exposing cultured tumor cells to sodium butyrate, an inhibitor of histone deacetylase activity. DNA in acetylated chromatin was much more susceptible to DNase I attack, and the multi-acetylated forms of the key nucleosomal histones H3 and H4 were preferentially released at early times. Specific sets of nonhistone nuclear proteins, including TNP1 and members of the high-mobility group, were released at the same time. (52 refs)

79-6178 The Demonstration of a Cooperative Action of Bacterial and Intestinal Mucosal Enzymes in the Activation of Mutagens. (Eng) Mc Coy, E. C. (Dept. Microbiology, New York Medical Coll., Valhalla, NY 10595); Petrullo, L. A.; Rosenkranz, H. S. *Biochem Biophys Res Commun* 89(3): 859-862; 1979.

The possibility of a cooperative action of bacterial and intestinal mucosal enzymes in the conversion of 2-aminofluorene and 2-aminoanthracene to mutagens was investigated. Mutagenic activity for *Salmonella typhimurium* TA1538 was determined by the Ames procedure using the usual rat liver microsome preparation, microsomes from rat intestinal mucosa (IM), a cell-free extract derived from a human strain of *Bacteroides fragilis* (Bf), or a combination of Im and Bf. Both test chemicals were readily converted to mutagens by the liver microsomes, but the microsomes prepared from the intestinal mucosa had little or no such activity. The cell-free bacterial extracts exhibited various levels of activity. However, mixtures of the intestinal and bacterial enzyme preparations consistently showed activities that were not only significantly higher than the activity of either preparation alone but also were more than additive, presumably demonstrating a synergistic action. It is suggested that anaerobic bacteria in the colon may convert a colon-specific carcinogen to a penultimate metabolite that could then be transformed to the ultimate form by intestinal enzymes. - 79-6179 Nitrite-Lipid Reaction in Aqueous System: Inhibitory Effects on N-Nitrosamine Formation. (Eng) Kurechi, T. (Tokyo Coll. Pharmacy, 1432-1 Horinouchi, Hachioji, Tokyo 192-30, Japan); Kikugawa, K. *J Food Sci* 44(5): 1263-1266, 1271; 1979.

The chemical interaction of lipids and lipid-containing foods with nitrite in a mild acidic aqueous system was investigated. Methyl linoleate-coated silica gel, Intralipid, cow's milk, mayonnaise, yolk, and miso reduced a considerable amount of nitrite. Methyl linoleate-coated silica gel and cow's milk extensively prevented the formation of carcinogenic N-nitrosamines. The unsaturated fatty acid residues seemed to be responsible for the interaction of lipids with nitrite. Methyl linoleate was changed into two or more unidentified products; neither was the hydroperoxide of the ester. (25 refs)

- 79-6180 Transplacental Mutagenesis of Products Formed in the Stomach of Golden Hamsters Given Sodium Nitrite and Morpholine. (Eng) Inui, N. (Biological Res. Center, 23, Nakogi, Hatano, Kanagawa 257, Japan); Nishi, Y.; Taketomi, M.; Mori, M.; Yamamoto, M.; Yamada, T.; Tanimura, A. *Int J Cancer* 24(3): 365-372; 1979.

Hamster embryos were exposed in utero to the action of sodium nitrite (NaNO_2) and morpholine (Mo) administered simultaneously by stomach tube (500 mg/kg) to the mothers on the 11th or 12th day of pregnancy. Embryo cells were examined for chromosomal aberrations, micronuclear formation, morphological or malignant transformation, and drug resistance mutations. For detection of induced mutations, the embryo cells were cultured in normal medium for 72 hr and then transferred to medium containing 10 or 20 $\mu\text{g}/\text{ml}$ of 8-azaguanine (8AG) or 1 millimolar ouabain (Oua). The number of 8AG-, Oua-resistant colonies was markedly increased after administration of NaNO_2 and Mo. The embryonic fibroblasts also showed a markedly increased frequency of micronucleation and a slight increase in chromosome aberrations. This treatment also caused morphological or malignant transformation of fetal cells. After cultivation in vitro, cells from some transformed colonies produced tumors when inoculated into the cheek pouch of young golden hamsters. N-nitroso-morpholine (N-Mo; 100 or 200 mg/kg, po), used as a positive control, had the same transplacental biological actions on embryonic fibroblasts. However, transplacental administration of Mo alone was ineffective, and the single administration of NaNO_2 had only slight biological effects. N-Mo was produced in the stomachs of animals treated simultaneously with NaNO_2 and Mo. A small amount of the nitrosamine N-nitrosodimethylamine (DMN) was detected in the stomach after a single dose of NaNO_2 . (23 refs)

- 79-6181 Is Acrylonitrile Carcinogenic? (Dut) Aldershoff, W. G. (Volksgezondheid, Hoofdinsektie, Netherlands). *Chem Weekbl* 75(32): 2; 1979.

Acrylonitrile, administered in high doses, was found to be carcinogenic in rats; it induced mainly brain tumors. However, a survey of 700 occupationally exposed workers showed no increase in the cancer risk. According to strict calculations, the annual tumor risk for humans taking doses of up to 0.1 μg acrylonitrile/day lifelong is 1/200,000,000. (no refs)

- 79-6182 N-Nitrosamines in the Rubber and Tire Industry. (Eng) Fajen, J. M. (Div. Surveillance, Hazard Evalua-

tion and Field Studies, Natl. Inst. Occupational Safety and Health, Cincinnati, OH 45226); Carson, G. A.; Rounbehler, D. P.; Fan, T. Y.; Vita, R.; Goff, U. E.; Wolf, M. H.; Edwards, G. S.; Fine, D. H.; Reinhold, V.; Biemann, K. *Science* 205(4412): 1262-1264; 1979.

Four rubber industry factories (tire chemical, industrial rubber products, aircraft tile, and synthetic rubber and latex) were surveyed for the presence of N-nitrosamines. N-Nitrosodimethylamine (NDMA) was found as an air pollutant at both the chemical factory (0.05-0.5 $\mu\text{g}/\text{m}^3$) and the industrial rubber products factory (0.07-0.14 $\mu\text{g}/\text{m}^3$). N-nitrosomorpholine (NMOR) was found as an air pollutant inside both the chemical factory and the aircraft tire factory at 0-27 $\mu\text{g}/\text{m}^3$. A man doing moderately heavy work near the contaminated area in the tire chemical plant would be exposed to NMOR at 44 $\mu\text{g}/\text{day}$ and to NDMA at 4.8 $\mu\text{g}/\text{day}$. In the most highly contaminated areas of the aircraft tire factory, a similar worker would breathe 260 μg NMOR daily. A typical worker is probably exposed to one-half to one-fifth these levels. Several recent studies have shown increased rates of lung and gastrointestinal (including colorectal) cancers among workers in several work areas where this survey detected the highest amounts of N-nitrosamine contamination. More extensive workplace monitoring must be carried out before one can speculate on the possible involvement of N-nitroso compounds in the etiology of cancer in rubber workers. (17 refs)

- 79-6183 Studies on the Distribution and Metabolism of ^{14}C -Dimethylnitrosamine in Foetal and Young Mice. (Eng) Johansson-Brittebo, E. (Dept. Toxicology, Univ. Uppsala, Uppsala, Sweden); Tjalve, H. *Acta Pharmacol Toxicol (Copenh)* 45(1): 73-80; 1979.

The metabolism of ^{14}C -dimethylnitrosamine (DMN) by the liver of fetal and young C57BL mice was studied in vitro, using $^{14}\text{CO}_2$ production and incorporation of radioactivity into acid-insoluble macromolecules as indices of decomposition. In pregnant mice inoculated with ^{14}C -DMN (2.5 μCi ; 35 μg) whole-body autoradiography was performed with hemisections at -80 C (to prevent evaporation of the volatile DMN) and with dry tape sections (to localize the nonvolatile metabolites). The results indicated that the nonmetabolized substance was transported to the fetal tissues with a uniform distribution and without the formation or accumulation of nonvolatile metabolites. Autoradiography in young (1-10 days old) and adult mice showed a high level of metabolites in the liver 5 min after the administration of ^{14}C -DMN (0.25 $\mu\text{Ci}/\text{g}$; 3.5 mg/kg). No DMN metabolism could be detected in in vitro incubations of liver tissue obtained from fetuses on the last day of gestation. However, in vitro experiments with livers of 1- to 5-day-old mice indicated that there was a rapid increase in enzyme activity after birth. In in vivo studies, there was an increased incorporation of radioactivity in the acid-insoluble macromolecules of the liver and a decreased exhalation of $^{14}\text{CO}_2$ in 10- and 14-day-old mice compared with 21- and 60-day-old mice. Thus, the in vivo metabolism of DMN differs between young and older mice. (19 refs)

- 79-6184 Persistence and Accumulation of (Potential) Single Strand Breaks in Liver DNA of Rats Treated with Diethylnitrosamine or Dimethylnitrosamine: Correlation with Hepatocarcinogenicity. (Eng) Floot, B. G. (Chemical Carcinogenesis Div., Div. Clinical Oncology, Antoni van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam,

CHEMICAL CARCINOGENESIS

Netherlands); Philippus, E. J.; Hart, A. A.; Den Engelse, L. *Chem Biol Interact* 25(2/3): 229-242; 1979.

The effects of diethylnitrosamine (DEN) and dimethylnitrosamine (DMN) on the sedimentation pattern of [³H]thymidine-labeled Sprague-Dawley female rat liver DNA in alkaline sucrose gradients were studied with regard to time and dose dependency. In experiments at 1-56 days after a single ip injection, it was observed that potential single strand breaks induced by DEN were repaired at a low rate. At 56 days the sedimentation pattern was still grossly abnormal. Half-life values of 27 and 46 days were observed after 134 mg/kg DEN (approx 45% of the LD₅₀) and 13.4 mg/kg DEN, respectively. Identical experiments after DMN (10 mg/kg, corresponding to about 35% of the LD₅₀) showed almost complete return to control sedimentation patterns within 56 days after injection. Experiments at 6 or 56 days after the last of a series of 5 or 10 weekly injections of DEN (13.4 mg/kg) showed that a major part of DEN-induced damage (measured as single strand breaks) is of a persistent and accumulating character. No accumulation of DMN-induced rat liver lesions was observed. It is concluded that DNA fragmentation and lack of DNA repair is not a consequence of hepatotoxicity. Since at equimolar doses DEN gives appreciably less DNA alkylation (including O⁶-alkylguanine) but is much more effective both as an inducer of preneoplastic liver lesions and as a hepatocarcinogen when compared with DMN, the formation of persistent (and accumulating) DNA damage after DEN administration might be related to the process of liver tumor formation. (15 refs)

- 79-6185 Early Effects of Dimethylnitrosamine on Protein Chain Initiation and Postmicrosomal Polyadenylic Acid-containing RNA Content in Mouse Liver. (Eng) Nygard, O. (Dept. Cell Physiology, Wenner-Gren Inst., Univ. Stockholm, S-113 45 Stockholm, Sweden); Hultin, T. *Cancer Res* 39(9): 3349-3352; 1979.

The early effects of dimethylnitrosamine (DMNA: 17.5, 37.5, and 75 mg/kg) on polypeptide chain initiation and messenger RNA (mRNA) levels in mouse liver were studied in a mouse liver S-30 system. The inhibition of protein synthesis after DMNA administration was associated with a reduced capacity of the S-30 system to form 80S ribosomal initiation complexes. The binding of formylatable methionyl transfer RNA to polysomes was also depressed. In the assay system, the initiation defect was detectable slightly later than the decrease in protein synthesis. Addition of mRNA stimulated both translation and 80S initiation complex formation, but it could not fully restore the activity of the S-30 system from DMNA-treated mice. A loss of polyadenylic acid-containing RNA from the postmicrosomal subfraction of the S-30 fraction was observed as early as 15 min after DMNA administration. Later, polyriboadenylic acid also decreased in the microsomal fraction. Monosomes accumulating in response to DMNA treatment were deficient in mRNA, as determined by polyriboadenylic acid analysis. Conversely, the proportion of polyriboadenylic acid in the remaining polysomes increased, indicating that the mRNA had become less densely occupied with ribosomes. (20 refs)

- 79-6186 Alkylation of DNA and RNA by [¹⁴C]Dimethylnitrosamine in Hydroxyurea-synchronized Regenerating Rat Liver. (Eng) Rabes, H. M. (Inst. Pathology, Univ. Munich, Thalkirchner Strasse 36, 8000 Munich 2, W. Germany); Kerler, R.; Wilhelm, R.; Rode, G.; Riess, H. *Cancer Res* 39(10): 4228-4236; 1979.

Cell cycle-dependent DNA base alkylation and carcinogenic effects in the regenerating male Wistar AF/Hann rat liver were studied following a single ip injection of [¹⁴C]dimethylnitrosamine (DMN, 1.43 mg/kg). Overlapping of cell cycle compartments after partial hepatectomy was prevented by continuous infusion of hydroxyurea (HU), beginning 14 hr after surgery and continuing for up to 25 hr. Metabolic incorporation from DMN via 1-carbon pool differed at various phases in the cell cycle due to changes in DMN metabolism and DNA- and RNA-synthetic activity. A high extent of metabolic incorporation into the adenine and, to a greater extent, guanine of DNA was limited to the period of synchronized DNA synthesis with a rapid decrease in G₂-M. Labeling of purine bases of RNA was maximal during G₁ and G₂-M. The preferential site of alkylation of DNA purine bases was the N-7 of guanine. The molar fraction of 7-methylguanine 2 hr after DMN injection was max in G₁, decreased during S and G₂-M, and was lowest during HU infusion. The molar fraction of O⁶-methylguanine increased during G₁ and showed a rapid decline during S and G₂-M. During DNA synthesis, the ratio of O⁶-methylguanine to 7-methylguanine was significantly lower than during G₀ and G₁, whereas the molar fractions of 7-methylguanine were of the same order of magnitude during G₁, S, and G₂-M. The data suggest that the extent and site of alkylation and also the specific position of a cell in the cell cycle determine the probability of malignant transformation by DMN. Base mispairing as well as an error-prone repair during DNA synthesis could be the mechanism responsible for this process. (66 refs)

- 79-6187 Effect of Urethan, Dimethylnitrosamine, Paraquat, and Butylated Hydroxytoluene on the Aerobic Lactic Acid Production of Mouse Lung and on the Activity of Key Glycolysis Enzymes. (Hun) Arany, I. (Kozegeszsegtani es Jaryanytani Intezet, Debreceni Orvostudományi Egyetem, Debrecen, Hungary); Rady, P.; Bojan, F.; Kertai, P. *Egeszsegtudomány* 23(2): 142-146; 1979.

Urethan and dimethylnitrosamine, which cause lung tumors in CFLP mice, permanently increased aerobic lactic acid production and the activity of key glycolysis enzymes in the mouse lung during the period preceding tumor development. The effect of Paraquat and butylated hydroxytoluene, which do not cause lung tumors, was transitory. Determination of these two parameters appears to be suitable for the rapid in vivo testing of carcinogens. (20 refs)

- 79-6188 Long-Term Experiment of Maximal Non-carcinogenic Dose of Dimethylnitrosamine in Rats. (Eng) Arai, M. (Dept. Pathology, Fujita-Gakuen Univ., Sch. Health Science, Dengakugakubo, Kutsukake-cho, Toyoake, Aichi-ken 470-11, Japan); Aoki, Y.; Nakanishi, K.; Miyata, Y.; Mori, T.; Ito, N. *Gann* 70(4): 549-558; 1979.

The incidence of neoplasms in male and female Wistar rats fed dimethylnitrosamine (DMN, 0.1, 1.0, or 10 ppm in the diet for 96 wk) was studied. The DMN-treated groups did not differ significantly from controls or each other in body wt, food or water consumption, or general condition. The WBC count was increased and the RBC count decreased in rats given 10 ppm DMN, but there were no differences between groups in the results of liver function tests (SGOT, SGPT, alkaline phosphatase, cholinesterase). In rats given >1.0 ppm DMN, nodular hyperplasias of the liver, hepatocellular carcinomas, and hemangioendotheliomas were observed. Pyelonephritis was found in all groups but was most frequent (80%) and severe in males given 10 ppm DMN. The data

suggest that the minimum carcinogenic dose of DMN for the rat is 1.0 ppm in the diet and that the noneffective level is approx 0.1 ppm. (26 refs)

- 79-6189 Systemic Promoting Action and Leukemogenesis in SWR Mice by Phorbol and Structurally Related Polyfunctional Diterpenes. (Eng) Armuth, V. (Experimental Biology Unit, Weizmann Inst. Science, Rehovot, Israel); Berenblum, I.; Adolf, W.; Opferkuch, H. J.; Schmidt, R.; Sorg, B.; Hecker, E. *J Cancer Res Clin Oncol* 95(1): 19-28; 1979.

Six structurally related compounds representing the polyfunctional diterpenes of the tiglane, ingenane, and lathyrane types (phorbol, 4-O-methylphorbol, 12-deoxyphorbol, and 4 α -phorbol; ingenol; and lathyrol and 6,17-epoxylathyrol, respectively) were tested for systemic promoting and leukemogenic activity in SWR mice. For systemic initiation soon after birth, dimethylnitrosamine (DMN, 15 μ g) was injected sc. The diterpenes were administered ip (0.5 μ mole per injection) either with or without prior systemic initiation with DMN. Systemic promotion was expressed for liver by induction of adenomas with all the diterpenes tested, some of which were more potent than phorbol. The relatively high dose of DMN used as initiator prevented an evaluation of promoting action in relation to lung carcinogenesis. The leukemogenic effect of phorbol in SWR mice was confirmed at three different dose levels (0.25, 0.5, and 1.0 μ mole). The other diterpenes tested had no significant leukemogenic activity. The leukemogenic action of phorbol was totally inhibited by prior DMN injection. The lack of correlation between promoting action in skin, systemic promoting action in liver, and leukemogenic action of the diterpenes tested is discussed. (18 refs)

- 79-6190 Sequential Changes in DNA Polymerases α and β During Diethylnitrosamine-induced Carcinogenesis. (Eng) Craddock, V. M. (MRC Toxicology Unit, Woodmansterne Road, Carshalton, Surrey, England); Ansley, C. M. *Biochim Biophys Acta* 564(1): 15-22; 1979.

Sequential changes in DNA polymerases α and β during carcinogenesis induced by diethylnitrosamine (DEN: 90 ppm in the diet for 15 wk) in female Wistar rats were studied. When animals were fed DEN, the "bound" enzymes in the liver fractionated on sucrose gradients in a manner similar to the polymerases isolated from normal liver. Polymerase α activity increased to a maximum 6-9 wk after DEN feeding and then decreased, whereas polymerase β increased throughout the 15 wk of DEN feeding. Within 3 wk after termination of DEN feeding, polymerase β activity had fallen to within the normal range. In rats given DEN, there was an increase in the activity of "soluble" high mol wt polymerase α , the maximum increase at 6-9 wk correlating with the increase in polymerase α in the bound fraction. There was no consistent change in the activity of polymerase β . The results support the views that polymerase α is involved in DNA replication, that the polymerase β functions in repair replication, and that the β enzyme can be induced by chronic DNA damage. - 79-6191 Mutagenesis by Cytostatic Alkylating Agents in Yeast Strains of Differing Repair Capacities. (Eng) Ruhland, A. (Arbeitsgruppe Mikrobengenetik im Fachbereich Biologie, Johann Wolfgang Goethe-Universität, Robert-Mayer-

Strasse 7-9, 6000 Frankfurt am Main, W. Germany); Brendel, M. *Genetics* 92(1): 83-97; 1979.

Mutation induction by several cytostatic alkylating agents, including nitrogen mustard and its analogs, was studied in depth. Specifically, the reversion of two nuclear ochre nonsense alleles and the cell inactivation induced by these mono-, bi-, and trifunctional alkylating agents and by UV light were investigated in stationary phase haploid cells of yeast strains with differing capacities for DNA repair. The ability to survive alkylation damage correlated with UV repair capacity, a UV-resistant, UV-mutable strain (*RAD REV*) being least sensitive and a UV-sensitive, UV-nonmutable strain (*rad1 rev3*) being most sensitive. The mutagenicity of the alkylating agents was highest in the former and abolished in the latter strain. Deficiency in excision repair (*rad1 rad2*) or in the *RAD18* function did not lead to enhanced mutability. Mutagenesis by the various agents was characterized by a common pattern of induction of locus-specific revertants and suppressor mutants. Induction kinetics were mostly linear, but UV-induced reversion in the *RAD REV* strain followed higher-than-linear (probably "quadratic") kinetics. The alkylating agent cyclophosphamide, usually considered inactive without metabolic conversion, reduced colony-forming ability and induced revertants in a manner similar, but not identical, to that of the other chemicals tested. These findings support the concept of mutagenesis by misrepair after alkylation, which can be distinguished from the mechanism of UV-induced reversion, in spite of their common features. (53 refs)

- 79-6192 Protein Synthesis Inhibition Induced by Dimethylnitrosamine and Diethylnitrosamine on Isolated Rat Hepatocytes. (Eng) Mattei, E. (Biophysical Lab., Inst. Regina Elena Cancer Res., 291, viale Regina Elena, I-00161 Rome, Italy); Delpino, A.; Ferrini, U. *Experientia* 35(9): 1213-1215; 1979.

Isolated hepatocytes from male Sprague-Dawley rats were used to study the inhibition of protein synthesis by dimethylnitrosamine (DMN) and diethylnitrosamine (DENA). Exposure of the cells to high doses of DMN or DENA did not appear to modify the energetic state of the hepatocytes or the leakage of lactic dehydrogenase from the cells. Treatment with either nitrosamine resulted in a definite dose-dependent inhibition of the incorporation of labeled amino acids into acid-soluble material, the inhibition caused by DENA being about 5x greater than that caused by similar concentrations of DMN. After exposure to toxic doses of the two nitrosamines, the inhibited cells progressively recovered their ability to synthesize proteins. The restoration of protein synthetic capability was greater and more rapid after exposure to DENA than after exposure to DMN. (13 refs)

- 79-6193 Effects of Discontinuation of Chronic Feeding of Diethylnitrosamine on the Development of Hepatomas in Adult Rats. (Eng) Barbason, H. (Laboratoire d'Anatomie Pathologique, Université de Liège au Sart-Tilman, 4000 Liège, Belgium); Smoliar, V.; Fridman-Manduzio, A.; Betz, E. H. *Br J Cancer* 40(2): 260-267; 1979.

The effects of discontinuation of chronic feeding of diethylnitrosamine (DENA) on the development of hepatomas in adult male Wistar rats were investigated. The rats were fed 20 mg/kg/day DENA continuously or for periods ranging from 1 to 10 wk. Survival correlated inversely with the duration of car-

CHEMICAL CARCINOGENESIS

cinogen feeding. Less than 4 wk of DENA feeding produced only preneoplastic foci that persisted indefinitely; 4 wk were found to be necessary for the transformation of preneoplastic lesions into liver cancers; after 6 wk, the incidence of hepatomas was 100%. Hepatocarcinogenesis appeared to be identical whether DENA was fed for 8 wk or continuously, up to the time of death. It is suggested that animals treated for <1 mo never developed hepatomas because the normal homeostatic regulation of cell division and function persisting during this first step prevents the growth of foci and their further malignant transformation. Feeding of DENA for >1 mo progressively and irreversibly disturbs this cell control and could, therefore, allow the transformation of foci into neoplastic nodules. DENA treatment beyond the second month has no further effect, perhaps because from this time on, the regulatory mechanism has already been lost and neoplastic development becomes autonomous. (26 refs)

- 79-6194 Induction of Foci of Altered γ -Glutamyltranspeptidase-positive Hepatocytes in Carcinogen-treated Rats Fed a Choline-deficient Diet. (Eng) Sells, M. A. (Dept. Pathology, Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261); Katyal, S. L.; Sell, S.; Shinzuka, H.; Lombardi, B. *Br J Cancer* 40(2): 274-283; 1979.

An attempt was made to determine whether, after exposure of rats to a chemical hepatocarcinogen, feeding a choline-deficient (CD) diet would promote the proliferation of initiated liver cells and the evolution of these cells to foci of altered γ -glutamyltranspeptidase (GGT)-positive hepatocytes. Diethylnitrosamine (DEN), in single doses of 15-150 mg/kg, was injected into intact male Sprague-Dawley rats or rats that had been partially hepatectomized (PH) 18 hr previously. The animals were then fed either a CD or a choline-supplemented (CS) diet for 2-8 wk. Emergence of foci of altered GGT+ hepatocytes was studied by histological and histochemical techniques. Varying numbers of foci developed in the liver of all rats fed the CD diet. The number of foci induced was larger in PH rats than in intact rats. Foci developed in none of the livers of rats fed the CS diet, except in one experiment in which 30 mg/kg DEN was injected into PH rats. In all cases, foci of altered GGT+ hepatocytes were shown to be α -fetoprotein-negative after immunofluorescence staining of liver sections. It is concluded that feeding a CD diet exerts a strong promoting action on the proliferation and further evolution of liver cells initiated by a chemical carcinogen, providing the basis for a new and efficient procedure for the induction of foci of altered hepatocytes in rat liver. (20 refs)

- 79-6195 Carcinogenesis in Tissue Culture 30: Malignant Transformation of Normal Rat Liver Cells Treated with Diethylnitrosamine in Tissue Culture with Special Reference to the Differential Effects of Cytochalasin B on Various Cells with and without Tumorigenicity. (Eng) Katsuta, H. (Japanese Res. Center of Tissue Culture, Dokkyo Univ. Sch. Medicine, Mibu, Tochigi 321-02, Japan); Takaoka, T. *Jpn J Exp Med* 49(3): 187-198; 1979.

Liver tissue from a 14-day-old female F31 rat (inbred strain JAR-2) was cultured for 3 wk and then treated with diethylnitrosamine (DEN: 50 or 100 μ g/ml) for 7 days. After 22 mo of culture, cells were back-transplanted sc into the backs of 4-wk-old F39 and F43 JAR-2 rats (4×10^7 cells/rat). Tumors developed at the inoculation site in every rat; tumors enlarged within 2 mo and caused death in some cases. Metastatic foci, which were histologically diagnosed as

hepatomas, were found in the lung. Chromosome analysis at 5 mo of culture showed that the mode of chromosome numbers in the cells treated with 100 μ g/ml DEN decreased from 42 to 40 and to a triploid range after 21 mo. In cells treated with 50 μ g/ml DEN, the diploid number was maintained at 5 mo but had decreased to 40 by 21 mo. The effects of cytochalasin B were examined using cinemicrography in nine tumorigenic and nontumorigenic cell strains, treated with 1 μ g/ml cytochalasin B during mo 22 through 24. Multinucleated cells were detected in the malignant cell cultures, whereas binucleated cells were abundant in the nontumorigenic cultures. The results indicate that the differential effects of cytochalasin B on tumorigenic and nontumorigenic cells correlates well with the tumor forming capacity of the cells on back-transplantation. - 79-6196 Carcinogenic Effect of *N*-Nitroso(2-hydroxypropyl)(2-oxopropyl)amine, a Postulated Proximate Pancreatic Carcinogen in Syrian Hamsters. (Eng) Pour, P. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Wallcave, L.; Gingell, R.; Nagel, D.; Lawson, T.; Salmasi, S.; Tines, S. *Cancer Res* 39(10): 3828-3833; 1979.

The carcinogenic effect of *N*-nitroso(2-hydroxypropyl)(2-oxopropyl)amine (HPOP) in male and female Syrian golden hamsters was studied. The animals received weekly sc doses of HPOP for life in concentrations of 1/10, 1/20, or 1/40 of the LD₅₀. The LD₅₀ of HPOP was 406.1 mg/kg for females and 353.5 mg/kg for males. All but one HPOP-treated animal developed tumors of types other than those found in controls, and the animals receiving the highest dose died earlier than those treated with the lowest dose. The multiplicity of induced neoplasms seemed to increase at the lower doses because of prolonged survival. Pancreatic tumors appeared in 73%-93% of HPOP-treated hamsters, adenocarcinomas of ductular origin being more common in males than in females. Tumors larger than 5-8 mm were usually invasive and had metastasized to liver or lung. Tumors of the following sites also occurred in HPOP-treated hamsters: nasal cavities (7%-67% of treated animals), larynx-trachea (20%-53%), lungs (67%-93%), lips (0%-40%), forestomach (0%-20%), intestine (0%-20%), liver (0%-60%), gallbladder (13%-33%), kidneys (0%-40%), urinary bladder-urethra (0%-13%), vagina (87%-93%), blood vessels (0%-20%), harderian gland (13%-53%), flank organ (0%-33%), and other (0%-40%). The data suggest that HPOP may be the proximate pancreatic carcinogen following the administration of *N*-nitrosobis(2-hydroxy-propyl)amine or *N*-nitrosobis(2-oxopropyl)amine to hamsters. (26 refs)

- 79-6197 A New *N*-Nitroso Compound, *N*-3-Methylbutyl-*N*-1-methylacetonitrosamine, in Corn-Bread Inoculated with Fungi. (Eng) Lu, S. H. (Cancer Inst., Chinese Acad. Medical Sciences, Peking, China); Li, M. H.; Ji, C.; Wang, M.; Wang, Y.; Huang, L. *Scientia Sinica* 22(5): 601-607; 1979.

A new *N*-nitroso compound, *N*-1-methylacetonitrosamine (*N*-3-methylbutylnitrosamine (MAMBNA), was found in corn bread inoculated with common fungi such as *Fusarium moniliforme*, *Geotrichum candidum*, *Aspergillus terreus*, or *A. flavipes*, which are encountered in the food of Lin Xian County, Henan Province, China. The preliminary identification of this compound by thin-layer chromatography was confirmed by gas chromatography-mass spectrometry. Furthermore, the compound was synthesized and was shown by chemical analysis to be identical to the MAMB-

NA isolated from the corn bread extract. In addition to MAMBA-NA, dimethylnitrosamine, diethylnitrosamine and methylbenzyl nitrosamine were formed in the fungus-inoculated corn bread after an 8-day incubation and the addition of a small amount of sodium nitrite. The presence of precursor compounds for the formation of nitrosamines in moldy maize flour and their significance with respect to the etiology of esophageal cancer in high-risk areas are surveyed. (9 refs)

- 79-6198 Potent Mutagenicity of Urethan (Ethyl Carbamate) Gas in *Drosophila melanogaster*. (Eng) Nomura, T. (Dept. Medical Genetics, Univ. Wisconsin, Madison, WI 53706). *Cancer Res* 39(10): 4224-4227; 1979.

The frequency of gene mutation and translocation induced by urethan (ethyl carbamate) was tested in *Drosophila melanogaster*, and the type of DNA damage produced was investigated. Exposure of spermatozoa to urethan gas induced a high frequency of X-linked recessive lethal mutations detected by the Muller-5 technique, and a clear dose-response was observed. Mutagenic activity of urethan gas on mature spermatozoa following 1.5 hr (2.4% mutations/chromosome) and 5.5 hr (5.5%) of exposure was approx equal to that induced by 1,000 rads (2.3%) and 2,000 rads (5.2%) of γ -radiation. A significant yield of mutations (1.2%) was also seen when germ cells were treated with urethan for 5.5 hr in the spermatogonial stage. Exposure of spermatozoa to urethan gas did not induce a significant yield of translocations, even when the treated sperm was stored in females for more than 10 days; in contrast, γ irradiation, which produced a comparable frequency of X-linked recessive lethal mutations, induced translocations with high frequency. Thus, urethan can barely induce translocation in *Drosophila* germ cells but can strongly induce point mutation. This may be the major cause for the lack of dominant lethals. Mature spermatozoa were exposed to mutagens and eggs were exposed to caffeine at immature stages when eggs are permeable. X-linked recessive lethal mutations induced by 3.5 hr exposure to urethan gas were not reduced by caffeine feeding to females at a low dose (0.5 mg/ml) but significantly reduced at the 5% level by caffeine feeding at a high dose (2.0 mg/ml). When mature spermatozoa were exposed to urethan gas for a longer period (5.5 hr), urethan-induced mutations were slightly reduced by a high dose (2.0 mg/ml) of caffeine, but the difference was not significant. The patterns of caffeine effects on urethan-initiated mutagenesis in *Drosophila* are similar to those of UV- or 4-nitroquinoline 1-oxide-initiated mutagenesis in *Escherichia coli*. (33 refs)

- 79-6199 Mutagenic Activity of Thiram in Ames Tester Strains of *Salmonella Typhimurium*. (Eng) Zdzienicka, M. (Dept. Biochemistry, Warsaw Medical Sch., Banacha 1, 02-097 Warsaw, Poland); Zielenska, M.; Tudek, B.; Szymczyk, T. *Mutat Res* 68(1): 9-13; 1979.

The mutagenic activity of thiram (varying doses, up to 200 μ g/plate) was investigated in 4 histidine-requiring strains of *Salmonella typhimurium* (TA1535, TA100, TA1538, TA98) with and without activation by liver microsomes. In strains TA1535 and TA100, thiram induced mutations without metabolic activation. The presence of rat-liver microsome fraction, cysteine, or glutathione abolished its mutagenic activity in these strains. In contrast, thiram requires metabolic activation for the expression of its mutagenic activity in TA1538 and TA98 strains. The compounds containing the sulfhydryl group abolished mutagenic activity of thiram in these strains also. (10 refs)

- 79-6200 Effect of the Duration of Retinyl Acetate Feeding on Inhibition of 1-Methyl-1-nitrosourea-induced Mammary Carcinogenesis in the Rat. (Eng) Thompson, H. J. (Dept. Home Economics, Pettee Hall, Univ. New Hampshire, Durham, NH 03824); Becci, P. J.; Brown, C. C.; Moon, R. C. *Cancer Res* 39(10): 3977-3980; 1979.

A study was carried out to determine whether continuous treatment is necessary to sustain the inhibition of mammary tumorigenesis produced by retinoid. Female Sprague-Dawley rats received iv injections of 1-methyl-1-nitrosourea (MNU) (50 mg/kg body wt) at 50 and 57 days of age. The animals began receiving a placebo diet or a diet supplemented with retinyl acetate (323 mg/kg diet) 10 days after the first carcinogen injection. Retinoid treatment was either discontinued 60 days after the first injection or continued until day 182 after injection. Retinoid treatment between 10 and 60 days after the first MNU injection prolonged the cancer latency and reduced the av number of cancers per rat, compared with that in controls. Continuation or cessation of retinoid treatment in 60-day tumor-bearing rats had no effect on the time of appearance of additional cancers. In 60-day tumor-free rats, continuation of retinoid treatment prolonged cancer latency in comparison with either 60-day tumor-free rats changed to placebo or rats continuously treated with placebo. The discontinuation of retinoid treatment resulted in a rapid increase in the appearance of cancers; at the termination of the study, the av number of cancers per rat was similar to that in animals fed only the placebo. The data indicate that some rats are more responsive to retinoid treatment than others. Retinoid treatment apparently prevents the progression of early neoplastic lesions, and continuous daily administration appears to be necessary to sustain the protective effect. (10 refs)

- 79-6201 Biochemical Analysis of Experimental Tumor Tissues of the Rat Brain Induced by Ethylnitrosourea. (Jpn) Matsumoto, M. (Second Dept. Surgery, Toho Univ. Sch. Medicine, 6-11-1 Ohmorinishi, Ohta-ku, Tokyo 143, Japan). *Nihon Geka Hokan* 48(4): 459-470; 1979.

A biochemical analysis of the experimentally induced brain tumors in the offspring of female Sprague-Dawley rats injected intraabdominally with ethylnitrosourea (EN) was made in comparison to normal tissue and gliosis tissue from the same rats. Female rats were injected on day 14 of gestation with 50 mg/kg EN, and the offspring were isolated after 120 days and observed. The rate of induction of nervous system tumors was 93%. Tumors were first observed 200 days after birth and developed in the cerebrum in 74.3%, brain stem in 10.5%, and spinal chord in 15.2% of the rats. Mixed gliomas were found in approx 44% of the rats, oligodendroglioma in approx 28%, anaplastic glioma in approx 28%; and 1 rat had an ependymoma-like tumor. The tissue protein content of gliosis tissue and tumor tissue was within the range of controls. The RNA and DNA content in the gliosis tissue was about the same as controls at 1 wk and increased a little by 1 mo, while the RNA/DNA ratio decreased at 1 mo. The RNA and DNA content in the glioma tissue increased, and the RNA/DNA ratio decreased greatly (0.81) compared to gliosis and normal tissue. At 1 wk, the free amino acid level in the gliosis tissue was comparatively normal, and aspartic acid and γ -aminobutyric acid (GABA) levels were low; all three decreased at 1 mo. In the experimental glioma tissue, the aspartic acid, glutamic acid, and GABA levels were low while the glutamine, glycine, and alanine levels were high. In 50% of the glioma tissue specimens, the measurement of GABA was not possible. At 1 wk, the lysosomal enzymes (β -glucuronidase and acid phosphatase) were higher than

CHEMICAL CARCINOGENESIS

normal in gliosis and glioma tissues (β -glucuronidase 15 x normal in glioma) but returned to normal levels by 1 mo. (33 refs)

- 79-6202 The Mutagenicity of Nitrosamides in *Salmonella typhimurium*. (Eng) Lijinsky, W. (Chemical Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Andrews, A. W. *Mutat Res* 68(1): 1-8; 1979.

Thirty-four nitrosamides (10 nitrosoalkylcarbamates, 2 nitrosoalkylnitroguanidines, 12 nitrosoalkylureas, 6 substituted nitrosoalkylureas, and 4 cyclic nitrosoalkylureas) were tested for mutagenicity in *Salmonella typhimurium*. All were direct-acting and mutagenic in strain TA1535, with the exception of nitrosophenylurea; its mutagenicity was best demonstrated in strain TA1537. Incubation with a rat-liver microsomal preparation inactivated the nitrosamide and either decreased mutagenicity or left it unaffected. Differences in mutagenic potency among nitrosamides within the same group was in many instances very large and may be partly explained by steric and electronic effects and by the different solubilities of the various compounds. The results show that the mechanism of mutagenesis in bacteria, even by direct-acting alkyl nitrosamides, is complicated. (10 refs)

- 79-6203 Luminal Plasma Membrane Organization in Rat Urinary Bladder Urothelium After Direct Exposure In Vivo to N-Methyl-N-nitrosourea. (Eng) Hainau, B. (Dept. Pathology, Bispebjerg Hosp., Bispebjerg Bakke 23, DK-2400 Copenhagen N.V., Denmark). *Cancer Res* 39(9): 3757-3762; 1979.

The fate of the specialized luminal plasma membrane and junctional complex was analyzed after exposure of rat urothelium to N-methyl-N-nitrosourea (MNU). Adult female Wistar rat urinary bladders were exposed to MNU in vivo (two 1-mg doses instilled in the bladder at an interval of 4 wk). After 12 wk, urothelial hyperplasia was established. Ultrastructural changes in the luminal plasma membrane were studied by thin-sectioning and freeze-fracturing techniques. The mosaic pattern that is a unique characteristic of normal luminal plasma membrane and cytoplasmic vesicles disappeared. The plasma membrane of the transformed urothelium was indistinguishable from undifferentiated membranes in the following respects: thickness; apparent symmetry in cross-section; and distribution of intramembranous particles. Zonulae occludens became permeable to colloidal lanthanum and appeared disassembled, and desmosomes developed concomitantly. These membrane changes indicate that there is increased permeability and less adaptability of urothelial function to mechanical stress caused by bladder volume changes. The increased desmosome formation indicates that squamous metaplasia is a feature of early malignant transformation of the urothelium. It is proposed that MNU alters the plasma membrane assembly and specialization. (29 refs)

- 79-6204 Effect of Dietary Alfalfa, Pectin, and Wheat Bran on Azoxymethane- or Methyl nitrosourea-induced Colon Carcinogenesis in F344 Rats. (Eng) Watanabe, K. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595); Reddy, B. S.; Weisburger, J. H.; Kritchinsky, D. *J Natl Cancer Inst* 63(1): 141-145; 1979.

The modifying effect of dietary alfalfa, pectin, and wheat bran on azoxymethane (AOM)- and methyl nitrosourea (MNU)-induced colon carcinogenesis was studied in female inbred F344 rats. Weanling rats were fed semipurified diets containing 0% or 15% alfalfa, pectin, or wheat bran. Experimental and control diets also contained 5% alphacel, a cellulose-type nonnutritive fiber, as a source of fiber and 20% corn oil. At 7 wk of age, all animals except controls were given AOM sc at a dose rate of 8 mg/kg/wk for 10 wk or MNU intrarectally at a dose rate of 2 mg/rat twice a week for 3 wk. The AOM-treated group was autopsied 40 wk and the MNU-treated group 30 wk after the first injection of the carcinogen. No tumors were observed in the colon or other organs of untreated rats fed the various diets. Animals fed the alfalfa diet and treated with MNU had a higher incidence of colon tumors than did those fed the control diet or the diets containing pectin or wheat bran. The incidence of MNU-induced colon tumors did not differ between the animals fed the control diet or the diets containing pectin or wheat bran. However, the incidence of AOM-induced colon tumors in rats fed diets containing pectin or wheat bran was lower than that in rats fed the control diet or the alfalfa diet. These results indicate that the effect of fiber in colon carcinogenesis depends on the type of fiber and, possibly, the fiber's mode of action. (27 refs)

- 79-6205 The Relation Between Reaction Kinetics and Mutagenic Action of Mono-functional Alkylating Agents in Higher Eukaryotic Systems. II. Total and Partial Sex-Chromosome Loss in *Drosophila*. (Eng) Vogel, E. (Dept. Radiation Genetics and Chemical Mutagenesis, State Univ. Leiden, Sylvius Labs., Wassenaarseweg 72, Leiden, Netherlands); Nataraajan, A. T. *Mutat Res* 62(1): 101-123; 1979.

The connection between the primary alkylation patterns and genetic activities of eight monofunctional alkylating agents (AA) was studied using spermatozoa and spermatids of treated *R 1(2), Y B/B⁺ Y y⁺* *Drosophila* males. Ability to produce chromosome aberrations was assessed based on the induction of ring X loss, Y-chromosome loss, and Y rearrangements. The ability to cause chromosomal losses and produce translocations decreased in the sequence methyl methanesulfonate (MMS) = dimethyl sulfate (DMS) > N-methyl-N-nitrosourea (MNU) = N-nitrosodimethylamine (DMA) > ethyl methanesulfonate (EMS) > isopropyl methanesulfonate (iPMS) > N-ethyl-N-nitrosourea (ENU) = N-nitrosodiethylamine (DEN). The low frequencies of Y-chromosome rearrangements made any meaningful comparison between these AA impossible. With MNU, DMN, EMS, MMS, and DMS, a time-dependent increase in the frequencies of ring X losses (storage effect) was observed. Mature spermatozoa tended to be more resistant to the induction of breaks by MNU, DMA, EMS, and MMS. With all AA, a reduced rate of survival of X-bearing sperm was seen after treatment with mutagen. However, there was no apparent quantitative relationship between the shift in the sex ratios and the yield of chromosome aberrations. It is concluded that the differences between these AA in their selectivity for numerous nucleophiles of DNA (indicated by their Swain-Scott *s* values) account for most of the diversity in their genetic effectiveness. Methylation was more effective than ethylation in breaking chromosomes. (20 refs)

- 79-6206 Mutagenicity of Methyl-, Ethyl-, Propyl- and Butylnitrosourea Towards *Escherichia coli* WP2 Strains with Varying DNA Repair Capabilities. (Eng) Garner, R. C. (Cancer Res. Unit, Univ. York, Heslington, York YO1 5DD,

England); Pickering, C.; Martin, C. N. *Chem Biol Interact* 26(2): 197-205; 1979.

The toxicity and mutagenicity of methyl- (MNUA), ethyl- (ENUA), propyl- (PNUA), and butylnitrosourea (BNUA) to *Escherichia coli* WP2 and some of its repair-deficient derivatives were tested in a liquid suspension assay. A comparison of survival rates after nitrosourea exposure between WP2 and WP2 *uvrA* showed no difference between the two strains but a consistent difference in potency between the various nitrosoureas studied. Toxicity increased in the order MNUA < PNUA < ENUA < BNUA. ENUA and PNUA induced a greater number of *trp*⁺ revertants in both strains than did MNUA and BNUA, particularly at low survival rates. None of these differences in biological potency could be accounted for by differences in rates of hydrolysis. ENUA, PNUA, and BNUA were nonmutagenic toward WP2 *lexA*, WP2 *recA*, and WP2 *urA lexA*, whereas MNUA did induce mutations. Ethyl methanesulfonate was able to mutate WP2 *lexA*. (23 refs)

79-6207 Correlation of Biochemical and Morphological Changes Induced by Chemical Injury to the Lung. (Eng) Stewart, B. W. (Sch. Pathology, Univ. New South Wales, P.O. Box 1, Kensington, New South Wales 2033, Australia); Le Mesurier, S. M.; Lykke, A. W. *Chem Biol Interact* 26(3): 321-338; 1979.

Biochemical and morphological changes in female Wistar rat pulmonary alveolar parenchyma induced by N-nitrosomethylurethane (NNMU: 4 mg/kg, iv), 3-methylcholanthrene (MCA: 50 mg/kg, intratracheally), carbon tetrachloride (53,000 mg/m³, 30 min/day for ≤ 15 days, by inhalation), trichloroethylene (TCE: 48,500 mg/m³, 30 min/day for ≤ 15 days), or gasoline vapor (GV: by inhalation) were studied. Single doses of NNMU or MCA inhibited the incorporation of [¹⁴C]orotate into lung RNA 1-3 days after treatment. Daily exposure to CCl₄ to TCE vapor caused a less marked reduction in orotate incorporation, and GV had no significant effect on orotate incorporation. MCA toxicity was characterized by cytoplasmic changes including disruption of surfactant lamellae of Type 2 pneumocytes and variable degenerative changes in Type 1 pneumocytes. At 8-10 days after treatment, the morphological evidence of hypertrophy/hyperplasia and transformation of Type 2 pneumocytes correlated well with biochemical evidence of stimulated [³H]thymidine incorporation. CCl₄ and TCE vapors produced milder changes, including occasional degenerative changes in Type 1 pneumocytes, reduced numbers of surfactant lamella in Type 2 pneumocytes, and no changes in [³H]thymidine incorporation. All chemicals caused a marked and reproducible reduction in secretion of pulmonary surfactant, as determined by endobronchial lavage. Reduced recovery of surfactant was detected after 5 days of solvent inhalation, but no further changes resulted from another 10 days exposure. (32 refs)

79-6208 Effects of Dietary Administration of Chenodeoxycholic Acid on N-methyl-N-nitrosourea-induced Colon Cancer in Rats. (Eng) Sarwal, A. N. (New York Univ. Medical Center, New York, NY); Cohen, B. I.; Raicht, R. F.; Takahashi, M.; Fazzini, E. *Biochim Biophys Acta* 574(3): 423-432; 1979.

The effects of dietary chenodeoxycholic acid (CA: 0.2% by wt of normal diet) upon N-methyl-N-nitrosourea (MNU)-induced colonic tumors and on fecal sterol patterns were studied in male CD

Fisher rats. At 6 wk of age, MNU administration was begun (2 mg/rat intrarectally on days 1, 4, 8 and 11). Twenty-two of 45 rats fed a normal diet had developed colonic tumors at the time of sacrifice (28 wk after the first MNU dose), whereas 26/42 rats fed a CA-supplemented diet and given MNU developed tumors (p < 0.2). Most lesions were adenomatous polyps with some adenocarcinoma in situ; nine polyploid lesions demonstrated invasive carcinomas. Analysis of stools by gas-liquid chromatography-mass spectroscopy showed fecal neutral sterol levels to be elevated in the MNU-treated groups (p < 0.05), irrespective of diet. Feeding the CA diet increased fecal bile acid concentration from 4 mg/g stool in untreated controls to 10.3 mg/g in animals receiving CA (p < 0.025); MNU administration did not have this effect, nor was there evidence that it interacted with the CA diet. Isolithocholic acid was 21% of the total 3-monohydroxy bile acids in rats given CA. In animals fed control diets, isobile acid levels were negligible. The small increase (1 mg/g stool) in secondary bile acid (deoxycholic acid and lithocholic acid) levels may be the reason that CA diets do not greatly increase the incidence of MNU-induced colonic cancer, as do diets containing cholic acid. The profile of fecal bile acids of rats fed a CA diet suggests that the ability of rats to 6- and 7-hydroxylate bile acids may block the promoting effect of dietary CA upon MNU-induced colonic cancer. 79-6209 The Relation Between Reaction Kinetics and Mutagenic Action of Mono-functional Alkylating Agents in Higher Eukaryotic Systems. I. Recessive Lethal Mutations and Translocations in *Drosophila*. (Eng) Vogel, E. (Dept. Radiation Genetics and Chemical Mutagenesis, State Univ. Leiden, Sylvius Labs., Wassenaarseweg 72, Leiden, Netherlands); Natarajan, A. T. *Mutat Res* 62(1): 51-100; 1979.

The relationship in *Drosophila* males between the chemical reaction patterns of monofunctional alkylating agents (AA) and their biological effectiveness was studied. The ability to break chromosomes decreased in the sequence methyl methanesulfonate (MMS) > dimethyl sulfate (DMS), N-methyl-N-nitrosourea (MNU) > N-nitrosodimethylamine (DMN) > ethyl methanesulfonate (EMS) > isopropyl methanesulfonate (iPMS) > N-ethyl-N-nitrosourea (ENU) = N-nitrosodiethylamine (DEN). When mutagenic effectiveness was determined on the basis of the ratio of the exposure condition producing 4% recessive lethals to the LD₅₀, the sequence was ENU > EMS > iPMS, MNU > MMS = DMS. EMS was slightly less effective in the translocation test and less cytotoxic but more mutagenic in the recessive-lethal test than would be expected based on its Swain-Scott *s* value. This was taken as an indication of the influence on biological effectiveness of factors other than the *s* value, eg, methylation vs ethylation and the lipid:water partition ratio. For those AA that were clearly active in the translocation test, a delayed formation of exchanges was observed. Thus, storage experiments in *Drosophila* are necessary to detect this type of rearrangement by AA. The apparent link between the ability of AA to induce chromosome breakage and to produce delayed mutations indicated the significance of nucleophiles with high *n* values for the initiation of either event. The data indicate that two variables have major significance in determining the quality and frequency of genetic damage of AA in *Drosophila*: dose and reaction pattern (site of alkylation). The molecular events that characterize the action of ENU and DEN on DNA, ie, O-alkylation (in particular, phosphotriester formation), are not critical for the processes leading to chromosome breakage. 79-6210 N-Ethyl-N-Nitrosourea-induced Spinal Tumors in an Inbred Strain of W Albino Rats. (Eng) Pfaffenroth,

M. J. (Dept. Biological Sciences, Lilly Hall Life Sciences, Purdue Univ., West Lafayette, IN 47907); Das, G. D. *J Natl Cancer Inst* 63(3): 647-650; 1979.

The incidence of spinal tumors developing in an inbred strain of W albino rats exposed prenatally to N-ethyl-N-nitrosourea (ENU: 60 mg/kg) on one of days 14-21 of gestation or were given a single postnatal dose (0.2 mg/animal) directly into the cerebellum 6 or 11 days after birth was investigated. Twenty-nine of 34 rats that had been exposed to ENU prenatally and 6/15 rats exposed postnatally developed one or more CNS tumors. Spinal tumors were detected in 14 animals exposed prenatally and 4 exposed postnatally to ENU. In another study, 23/25 animals exposed prenatally to a single dose of 60 mg ENU/kg on day 20 of gestation developed spinal cord tumors. These tumors included relatively pure oligodendrogliomas, astrocytomas, and mixed gliomas. The results suggest that this rat strain has a high susceptibility to the induction of tumors in the spinal cord by ENU and would be a good neural tumor research model. (13 refs)

79-6211 Development of Second Malignancies in Rats After Cure of Acute Leukemia L 5222 by Single Doses of 2-Chloroethylnitrosoureas. (Eng) Zeller, W. J. (Inst. Toxicology and Chemotherapy, German Cancer Res. Center, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Schmahl, D. *J Cancer Res Clin Oncol* 95(1): 83-86; 1979.

The development of secondary malignant tumors in 9/79 BD IX rats cured of rat leukemia L5222 by single doses of 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) or 1-(2-hydroxyethyl)-3-(2-chloroethyl)-3-nitrosourea (HECNU) is reported. The drugs (6.3-12.5 mg/kg, ip) were administered late in the course of leukemia development. Malignant secondary tumors developed in 4/36 rats given BCNU and 5/43 rats given HECNU. The tumors included an intraabdominal fibrosarcoma, a meningeal sarcoma, an oligodendroglioma of the brain, an endocardial sarcoma, an intrathoracic adenocarcinoma (metastatic), an adrenal cortical carcinoma, an ovarian carcinoma, a malignant neurinoma of the cauda equina, and a cholangiocellular carcinoma. These secondary malignancies were attributed to nitrosourea therapy and the results suggest that a detailed investigation of the carcinogenicities of clinically used 2-chloroethylnitrosamines is necessary. (9 refs)

79-6212 The Mutagenicity of Nitrosopyrrolidine is Related to Its Metabolism. (Eng) Hecker, L. I. (Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Elespuru, R. K.; Farrelly, J. G. *Mutat Res* 62(2): 213-220; 1979.

Various cell fractions from rat liver were tested for their ability to convert nitrosopyrrolidine (NO-PYR, 5-25 millimolar) to products which were mutagenic to *Escherichia coli* in liquid-incubation assays. Microsomes alone produced only a small number of *tyr*+ revertants (approx 40/10⁸ survivors), while the S₁₀₀ supernatant produced none at all. However, the S₈ fraction or combinations of microsomes and the S₁₀₀ supernatant yielded 300-400 *tyr*+ revertants/10⁸ survivors. Neither products of the microsomal nor of the microsome + supernatant reactions were mutagenic in the absence or presence of cellular fractions. These results suggest that bacterial mutagens are formed during the microsomal metabolism of NO-PYR to 2-hydroxytetrahydrofuran by α -hydroxylation, but not during the metabolism of 2-hydroxytetrahydrofuran by the S₁₀₀ supernatant enzymes. Possible roles of the supernatant en-

zymes in the formation of mutagenic intermediates during the initial α -hydroxylation of NO-PYR are discussed. (29 refs)

79-6213 Dominant Lethal Assay of Some Hair-Dye Components in Random-Bred Male Rats. (Eng) Sheu, C. J. (Genetics Toxicology Branch, Div. Toxicology, Food and Drug Admin., Washington, DC 20204); Green, S. *Mutat Res* 68(1): 85-98; 1979.

Male rats were exposed to maximally tolerated doses of five hair-dye components in a dominant lethal test. Each component was tested at 3 dosage levels with 15 random-bred male rats per level. The highest dose, selected on the basis of subacute toxicity testing, generally reduced weight gains without being lethal. Freshly prepared solutions were injected ip at 1 ml/kg 3x/wk for 10 wk. Rats injected with dimethylsulfoxide and triethylenemelamine served as solvent and positive controls, respectively. A majority of rats survived the treatment at the levels tested and were mated to two virgin females each per wk for 2 wk. The females were sacrificed at midterm of pregnancy and examined for live and dead implants. Dominant lethality was evaluated on the basis of 4 criteria: dead implants per pregnant female, dead implants per total implants, proportion of females with one or more dead implants, and proportion of females with two or more dead implants. 2-Nitro-*p*-phenylenediamine, 2,4-diaminoanisole sulfate, and 2,5-diaminoanisole sulfate produced negative responses, whereas *m*-phenylenediamine and 4-nitro-*o*-phenylenediamine induced weak dominant lethality in the first trial. On retesting these weakly positive components, both *m*-phenylenediamine and 4-nitro-*o*-phenylenediamine produced negative responses. (11 refs)

79-6214 Carcinogenesis in Rat Esophagus by Intraperitoneal Injection of Different Doses of Methyl-n-amylnitrosamine. (Eng) Bulay, O. (Ankara Univ., Tip Fakultesi Patoloji Kursusu, Morfologi, Sihhiye, Ankara, Turkey); Mirvish, S. S. *Cancer Res* 39(9): 3644-3646; 1979.

The carcinogenicity of methyl-n-amylnitrosamine (MNAN) in MRC-Wistar rats was determined after ip injection on a variety of dose schedules. After 6 weekly MNAN injections of 25 mg/kg or 12 weekly injections of 12.5 or 25 mg/kg, the incidence of esophageal squamous cell papillomas was 85%-100% and that of esophageal squamous cell carcinomas was 40%-65%. With 12 injections, the mean survival time was 25-31 wk. Treatment with one or two doses of 50 mg/kg produced a lower incidence (<20%) of esophageal tumors and a longer survival time of 67-77 wk. One 85-mg/kg injection caused esophageal carcinomas in 5/7 rats. The treated groups also had squamous cell papillomas and carcinomas in the nasal cavity (up to 50% incidence) and trachea (up to 30% incidence). Hence, a 6- or 12-wk treatment schedule was adequate for inducing esophageal tumors and could be used for studies of agents modifying esophageal tumor induction by MNAN. (10 refs)

79-6215 Neoplastic and Preneoplastic Lesions in Rats after Oral Administration of a Single Dose of N-Nitrosomorpholine. (Ger) Bannasch, P. (Abteilung fur Cytopathologie, Institut fur Experimentelle Pathologie, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900

Heidelberg, W. Germany); Mayer, D.; Krech, R. *J Cancer Res Clin Oncol* 94(3): 233-248; 1979.

Tumor development was studied in 62 male Sprague-Dawley rats given a single po dose of N-nitrosomorpholine (NNM: 320 mg/kg). This treatment resulted in the development of neoplastic and preneoplastic changes in different organs, especially the liver and kidney. After a lag period of 4 wk, nearly all experimental animals developed preneoplastic (clear cell, acidophilic, basophilic, mixed cell) foci in the liver parenchyma. Small neoplastic nodules were found sporadically in the liver as early as 4 wk after the beginning of the experiment. After a lag period of 1-2 yr, 4/13 rats showed multiple neoplastic hepatic nodules, and 1 animal had a hepatocellular carcinoma. Mucous cholangiofibroses and cystic cholangiomas occurred in some experimental animals. After long lag periods, large cholangiofibromas were found in two experimental animals. One or two years after carcinogen administration, many animals developed epithelial (clear cell, acidophilic, chromophobic, basophilic, oncocyctic) kidney tumors, which were often cystic. Pathologically changed (clear cell, chromophobic, basophilic, oncocyctic) tubules are regarded to be precursors of epithelial tumors. The altered tubules appeared for the first time about 6 mo after carcinogen administration. In addition to multiple hepatic and renal cysts, two animals developed pancreatic cysts. In addition, two mesenchymal kidney tumors, one malignant neurinoma, two subcutaneous fibromas, one fibroadenoma, and one squamous cell carcinoma of the skin were observed. (43 refs)

- 79-6216 Experimental Induction of Hepatomas, Mammary Tumors, and Other Tumors with Metronidazole in Noninbred Sas:MRC(W1)BR Rats. (Eng) Rustia, M. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42d St. and Dewey Ave., Omaha, NE 68105); Shubik, P. *J Natl Cancer Inst* 63(3): 863-868; 1979.

Metronidazole was tested for carcinogenicity in noninbred Sas:MRC(W1)BR rats. Three groups received the drug for life at dose levels of 0.6%, 0.3%, and 0.06% in a powdered diet. The incidences of mammary tumors and hepatomas increased significantly ($p < 0.020$ and $p < 0.050$, respectively) among females given the highest dose, compared with controls. The rates of Leydig cell tumors of the testes and pituitary adenomas were increased ($p < 0.040$ for both) among males given the highest dose. These results, together with those obtained in other studies, suggest that metronidazole possesses a considerable carcinogenic potential. (34 refs)

- 79-6217 Lack of Evidence for Cancer Due to Use of Metronidazole. (Eng) Beard, C. M. (Dept. Medical Statistics and Epidemiology, Mayo Clinic, 200 First St. SW, Rochester, MN 55901); Noller, K. L.; O'Fallon, W. M.; Kurland, L. T.; Dockerty, M. B. *N Engl J Med* 301(10): 519-522; 1979.

The development of cancer was evaluated in 771 women who were treated for vaginal trichomoniasis with metronidazole (750 mg/day for 10 days) during 1960-1969. Forty cases of cancer were diagnosed in the metronidazole-exposed group during 8,267 person-yr of follow-up evaluation since exposure. Sixteen of these tumors were carcinoma in situ of the uterine cervix. At all other sites as a whole, the number of observed cancers (24) were not significantly higher than expected (21.7 based on the Connecticut Tumor Registry and 18.4 on the Third National Cancer Survey).

Analysis of the observed and expected number of cancers according to specific site showed that the observed number in all sites except the lungs was similar to the expected number. There were four cases of lung cancer compared to the expected 0.6, but the four patients were all smokers. The 11 deaths from cancer in this group were more than expected but not statistically significant. The number of carcinomas of the uterine cervix in patients with a history of trichomoniasis was greater than expected in women without such a history regardless of whether or not they were treated with metronidazole. These data suggest that an increase in cervical cancer may be caused by the underlying infection or some predisposing factor common to both diseases rather than by metronidazole treatment. (39 refs)

- 79-6218 Morphologic Changes of the Gastric Mucosa of Rats After Administration of N-Methyl-N'-Nitro-N-Nitrosoguanidine. Electron Microscopic Study. (Eng) Jakubovsky, J. (Res. Lab. Histochemistry, Komensky Univ., 884 24 Bratislava, Czechoslovakia); Brozman, M.; Zaviacic, M.; Duris, I.; Popperova, E. *Neoplasma* 26(1): 39-47; 1979.

The effects of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 83 mg/liter in drinking water for 8 wk) on the gastric mucosa were studied in 12 male Wistar rats. The nuclei of the undifferentiated, and to a lesser degree the differentiated epithelial cells were mostly round or oval and occasionally displayed a surface consisting of deep invaginations or intranuclear cytoplasmic pseudoinclusions containing different organelles. In such nuclei, disappearance of parts of the outer nuclear membranes was generally observed. Thin bands of peripheral condensed chromatin extended far into the peripheral cytoplasm; these bands were not surrounded by nuclear membranes. An increased amount of perichromatin and interchromatin granules was observed in the chromatin. The nuclear membranes contained predominantly irregular broad perinuclear cisterns; these were occasionally bridged by porous complexes, the number of which varied from one area to another. In the cytoplasm of differentiated epithelial cells, autophagous processes were observed, and in the undifferentiated neck cells, large amounts of polysomes and profiles of diversely deformed rough endoplasmic reticulum were seen. These cells showed marked proliferative activity. The changes described in the nuclei of the epithelial cells were also observed in the nuclei of some smooth muscle cells, fibrocytes, and eosinophils, where the nuclear material was localized below the cell surface and the cytoplasm was found within limited spaces. (24 refs)

- 79-6219 High Concentrations of Glutathione in Glandular Stomach: Possible Implications for Carcinogenesis. (Eng) Boyd, S. C. (Field Studies and Statistics Program, Div. Cancer Cause and Prevention, NCI, Bethesda, MD 20205); Sasame, H. A.; Boyd, M. R. *Science* 205(4410): 1010-1012; 1979.

The concentrations of reduced glutathione (GSH) in the glandular stomach of male Sprague-Dawley rats, measured in the late afternoon, was 7.23-8.26 mM, which is similar to that seen in the liver and exceeded that of all other tissues. Gastric GSH varied diurnally; concentrations were highest in the late afternoon and lowest at night and early morning. Starvation (48 hr), depletion of hepatic GSH by diethyl maleate (DEM) treatment, or stress by physical restraint for 4 hr in the cold caused marked decreases in GSH. Prior treatment of animals with cobaltous chloride caused a marked increase in gastric and hepatic GSH concentrations. The

CHEMICAL CARCINOGENESIS

resistance of the glandular gastric mucosa of laboratory rodents to carcinogens, such as the polyaromatic hydrocarbons (PAH), might be due to the relatively low GSH concentration in the squamous portions of the stomach, which are highly susceptible to PAH compounds, since GSH deactivates carcinogenic PAH metabolites. It is also possible that the high susceptibility of the glandular stomach to carcinogens such as N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) might be directly related to the high GSH content of that portion of the stomach, since a previous study showed that GSH strongly stimulates DNA alkylation by MNNG in vitro. (19 refs)

- 79-6220 Oncogenic Transformation in Epithelial Cell Lines Derived from Tracheal Explants Exposed In Vitro to N-Methyl-N'-nitro-N-nitrosoguanidine. (Eng) Steele, V. E. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Marchok, A. C.; Nettesheim, P. *Cancer Res* 39(10): 3805-3811; 1979.

To investigate oncogenic transformation of respiratory tract epithelium in vitro, tracheal explants from specific-pathogen-free Fischer 344 rats were exposed to N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 0, 0.001, 1.0, or 10.0 µg/ml medium) for 6 hr on days 3 and 6 of culture. Primary epithelial cell cultures, derived from 25/30 carcinogen-exposed explants, underwent a distinct morphological change after approx 160 days of culture. Only after this change could primary cell cultures be subcultured into cell lines. No cell lines could be established from control tissues. The tumorigenicity of the cell lines was determined after approx 10 or 20 passages by inoculation of 10⁶ cells into immunosuppressed syngeneic rats. The number of explants that yielded tumorigenic cell lines was 0, 5, 6, and 9, respectively, for groups of 10 animals exposed to 0, 0.001, 1.0, and 10.0 µg/ml MNNG. The av latency period between inoculation and tumor appearance was also dose-related; it was significantly shorter for cell lines in the group receiving 10 µg MNNG/ml (56 ± 21 days) than for cell lines in the group receiving 0.001 µg/ml (108 ± 13 days, p < 0.05). Either adenosquamous cell carcinomas or keratinizing squamous cell carcinomas were obtained from cell lines in all groups. Four cell lines in the group receiving 10 µg MNNG/ml and two cell lines in the group receiving 1 µg/ml formed tumors that metastasized to other organs. During culture, cell lines became increasingly malignant, as demonstrated by inoculation of some of the cell lines at successive passages; in all cases, tumor incidence increased and the latency period decreased with increasing passage number. The high frequency of transformation, the dose response, and the production of differentiated epithelial tumors achieved make this culture system a valuable tool for studying the oncogenic transformation of respiratory tract epithelium in vitro. (22 refs)

- 79-6221 Early Proliferative Changes in Rat Pyloric Mucosa Induced with N-Methyl-N'-Nitro-N-Nitrosoguanidine (MNNG). (Eng) Deschner, E. E. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Tamura, K.; Bralow, S. P. *Front Gastrointest Res* 4: 25-31; 1979.

The early proliferative changes occurring prior to and during gastric tumor formation were studied in random bred Wistar rats given N-methyl-N'-nitro-N-nitrosoguanidine (MNNG, 83 mg/liter) in the drinking water for 15 wk. After 10 wk of MNNG administration, the rats showed a downward shift in the distribution of the proliferative compartment in the pyloric mucosa. Histologically atypical pits lined with cuboidal mucous-depleted epithelial cells which demonstrated increased proliferative activity

were also observed at 10 wk. At 10 and 15 wk, the labeling indices of these pits were elevated two- to fivefold over control levels. Early invasive adenocarcinomas were noted at both 10 and 15 wk. Tumor cells actively penetrating the muscularis mucosa appeared to be more actively engaged in DNA synthesis than tumor cells confined within the mucosa. If the mechanism and development of gastric cancer in man are similar to those observed in this animal model, there is little hope for improving the 5-yr survival statistics. (8 refs)

- 79-6222 Sequential Histopathology and Cell Kinetic Changes in Rat Pyloric Mucosa During Gastric Carcinogenesis Induced by N-Methyl-N'-nitro-N-nitrosoguanidine. (Eng) Deschner, E. E. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Tamura, K.; Bralow, S. P. *J Natl Cancer Inst* 63(1): 171-179; 1979.

The effect of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 83 mg/liter drinking water) on the pyloric mucosa of male noninbred Wistar rats was followed. Autoradiographic studies were made of animals killed after 10, 15, 26, and 36 wk of treatment. In the normal-appearing mucosa of rats treated with MNNG for 10 wk, the number of epithelial cells per pit column was significantly increased over that in controls. Simultaneously, a shift in the major zone of epithelial cell proliferation was noted in the treated rats. Along with the formation of a longer pit in MNNG-treated rats, the greatest number of DNA-synthesizing cells was displaced from the middle third of the pit in a downward direction toward the muscularis mucosa. In addition, at this early experimental time period, pits lined with more immature, cuboidal, mucus-depleted cells were recognizable. These pits not only had higher labeling indices than normal-appearing pits of the same animals, but they also had a dual nature, with increased proliferative activity extending either upward to the luminal surface or further in a downward direction. Focal areas of cellular atypism, present by week 10 of treatment, had a three- to sevenfold greater DNA synthesis activity than that found in the normal-appearing mucosa of the same animal. A wide range of proliferative activity was found not only among invasive pyloric tumors within the same animal, but also within different areas of the same tumor. The mechanism for the formation of adenomas and invasive adenocarcinomas is believed to be related to the dual character of the hyperplastic pits. (25 refs)

- 79-6223 Effect of Aging on the Development of N-Methyl-N'-nitro-N-nitrosoguanidine-induced Gastric Cancer in Rats. (Eng) Kimura, M. (Dept. Surgery, 617-1, Takahayashi, Gunma Cancer Center, Ota, Gunma-ken 373, Japan); Fukuda, T.; Sato, K. *Gann* 70(4): 521-525; 1979

The effect of aging on the induction of N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) gastric carcinogenesis was studied in male Wistar rats. Three groups of rats, aged 6, 20, and 40 wk, were used. All groups received MNNG in the drinking water (83 mg/liter) for 30 wk. The gastrointestinal tumor incidences were 94.7%, 73.8% and 48.8% at 6, 20, and 40 wk of age, respectively; tumor incidence in the two older groups was significantly decreased (p < 0.01) compared with that in the youngest group. The incidence of glandular stomach adenocarcinomas was also significantly decreased (p < 0.01) in the younger groups (86.8%, 50%, and 39.4% in 6-, 20-, and 40-wk-old animals, respectively). The rate of MNNG intake per gram body wt was higher in the youngest group during the first 25 wk than in the 20-wk-old rats.

However, even when the dose was adjusted to that of the older rats, the tumor incidence was unaffected. It is concluded that aging may reduce the incidence of MNNG-induced gastric cancer in rats. (10 refs)

- 79-6224 Effects of Arginine Deprivation Upon Chromosome Aberrations, SCEs and Survival of CHO Cells Treated with Mutagenic Agents. (Eng) MacRae, W. D. (Environmental Carcinogenesis Unit., B.C. Cancer Res. Centre, Vancouver, B. C., Canada); MacKinnon, E. A.; Stich, H. F. *Mutat Res* 62(3): 495-504; 1979.

Arginine deprivation sensitized CHO cells to the clastogenic activity of the mutagenic agents UV light, N-methyl-N'-nitro-N-nitrosoguanidine (MNNG), mitomycin C and 4-nitroquinoline-1-oxide. Cells were allowed to undergo proliferative arrest by arginine deprivation, then were treated with mutagenic agent and refed with complete medium. The resulting mitotic cells displayed more chromosome aberrations than did mitotic cells in proliferating cell cultures treated similarly with mutagens. This effect was observed at each dose tested (representing a 300-fold range in concentration). Survival of arginine-deprived cells exposed to UV light was also markedly reduced in comparison to the response of proliferating cells. Sister-chromatid exchange levels induced by MNNG, in contrast, were similar in arginine-deprived and proliferating cells. (22 refs)

- 79-6225 Species Variation in BrdUrd-induced Sister-Chromatid Exchanges. (Eng) McFee, A. F. (Comparative Animal Res. Lab., Oak Ridge, TN 37830); Sherrill, M. N. *Mutat Res* 62(1): 131-138; 1979.

Species variation in 5-bromodeoxyuridine (BrdUrd)-induced sister-chromatid exchanges was studied. Peripheral blood lymphocytes from cattle, pigs, sheep, and humans were cultured in the presence of 0.5, 1, 2, 5, 10, or 20 $\mu\text{g/ml}$ of BrdUrd. Sister-chromatid exchanges were scored in 25 second-division metaphases from each donor at each level of the chemical. Dose-response curves for all four species increased steeply to 2 $\mu\text{g/ml}$; above this level, SCE numbers increased less rapidly but maintained a linear relationship to increasing BrdUrd concentrations. Comparisons of the straight-line portions of the dose-response curves showed that human cells were significantly more sensitive to increasing BrdUrd concentrations than cow or pig cells and different from sheep cells at the 10% confidence level. (19 refs)

- 79-6226 Effects of Caffeine on Chromosome Aberrations and Sister-Chromatid Exchanges Induced by Mitomycin C in BrdU-labeled Human Chromosomes. (Eng) Shiraishi, Y. (Lab. Cell Biology, Dept. Anatomy, Kochi Medical Sch., Nagoku-City, Kochi 781-51, Japan); Yamamoto, K.; Sandberg, A. A. *Mutat Res* 62(1): 139-149; 1979.

The 5-bromodeoxyuridine (BrdU) - Hoechst staining technique was used to analyze the effect of caffeine (CAF) on chromosome aberrations and sister-chromatid exchanges (SCE's) induced by mitomycin C (MC) in lymphocytes from normal individuals. CAF increased the frequency of SCE's in MC-treated chromosomes in all specimens. The combination of MC and CAF markedly increased all types of chromosome aberrations, but the most startling effect was the appearance of many cells with multiple aberra-

tions (shattered chromosomes). The BrdU-Hoechst technique showed that the shattered chromosomes did not appear in cells that had replicated only once, but they did occur in cells that replicated twice in the presence of MC and CAF. The large majority of chromatid breaks did not involve areas common to SCE's, and the SCE frequency significantly increased in spite of the existence of multiple breaks. This indicates that very few of the breaks are incomplete exchanges and that the mechanism for the formation of SCE's might be different from that of chromosome breaks. In another experiment, monofunctional MC had a small effect on SCE rates, although it induced shattered chromosomes in combination with CAF. Possible differences in the mechanisms leading to SCE's and chromosome breaks are discussed. (27 refs)

- 79-6227 Inhibition by Oncornavirus of a System of DNA Repair Induced by the Chemical Carcinogen 4-Nitroquinoline-1-oxide. (Rus) Andzhaparidze, O. G. (Res. Inst. Virus Preparations, Moscow, USSR); Zasukhina, G. D.; Vostrova, N. G.; Stepanova, L. G.; Avakova, A. N. *Dokl Akad Nauk SSSR* 247(6): 1498-1501; 1979.

An attempt was made to evaluate whether human cells infected with oncornavirus can repair the DNA breaks induced by the chemical carcinogen 4-nitroquinoline-1-oxide (4-NQO). Cultured diploid human cells (line T-9) infected with oncornavirus (strain LPV) were treated with 4-NQO (1×10^{-7} - 5×10^{-6} M) for 30 or 60 min; then cell lysates were centrifuged in sucrose gradient, and the number of breaks was determined from the mol wt of gradient fractions. It was found that noninfected and transformed cells were capable of repairing 4-NQO-induced DNA breaks (coefficient of repair, 90%-100%), while cells infected with LPV virus showed marked inhibition of DNA repair (coefficient of repair, 0%-52%). - 79-6228 Mutagenicity Evaluation of the Two Antimalarial Agents Chloroquine and Mefloquine, Using a Bacterial Fluctuation Test. (Eng) Schupbach, M. E. (Biological and Pharmaceutical Res. Dept., F. Hoffmann-La Roche and Co., Ltd., Basel, Switzerland). *Mutat Res* 68(1): 41-49; 1979.

Two antimalarial agents, chloroquine diphosphate (7-chloro-4-(4-diethylamino-1-methylbutylamino)-quinoline-diphosphate) and Mefloquine hydrochloride (2,8-bis-(trifluoromethyl-a-(2-piperidyl)-4-quinolinemethanol hydrochloride) were tested for mutagenicity in *Salmonella typhimurium* strains TA1535, TA1537, and TA1538 by a fluctuation test. Chloroquine reverted strain TA1537 without metabolic activation at concentrations of 100 and 250 $\mu\text{g/ml}$, probably by intercalation. No mutagenicity was found with mefloquine at concentrations of 0.5-2.4 $\mu\text{g/ml}$, with or without metabolic activation. Concentrations above 2.5 $\mu\text{g/ml}$ inactivated the bacteria and could not be tested. The high correlation between mutagenicity and carcinogenicity makes it likely that chloroquine is carcinogenic. Because of the mutagenic and probably carcinogenic risk of chloroquine and because of the increasing need for new antimalarial drugs, the existence of other antimalarial compounds, eg, mefloquine, which do not bind to DNA, should be stressed. (26 refs)

- 79-6229 Endocytosis and Chloroquine Accumulation During the Cell Cycle of Hepatoma Cells in Culture. (Eng) Quintart, J. (Laboratoire de Chimie Physiologique, Université de

CHEMICAL CARCINOGENESIS

Louvain, Louvain, Belgium); Leroy-Houyet, M. A.; Trouet, A.; Baudhuin, P. *J Cell Biol* 82(3): 644-653; 1979.

Endocytosis in hepatoma tissue culture (HTC) cells was studied by following the accumulation of horseradish peroxidase (HRP), radiolabeled dextran, and chloroquine. In asynchronously growing cells exposed for 1 hr to 5 mg/ml peroxidase, HRP uptake was linear for at least 3 hr. In synchronized cells, the accumulation was lowest at mitosis and increased during the first hours of the G1 phase. Between 16-20 hr after mitosis, accumulation decreased. A similar pattern was observed for the uptake of dextran (0.5 or 1 mg/ml). Dextran was largely recovered in soluble form upon homogenization, and its transfer to lysosomes was much slower than that of peroxidase. It is postulated that a significant portion of the dextran is adsorbed to the pericellular and phagosomal membranes, which results in the slow transfer into lysosomes. The variation in dextran uptake during the cell cycle probably reflects changes in both the adsorptive properties of the pericellular membrane and in the endocytic uptake rate. The kinetics of accumulation of chloroquine in synchronously growing HTC cells were also nonlinear. It was taken up more rapidly during G1 and S, while accumulation was lowest in mitotic cells. Since chloroquine uptake is an indirect way of measuring the pH and buffering capacity of lysosomes, the observations indicate that these properties vary in parallel with changes in endocytic properties during the cell cycle. It is concluded that actively dividing cells in culture are capable of regulating the processing of substances taken up from the surrounding medium, under the sole influence of intracellular events. No evidence for the intervention of lysosomes in mitosis was obtained. (41 refs)

79-6230 Adenine N⁶-Substituent of Agrocins 84 Determines its Bacteriocin-like Specificity. (Eng) Tate, M. E. (Waite Agricultural Res. Inst., Univ. Adelaide, Glen Osmond, S. Australia 5064); Murphy, P. J.; Roberts, W. P.; Kerr, A. *Nature* 280(5724): 697-699; 1979.

Structural determinants of the bacteriocin-like specificity of agrocins 84 (the active factor in the biological control of crown gall, a plant cancer induced by certain strains of *Agrobacterium*) were studied. For the pathogenic strain 57A, agrocins 84 was 360-fold more potent than its nucleotide fragment. However, the non-pathogenic strain 57 was inhibited by the nucleotide degradation fragment but not by agrocins 84 at a similar range of molarities. Thus, the nucleotide fragment without the N⁶-D-glucosylphosphoramidate substituent showed the nonspecific growth inhibition of a simple antibiotic, whereas only agrocins 84 with its unusual N⁶ substitution showed the strain specificity of a bacteriocin for the pathogenic strain 57A. For detectable antibiotic activity, a phosphoramidate linkage at the amphiphilic 2,3-dihydroxy-4-methylpentanamide appeared to be mandatory. The pathogenic in planta transconjugant strain 57A was originally obtained using the nonpathogenic strain 57 as the recipient and the pathogenic strain 27 as donor. Strain 57A differed from strain 57 solely by the presence of an electrophoretic band corresponding in mobility to the 1.5 x 10⁶ mol wt donor strain 27 tumor inducing plasmid. (14 refs)

79-6231 Cyclic Nucleotide Concentrations in Asbestos-induced Rat Peritoneal Mesothelioma. (Eng) Stevens, R. H. (Radiation Res. Lab., Dept. Radiology, Univ. Iowa, Iowa City, IA 52242); Will, L. A.; Cole, D. A.; Meek, E. S.; Frank, C. W.; Donham, K. J. *Environ Res* 19(2): 442-448; 1979.

The roles of cyclic AMP (cAMP) and cyclic guanosine monophosphate (cGMP) in the development and growth of asbestos-induced peritoneal mesotheliomas in the rat were determined. Peritoneal mesotheliomas were induced through the ip administration of Rhodesian chrysotile "A" to weanling male Holtzman rats. The intracellular concentrations of cAMP and cGMP were significantly less than the levels measured in comparable control tissues obtained from age-matched animals that had been similarly administered charcoal instead of the asbestos. The calculated molar ratio of cAMP to cGMP was identical in tumors and control tissue, implying that the two cyclic nucleotides were diminished by a constant factor in the tumor tissue. However, if tumorigenesis is related to the cAMP/cGMP balance within the cancer cell, then in these apparently noninvasive lesions such an equilibrium exists as is found in cells of normal mesentery. These results indicate that asbestos-induced mesotheliomas are similar to other cancerous tissues of the digestive tract in that they contain less of the adenosine cyclic nucleotide than the normal tissue. The findings suggest the possible loss of important cellular regulatory mechanisms in tumors induced by an important environmental carcinogen. (20 refs)

79-6232 Induction of Reproductive System Tumors in Mice by N⁶-(Methylnitroso)-adenosine and a Tumorigenic Effect of Its Combined Precursors. (Eng) Anderson, L. M. (Walker Lab., Memorial Sloan-Kettering Cancer Center, Rye, NY 10580); Giner-Sorolla, A.; Greenbaum, J. H.; Last-Barney, K.; Budinger, J. M. *Int J Cancer* 24(3): 319-322; 1979.

N⁶-(Methylnitroso)adenosine [m⁶(NO)Ado] was given in the drinking water (1 millimolar soln) of noninbred Swiss mice from 3 wk of age until death. This treatment resulted in the appearance of primary lung tumors in 16/20 females and 13/19 males; this was a significantly greater tumor incidence than the 19% occurring in both male (4/21) and female (3/16) control mice. At least one reproductive system tumor was found in 18/20 m⁶(NO)Ado-exposed females, including mammary tumors in 12 and uterine tumors in 5. The precursors of m⁶(NO)Ado, N⁶-methyladenosine (m⁶Ado) and nitrite, did not elevate tumor incidence when given alone; but when administered together they induced lung tumors in 11/19 male mice compared to 4/21 controls. Exposure of the mice to the nitrosated base N⁶-(methylnitroso)adenine [m⁶(NO)A] caused a significant increase in the number of lung tumors in male mice (11/19). Mammary tumors occurred in three females given m⁶(NO)A. The tumorigenic effect of m⁶Ado plus nitrite implies in vivo (probably intragastric) formation of a carcinogen, probably m⁶(NO)Ado. (13 refs)

79-6233 Esophageal Carcinoma in the Rat Induced with Methyl-alkyl-nitrosamines. (Eng) Stinson, S. F. (Tumor Pathology Branch, NCI, NIH, Bethesda, MD 20014). *Am J Pathol* 96(3): 871-874; 1979.

The previously reported induction of esophageal neoplasms by N-methyl-N-benzyl nitrosamine (MBZN): 2.5 mg/kg, sc, 1x/wk x 20) in F344 rats is described. All treated animals developed neoplasms as early as 18-20 wk after the first injection. Sixty-six percent of the lesions were papillomas, 17% pedunculated papillary carcinomas, and 17% sessile carcinomas. Histologically, all neoplasms showed squamous differentiation. Most carcinomas that invaded the esophageal wall were characterized by prominent intraluminal proliferation of well-differentiated squamous cells in

a papillary arrangement. Deep penetration of the wall by anaplastic chords of poorly differentiated cells was common. Although the carcinomas were invasive, no metastasis to distant sites was observed. No proliferative or neoplastic changes were induced in other organs by MBZN. Squamous cell carcinoma is the most frequently observed type of human esophageal cancer. The human neoplasms are usually well-differentiated and are deeply invasive. Growth patterns are also similar in this rat model and human esophageal cancer. Although the predominant papillary form of esophageal neoplasm in the rat is rare in man, a few cases have been reported. It is concluded that this model will be useful for the study of human esophageal carcinoma. (9 refs)

- 79-6234 Differential Expression of α -Fetoprotein and γ -Glutamyltranspeptidase in Chemical and Spontaneous Hepatocarcinogenesis. (Eng) Jalanko, H. (Div. Immunology, City of Hope Natl. Medical Center, Duarte, CA 91010); Ruoslahti, E. *Cancer Res* 39(9): 3495-3501; 1979.

The expression of two markers of fetal liver, α -fetoprotein (AFP) and γ -glutamyltranspeptidase (GGT), was studied during spontaneous and o-aminazotoluene (AT)-induced carcinogenesis in female C3H/A/BOM mice and male C3HeB/FeJ mice (AT given as 0.006% of the diet). Elevated serum AFP was first observed 3 wk after commencement of AT feeding in the female C3H/A/BOM mice. This increase subsided and was followed by a sustained increase at 5 mo. After 8 mo of carcinogen feeding and 2.5 mo on a normal diet, grossly visible liver tumors were observed in 25/28 (89%) mice. The liver in all 25 cases was covered by 10-50 small nodules, and large hepatomas were present in 12 animals. Some small oval cells and scattered adult-type hepatocytes contained AFP during the early stage of chemical carcinogenesis. During the later phase, AFP was detected in a few of the nodular areas, in solitary hepatocytes, and in groups of carcinoma cells. Spontaneous hepatomas in male C3HeB/FeJ mice also contained AFP. Fetal rat liver contained 100- to 1,000-fold more GGT than adult liver. During AT carcinogenesis, a significant increase in GGT was evident within 1 wk; this increase preceded that of AFP. No increase in GGT activity was found in the spontaneous benign or malignant liver lesions, however. The results indicate that the production of AFP and GGT is not turned on as a single 'genetic package', and that these two markers differ in their behavior during liver carcinogenesis. (31 refs)

- 79-6235 Mutagenic Activation of 2,4-Diaminoanisole and 2-Aminofluorene In Vitro by Liver and Kidney Fractions from Aromatic Hydrocarbon Responsive and Nonresponsive Mice. (Eng) Aune, T. (Dept. Environmental Toxicology, Natl. Inst. Public Health, Oslo 1, Norway); Dybing, E. *Biochem Pharmacol* 28(18): 2791-2797; 1979.

The mutagenicities of the two carcinogenic arylamines 2,4-diaminoanisole (2,4-DAA, 5-50 μ g) 2-aminofluorene (AF, 2-10 μ g) were compared using liver and kidney fractions from two aromatic hydrocarbon (3-methylcholanthrene, MC) responsive and two nonresponsive mouse strains. MC pretreatment (80 mg/kg ip) of mice caused an increase in 2,4-DAA mutagenicity with liver fractions from all four strains. Kidney fractions had very low basal 2,4-DAA mutagenic activity. MC treatment led to a 14- to 27-fold increase in 2,4-DAA mutagenicity in the responsive C57BL/6/BOM (B6) strain, but not in any of the other strains. AF mutagenicity was increased with liver fractions from all four mouse strains, to the greatest extent in the B6 mice. AF showed

high basal mutagenic activity with kidney fractions from all four strains, but MC treatment did not cause any increase in AF mutagenicity in any of the strains. Thus, there was a clear difference in the pattern of metabolic activation of the two arylamines by liver and kidney fractions in mice, both with respect to constitutive activities and the response to aromatic hydrocarbons. (18 refs)

- 79-6236 Changes in Polyamine Content During Hepatocarcinogenesis. (Eng) Nagarajan, B. (Cancer Inst., Madras-600 020, India); Sukumar, S. *Indian J Cancer* 15(4): 55-59; 1978.

Polyamine, polyamine biosynthesis enzyme, ornithine carbamyl transferase (OCT), arginase, and nucleic acid levels were studied in 3'-methyl-dimethylaminoazobenzene (3'-Me-DAB) carcinogenesis. Six-wk-old Wistar albino rats were fed a diet containing 3'-Me-DAB (600 mg/kg diet) for 90-100 days followed by 3-4 mo on stock diet. Animals were examined weekly for histological liver changes, and an attempt was made to correlate cell dedifferentiation with changes in the enzyme activities. Ornithine decarboxylase showed a gradual increase after the initiation of treatment and had almost doubled by the ninth wk. OCT and arginase activities gradually decreased after the start of treatment. As early as the first wk, OCT activity dropped to 50% of the normal liver level. The decrease in arginase activity was slower than that of OCT. There was a progressive increase in total liver DNA during the period of azo-dye feeding, but there was little change in the RNA level until the fourth wk, after which there was a slight decline. The DNA/RNA ratio of 0.22 rose to almost 1.0 by the 17th wk of DAB administration. The concentrations of putrescine, spermidine, and spermine all rose during DAB treatment. (10 refs)

- 79-6237 Detection by Antihapten Antibodies of Liver-bound Compounds Related to Azocarcinogens or Their Metabolites. (Eng) Carruthers, C. (Orchard Park Labs., Roswell Park Memorial Inst., New York State Dept. Health, Buffalo, NY); Baumler, A.; Lin, J. K. *Oncology* 36(5): 211-215; 1979.

The localization of known azocarcinogens and metabolites bound to components of liver cells of male Fischer rats (CDF inbred strain) that received azo compounds by stomach tube was determined using antibodies raised against a number of these compounds in the indirect fluorescent antibody procedure. The rats received 3'-methyl-*p*-dimethylaminoazobenzene (3'-Me-DAB), *N*-methyl-*p*-aminoazobenzene (MAB), *p*'-amino-*p*-aminoazobenzene (*p*'-amino-*p*-AAB), or *p*'-amino-*N*-monomethyl-*p*-aminoazobenzene (*p*'-amino-*p*-MAB) at 20 mg/100 g body wt and sacrificed 17 or 41 hr (3'-Me-DAB-treated rats) later. Antisera raised against *p*-azo-*N*-acetyl-*N*-methylaniline (*p*-azo-AMA), azoaniline, *p*-azo-*N*-monomethylaniline, and *p*-azoazobenzene (*p*-AB) reacted in agar producing precipitin lines of identity with the cytosols prepared from the livers of rats fed each of the azo compounds. In the fluorescent antibody procedure, *p*'-azo-*N*-monomethyl-*p*-aminoazobenzene and *p*'-azo-*p*-aminoazobenzene antisera reacted strongly with liver cells of rats red 3'-Me-DAB or MAB, and *p*-AB antisera reacted strongly with liver cells of rats fed *p*'-amino-*p*-MAB, MAM, or *p*'-amino-*p*-AAB. These results suggest that both minor and major metabolites of azocarcinogens have common antigenic determinants and indicate that these metabolites are bound to liver cell components. (11 refs)

79-6238 Rubber Solvent: A Clastogenic Agent that Fails to Induce Sister-Chromatid Exchanges. (Eng) Altenburg, L. C. (Medical Genetics Center, Univ. Texas Health Science Center at Houston, Houston, TX 77025); Ray, J. H.; Smart, C. E.; Moore, F. B. *Mutat Res* 67(4): 331-341; 1979.

Rubber solvent (a mixture of paraffins, monocycloparaffins, monoolefins, benzene, and alkyl benzene) was tested for its ability to induce chromosome aberrations and sister chromatid exchanges (SCEs) in whole blood cultures from a normal human donor. The solvent proved to be a clastogenic agent for human whole blood, the highest concentration tested (0.0750%) producing at least a threefold increase in all types of chromosome aberrations. As the solvent concentration increased from 0%-0.750%, the number of cells showing one or more aberrations increased to a max of slightly over 50% of the cells. Chromosomal aberrations included gaps, chromatid breaks, and chromosome pulverization. There were no increases in SCE frequency at any of the solvent concentrations tested. The absence of increased SCE frequency in these cells suggests that DNA replication is not required for the induction of chromosomal aberrations by the clastogenic agent(s) in rubber solvent. (40 refs)

79-6239 Induction of Dominant Lethal Mutations in Male Mice by Fosfestrol. (Eng) Ehling, U. H. (Abteilung für Genetik der Gesellschaft für Strahlen und Umweltforschung, Ingolstädter Landstrasse 1, D-8042 Neuherberg, W. Germany). *Arch Toxicol* 42(3): 171-177; 1979.

The ability of fosfestrol, a diethylstilbestrol derivative, to induce mutations in male mice was tested and confirmed in a dominant lethal assay. With up to 300 mg/kg of fosfestrol, the induction of mutations occurred exclusively in spermatozoa. A dose of 600 mg/kg fosfestrol induced dominant lethal mutations up to 10 days posttreatment. In all dose groups, the majority of the induced dominant lethal mutations were expressed as losses after implantation. (15 refs)

79-6240 Carcinomas of the Liver in Female Mice Fed Toluene-2,4-diamine. (Eng) Reuber, M. D. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, P. O. Box B, Frederick, MD 21701). *Gann* 70(4): 453-457; 1979.

The hepatocarcinogenicity of toluene-2,4-diamine was tested in B6C3F1 mice fed 100 or 200 ppm in the diet for 100 wk. Females fed both doses of the aromatic amine developed significant numbers of liver carcinomas (39% of those fed 200 ppm, $p = 0.00093$; 30% of those fed 100 ppm, $p = 0.00010$), and these included both well differentiated and poorly differentiated tumors. Treated mice also developed hyperplastic hepatic nodules, but cirrhosis was not observed. The incidence of hepatic neoplasms (carcinomas + hyperplastic nodules) was significant ($p \leq 0.00001$) in female mice. Hyperplastic nodules, carcinomas, and liver cirrhosis have been previously described in rats fed toluene-2,4-diamine. (16 refs)

79-6241 Chemical Studies on Tobacco Smoke LXIV. On the Analysis of Aromatic Amines in Cigarette Smoke. (Eng) Patrianakos, C. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595); Hoffmann, D. *J Anal Toxicol* 3(4): 150-154; 1979.

An analytical method for aromatic amine profiles in cigarette smoke was developed, and a comparative study of aromatic amines in various tobacco products was carried out. Amines from smoke are trapped in dilute hydrochloric acid and are enriched together with the basic portion, derivatized to pentafluoropropionamides and determined by gas chromatography with a ^{63}Ni -electron capture detector (detection limit 50 pg aniline/cigarette). The mainstream smoke of one US 85-mm cigarette without filter tip contained 102 ng of aniline, 61 ng of 2-toluidine, 3-toluidine, and 4-toluidine, 55.8 ng of ethylaniline and dimethylaniline, 4.3 ng of 1-naphthylamine, 6.9 ng of 2-aminobiphenyl, 3-aminobiphenyl, and 4-aminobiphenyl, and 5.8 ng of 2-methyl-1-naphthylamine. Sidestream smoke contained levels of aromatic amines 20 to 68 times higher than those in the mainstream smoke. The results from smoke analyses of experimental cigarettes support the concept that the nitrate and protein content of tobacco are determining factors for the smoke yields of aromatic amines. (21 refs)

79-6242 Collaborative Studies on the Salmonella/Microsome Mutagenicity Assay. (Eng) Dunkel, V. C. (NCI, NIH, Bethesda, MD 20014). *J Assoc Off Anal Chem* 62(4): 874-882; 1979.

A collaborative study was undertaken to determine the reproducibility of results obtained with the Salmonella/microsome mutagenicity assay. Three laboratories tested 61 carcinogens and noncarcinogens with and without metabolic activation using *S. typhimurium* strains TA1535, TA1537, TA98, and TA100. The metabolic activation systems were derived from the livers of uninduced and Aroclor 1254-induced Fischer rats, B6C3F₁ mice, and Syrian hamsters. Eight of 23 chemicals were negative and 13 were positive when tested by all three laboratories. Two chemicals, 2-methyl-4-dimethylaminoazobenzene and parosanol, were positive according to two laboratories and negative according to the third. There was complete agreement among laboratories with regard to overall negative responses. Except for the two compounds mentioned, all laboratories obtained positive responses with activation-dependent chemicals in at least one activation system. Species variation was observed in the ability of the S-9 mix to metabolize chemicals to active mutagens; in each case, there was increased activity with the hamster preparations. In general, better responses were obtained with enzyme preparations from induced animals than with those prepared from uninduced animals. (3 refs)

79-6243 Genetic Toxicity of Procarbazine in Bacteria and Yeast. (Eng) Bronzetti, G. (Lab. Mutagenesi e Differenziamento, Via Cisanello 147B, Pisa, Italy); Zeiger, E.; Malling, H. V. *Mutat Res* 68(1): 51-58; 1979.

Procarbazine [*N*-isopropyl- α -(2-methylhydrazino) - *p*-toluamide hydrochloride], used to treat Hodgkin's disease, was tested in vitro with and without the S10 fraction from mice liver (microsomal assay) using *Saccharomyces cerevisiae* strain D₁, *Salmonella typhimurium* (strains TA98, TA100, TA1535), and in vivo in Swiss albino mice (host-mediated assay) using D₁. Procarbazine, without S10 fraction, was highly toxic and induced mitotic crossover, gene conversion, and reverse mutation in D₁ at all doses tested in vitro [17, 34, or 68 mg/ml]. It had a toxic effect on all the *Salmonella* strains at concentrations ranging from 10-100 mg/ml, but did not induce reverse mutations at the histidine loci. Procarbazine with S10 fraction was less toxic and did not induce genetic effects in

yeast or *Salmonella*. In the host-mediated assay, no genetic effects were seen. (34 refs)

- 79-6244 Oxidative Metabolism of *N*-Isopropyl- α -(2-methylhydrazino)-*p*-toluamide Hydrochloride (Procarbazine) by Rat Liver Microsomes. (Eng) Dunn, D. L. (Dept. Biochemistry, Univ. Texas Health Science Center at Dallas, Dallas, TX 75235); Lubet, R. A.; Prough, R. A. *Cancer Res* 39(11): 4555-4563; 1979.

The oxidative metabolism of procarbazine (*N*-isopropyl- α -(2-methylhydrazino)-*p*-toluamide hydrochloride) by rat liver microsomes was studied utilizing three different biochemical assays. Using high-pressure liquid chromatography, it was observed that the major stable microsomal metabolite produced was the azo derivative, *N*-isopropyl- α -(2-methylazo)-*p*-toluamide, which was able to undergo a rapid chemical conversion to the aldehyde *p*-formyl-*N*-isopropylbenzamide and methylhydrazine upon the addition of acid. The rate of metabolism could most conveniently be determined spectrophotometrically by reacting the resultant methylhydrazine with *p*-dimethylaminobenzaldehyde. Alternately, *p*-formyl-*N*-isopropylbenzamide could be extracted directly from the acid-treated mixture with an organic solvent, and its concentration could be determined spectrophotometrically. Rates of metabolism using all three assays ranged from 13.4-14.1 nanomoles/min/mg of microsomal protein. Inhibitor and induction studies indicated that the cytochrome P-450-dependent monooxygenase system is responsible for this oxidation reaction. Several possible mechanisms were considered: either a direct dehydrogenation of a preliminary *N*-oxidation by cytochrome P-450 followed by a rapid dehydration step. The azo derivative of procarbazine was further oxidized to two isomeric azoxy derivatives, *N*-isopropyl- α -(2-methyl-NNO-azoxy)-*p*-toluamide and *N*-isopropyl- α -(2-methyl-ONN-azoxy)-*p*-toluamide, at a metabolic rate which was 10-15% as great as the rate of procarbazine oxidation. In addition, the affinity of the azo derivative for the monooxygenase was high relative to that of the parent hydrazine. The reaction was inhibited by cytochrome P-450 inhibitors and was sensitive to the *in vitro* addition of several thionosulfur-containing compounds. The azoxy compounds were also metabolized by microsomal fractions from liver and yielded *p*-formyl-*N*-isopropylbenzamide as a product. This complex *in vitro* metabolic scheme is analogous to the *in vivo* metabolism of 1,2-dimethylhydrazine and suggests that procarbazine may be metabolically activated to yield alkylating agents capable of expressing carcinogenic and/or toxic effects by a mechanism common to at least these two *N,N'*-disubstituted hydrazines. (43 refs)

- 79-6245 Accelerating Effect of Ascorbic Acid on *N*-Nitrosamine Formation and Nitrosation by Oxyhyponitrite. (Eng) Chang, S. K. (Johnson and Johnson Co., New Brunswick, NJ); Harrington, G. W.; Rothstein, M.; Shergalis, W. A.; Swern, D.; Vohra, S. K. *Cancer Res* 39(10): 3871-3874; 1979.

The reaction of nitrite ion with ascorbic acid and its effect on the rate of nitrosation of secondary amines were investigated using differential pulse polarography in aqueous acidic solution. Ascorbic acid showed nonuniform behavior: it accelerated the nitrosation of *N*-methylaniline between pH 1.00 and 1.95, allowed the nitrosation of diphenylamine and iminodiazetonitrile, and inhibited the nitrosation of secondary amines such as

dimethylamine, diethylamine, proline, hydroxyproline, *N*-methylaminoacetonitrile, *N*-methylaminopropionitrile, and sarcosine. The three amines that were nitrosated were relatively weak bases, whereas those that were not were relatively strong. The nitrosating agent generated by the reaction between ascorbic acid and nitrite ion appeared to be oxyhyponitrite ion. The addition of ascorbic acid to a commercial product containing a variety of unknown amines might slow down the formation of some nitrosamines but accelerate the formation of others, which might generate more potent carcinogens by transnitrosation. (32 refs)

- 79-6246 The *N*-Hydroxy Metabolites of *N*-Methyl-4-aminoazobenzene and Related Dyes as Proximate Carcinogens in the Rat and Mouse. (Eng) Miller, E. C. (McArdle Lab. Cancer Res., Univ. Wisconsin Center Health Sciences, Madison, WI 53706); Kadlubar, F. F.; Miller, J. A.; Pitot, H. C.; Drinkwater, N. R. *Cancer Res* 39(9): 3411-3418; 1979.

The carcinogenicities for rats and mice of the dye *N*-methyl-4-aminoazobenzene (MAB) and its hepatic microsomal metabolite *N*-hydroxy-*N*-methyl-4-aminoazobenzene (*N*-hydroxy-MAB) were compared under several conditions. The related dyes *N*-ethyl-4-aminoazobenzene (EAB), 4-aminoazobenzene (AB), and their *N*-hydroxy derivatives were also included in some of the assays. About 25% of the rats given MAB or *N*-hydroxy-MAB (3-5 millimoles/kg) by stomach tube over a 5-wk period developed hepatic tumors by 18-22 mo. Similarly treated rats subsequently given phenobarbital in the drinking water until the termination of the experiment developed about twice as many hepatic tumors. *Pro* administration of *N*-hydroxy-MAB, but not MAB, also induced multiple papillomas and extensive carcinomas of the forestomach in approx 50% of the rats. Only low incidences of hepatocellular carcinomas occurred in partially hepatectomized rats given a single ip injection of 180 micromoles of MAB or *N*-hydroxy-MAB with or without subsequent administration of phenobarbital. Although repeated sc doses of *N*-benzoyloxy-*N*-methyl-4-aminoazobenzene induced sarcomas at the injection site in 90% of the rats, only 3/20 rats developed sarcomas at the site of sc injections of *N*-hydroxy-MAB. EAB, AB, and their *N*-hydroxy derivatives did not induce significant numbers of tumors in any of the above assay systems. Administration to preweanling male mice of MAB, *N*-hydroxy-MAB, *N*-hydroxy-EAB, and *N*-hydroxy-AB resulted in high incidences and high multiplicities of hepatic tumors (av of 5-7 tumors/mouse) within 1 yr. EAB and AB also induced hepatic tumors under the same conditions, but they were less active. The data support the conclusion that the *N*-hydroxy metabolites of these aminoazo dyes are proximate carcinogens. (46 refs)

- 79-6247 Binding of the Chemical Carcinogen, *p*-Dimethylaminoazobenzene, by Human Plasma Low Density Lipoproteins. (Eng) Chen, T. C. (Dept. Biochemistry, Methodist Hosp., Baylor Coll. Medicine, Houston, TX 77030); Bradley, W. A.; Gotto, A. M.; Morrisett, J. D. *FEBS Lett* 104(2): 236-240; 1979.

p-Dimethylaminoazobenzene (phenyl-¹⁴C; ¹⁴C-DAB) was incubated with 1 ml of whole blood from normal male and female donors, plasma lipoprotein soln, or albumin soln for 6 hr. In experiments using whole blood, 15% of the radioactivity was distributed into cellular components, while the remainder was bound to the lipoproteins and lipid-free plasma proteins. When the three principal classes of lipoproteins [low density lipoproteins (LDL), high density lipoproteins (HDL), and very low density

lipoproteins (VLDL)] were separated by agarose gel filtration chromatography, 77% of the incorporated ^{14}C -DAB was associated with LDL, 10% with VLDL, and 13% with HDL. Incubation of ^{14}C -DAB (at a subsaturating level) with LDL and albumin present at a normal physiological ratio resulted in the distribution of 88% of the radioactivity into the LDL and 12% into the albumin fraction. This study does not establish the actual binding site(s) for the DAB but suggests that it may be bound at the hydrophobic core of the lipoproteins. Specific receptor sites for LDL exist in a variety of normal cells. If LDL is the major transport vehicle for water-insoluble carcinogens in vivo, then transfer of the carcinogens from LDL to these normal cells might cause neoplastic transformation if the accessible cells possess the necessary enzyme systems for carcinogenic metabolic activation. (25 refs)

- 79-6248 Recessive Lethals Induced by Styrene and Styrene Oxide in *Drosophila melanogaster*. (Eng) Donner, M. (Dept. Industrial Hygiene and Toxicology, Inst. Occupational Health, Helsinki, Finland); Sorsa, M.; Vainio, H. *Mutat Res* 67(4): 373-376; 1979.

The induction of recessive lethal mutations in phenobarbitone (PB)- or trichloropropane (TCP)-pretreated *Drosophila melanogaster* by styrene (200 ppm) and styrene oxide (SO: 200 ppm) was studied. The compounds were administered by feeding for 24 hr or inhalation for 6 hr/day over 4 consecutive days. In the feeding experiments, styrene was slightly more toxic than SO (LC_{50} approx 500 and 700 ppm, respectively). Neither PB nor TCP alone was mutagenic, but both increased the production of recessive lethals by styrene or SO by approx twofold. Styrene or SO alone significantly increased the number of recessive lethals over control rates. The increased yield of recessive lethals after combined treatment with PB plus styrene can be explained on the basis of an enhancement of the conversion of styrene to epoxide derivative(s). It is possible that further oxidation of styrene-7,8-oxide might take place at the 3,4-position of the aromatic ring, and this metabolic pathway could be stimulated by PB treatment in *Drosophila*. This mechanism could explain the enhanced mutagenicity of SO after PB treatment. (12 refs)

- 79-6249 Induction of Enzyme Activity in Cell Culture: A Rapid Screen for Detection of Planar Polychlorinated Organic Compounds. (Eng) Bradlaw, J. A. (Div. Toxicology, Food and Drug Admin., Washington, DC 20204); Casterline, J. L. *J Assoc Off Anal Chem* 62(4): 904-916; 1979.

The detection of planar polychlorinated organic compounds by the cell culture-enzyme induction bioassay is described. Aryl hydrocarbon hydroxylase (AHH) activity was measured by the conversion of benzo(a)pyrene (BP) to 3-hydroxy-BP in homogenized cell extracts from control and treated cultures. Substances screened by this method included polyhalogenated analogs of dibenzo-p-dioxin (24 compounds), dibenzofuran (11), biphenyl (7), and extracts from several food sources. The response of the most reactive compound, 2,3,7,8-tetrachlorodibenzo-p-dioxin, was used to prepare a standard curve, and the AHH activity induced by mole doses of each test substance was reported as an ED_{50} response (the estimated dose needed to produce 50% of max enzyme induction). A potent ED_{50} response in cell culture appeared to correlate well with known toxic responses in other mammalian and avian systems for certain test substances. This correlation suggests that the cell culture-enzyme induction method is a

useful model for screening food extracts that are suspected of being contaminated with polychlorinated planar substances. (31 refs)

- 79-6250 An Estimate of the Maximum In Vivo Covalent Binding of 2,3,7,8-Tetrachlorodibenzo-p-dioxin to Rat Liver Protein, Ribosomal RNA, and DNA. (Eng) Poland, A. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Glover, E. *Cancer Res* 39(9): 3341-3344; 1979.

In light of the recently discovered potent carcinogenicity of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) in female rats, the in vivo covalent binding of ^3H TCDD to rat liver macromolecules was reexamined. Immature Sprague-Dawley rats, receiving ^3H TCDD (0.87 mCi/kg; specific activity, 39 Ci/millimole) concentrated 18%-64% of the total administered dose in their livers, but virtually all of this radioactivity (>99.9%) was extractable. The max unextractable radioactivity was: protein, 60 picomoles (pmol) TCDD/mole (mol) of amino acid residue; ribosomal RNA, 12 pmol TCDD/mol of nucleotide residue; and DNA, 6 pmol TCDD/mol of nucleotide residue. If one assumes that this small residual amount of radioactivity represents covalent binding, this binding is four to six orders of magnitude lower than that of most chemical carcinogens, and the binding to DNA is equivalent to one molecule of TCDD per DNA, equivalent to 35 cells. The results suggest that it is unlikely that TCDD-induced oncogenesis is through a mechanism of covalent binding to DNA and somatic mutation. (29 refs)

- 79-6251 Carcinogenic Properties of Dicarboxydine (γ,γ' -3,3'-benzidine dioxydibutyric Acid). (Eng) Pliss, G. B. (Lab. Chemical Carcinogenic Agents, Petrov Res. Inst. Oncology, 68 Leningradskaya St., Pesochny-2, Leningrad 188646, USSR); Volfson, N. I. *Arch Geschwulstforsch* 49(3): 229-239; 1979.

The carcinogenicity of dicarboxydine (DCD) for male and female rats (35 or 45 mg/wk DCD, sc for 24 mo or 20 mg DCD po 5 days/wk for 24 mo) and male and female CC₅₇Br mice (3 or 4 mg/wk, sc or 3 mg/day po 5 days/wk) was studied. The percentages of tumors developing in the treated rats was 13.6% in the low-dose sc group, 26.2% in the high-dose sc group, and 28.6% in the po group, as compared with 19% in a control group. The latent periods of tumor development did not differ significantly between DCD and control groups. Four DCD-treated rats developed sarcomas at the injection site and others developed tumors of the bladder, prostate, uterine body, and other sites; tumors of these sites were not found in the control rats. DCD showed no significant tumorigenic activity in the mice. The results suggest that DCD possesses low carcinogenic activity. (9 refs)

- 79-6252 Genetic Effects of Impure and Pure Saccharin in Yeast. (Eng) Moore, C. W. (Dept. Radiation Biology and Biophysics, Univ. Rochester, Rochester, NY 14642); Schmick, A. *Science* 205(4410): 1007-1010; 1979.

The effects of pure and impure saccharin on mitotic and intragenic recombination and reverse mutation in *Saccharomyces cerevisiae* were studied, and the extents to which these genetic events are affected by impure saccharin produced by two different processes were compared. The diploid strain CM-1293 of *S. cerevisiae* was

incubated in medium containing 0, 2, or 20 mg of saccharin A (impure Maumee process saccharin), B (impure Remsen-Fahlberg process), or C (purified from the same B batch). Dose-dependent increases were observed in the frequencies of abnormal cells. The frequency of aberrant types was saccharin A > saccharin B > saccharin C. Such aberrant cell types were not observed in cultures grown in medium without saccharin. Intergenic exchanges between homologous chromosomes were 11-12 times more frequent in cells grown in the presence of the lowest dose of impure saccharins than in cells grown without saccharin. Half as many exchanges occurred among cells grown with the low dose of saccharin C. At all three concentrations, cells grown in the presence of saccharin B showed higher frequencies of mitotic crossing over or gene conversion than cells grown in saccharin C. Saccharin A usually caused larger increases in both recombination and mutation than saccharins B and C, indicating the greater potential mutagenicity of saccharin A. It is concluded that the impurities in saccharin caused some or all of the observed genetic effects. However, the impurities would have to be potent to account for all the effects of saccharin and, therefore, saccharin per se or its metabolites might cause the effects. (19 refs)

- 79-6253 Saccharin Metabolism and Tumorigenicity. (Eng) Sweatman, T. W. (Clinical Pharmacology Group, Univ. Southampton, Medical and Biological Sciences Bldg., Southampton SO9 3TU, England); Renwick, A. G. *Science* 205(4410): 1019-1020; 1979.

Adult male Charles River CD1 rats that had been exposed to saccharin in utero and maintained on a 5% saccharin diet were given free access to a diet containing 5% [³H]saccharin for 24 hr and then returned to the unlabeled diet (pulsed-dose experiment). In another experiment, normal rats received a single dose of [³H]saccharin (60 µg/kg) by intubation or 3-methylcholanthrene (MCA: 20 mg/kg, po) 3 and 2 days before a single dose of [³H]saccharin (400 µg/kg, po). The ³H label was eliminated, largely in the urine, within 48 hr. In the pulsed-dose experiment, fecal excretion was 14%, while in the two other experiments, fecal excretion was 2.5%-3% in rats given the 60 µg/kg dose and 6.5%-8% in rats treated with MCA and 400 µg/kg saccharin. Urine samples obtained 0-24 hr after labeled saccharin administration in the pulsed-dose experiment contained 98.5% saccharin and <0.05% 2-sulfamoylbenzoic acid. Similar results were obtained in the untreated rats given 60 µg/kg saccharin. These results demonstrate that significant metabolism is not induced by long-term saccharin administration during the neonatal and weaning stages of two-generation studies. The possibility that the carcinogenic effects of saccharin are due to the unmetabolized parent compound, to a promoting effect, or to changes in physiological function should be investigated. (11 refs)

- 79-6254 Genetic Effects of Hydralazine. (Eng) Shaw, C. R. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., Houston, TX 77030); Butler, M. A.; Thenot, J. P.; Haegle, K. D.; Matney, T. S. *Mutat Res* 68(1): 79-84; 1979.

Hydralazine and its acetone condensation product were found to induce base-pair substitution mutations in the Salmonella/microsomal activation test system and to display genetic toxicity in the PolA⁺/A⁻ test system. A dose-response relationship was noted for mutagenicity of both compounds tested at doses up to 1,000 µg/plate. Incubation with a rat liver microsomal fraction did not

affect the genetic toxicity of either compound. Other derivatives of hydralazine, including the major metabolite 3-hydroxy-methyl-5-triazolo-[3,4a]phthalazine (MTP), did not yield any evidence of genetic toxicity, nor were they metabolically convertible to a toxic product. Therefore, individuals who convert hydralazine to MTP slowly, ("slow acetylators") would be expected to be at risk. (14 refs)

- 79-6255 Acute Leukemia After Azathioprine Therapy of Chronic Aggressive Hepatitis. (Ger) Krieger, G. (I. Medizinische Klinik, Städtisches Klinikum, Maltkestrasse 14, 7500 Karlsruhe 1, W. Germany); Keller, P.; Schirmeister, J. *Therapiewoche* (36): 5554-5555, 5558; 1979.

The case report of a 26-yr-old man who developed acute leukemia after receiving azathioprine (AZP: av dose, 150 mg/day) for 6 yr as treatment for chronic aggressive hepatitis is presented together with a literature review. Fluocortolone (Ultralan) was given briefly at 100 mg/day in 1969 and at 200 mg/day (shock therapy) in 1972. AZP was discontinued during fluocortolone therapy. The patient presented with leg pain, night sweats, and inguinal swelling, and rapidly developed an acute transverse-lesion syndrome. After brief improvement during chemotherapy, he died of heart failure, which was considered to be a result of leukemia. Autopsy showed massive infiltration of the lymphatic organs, liver, bone marrow and meninges with paramyeloblasts. Evidence of chronic aggressive hepatitis and the development of fibrosis was seen. Australia antigen was present in the serum at the time of the first diagnosis of hepatitis. Two reports of myeloid leukemia in patients treated with azathioprine were found in the literature, although neither patient had received alkylating agents. In other studies of 7,100 patients who received AZP for nonmalignant disease, no increased tumor incidence was observed. No increased tumor incidence was seen in 125 patients followed for 4 yr after treatment with azathioprine (100 mg/day) for an av of 2 yr. (29 refs)

- 79-6256 Activity of Citrinin Metabolized by Rat and Human Microsome Fractions in Clastogenicity and SCE Assays on Chinese Hamster V79-E Cells. (Eng) Thust, R. (Res. Group Preventive Oncology, Inst. Pathology Medical Acad. Erfurt, Nordhauser Strasse 74, DDR-50 Erfurt, E. Germany); Kneist, S. *Mutat Res* 67(4): 321-330; 1979.

The ability of the mycotoxin citrinin to induce chromosome aberrations and sister chromatid exchanges (SCE's) in Chinese hamster V79-E cells was investigated. In a clastogenicity assay, citrinin was a potent inducer of chromosome aberrations in the V79-E cells when metabolized by rat and human liver microsomes. Both types of microsomes, standardized with respect to protein content, activated citrinin at equal levels. At 5×10^{-4} M citrinin induced a high frequency of complex translocations as well as defects in chromosomal coiling. Higher concentrations were cytotoxic, lower ones almost inactive. After metabolization of the mycotoxin by rat kidney microsomes or an S9 mix fraction containing rat liver and kidney microsomes, toxic effects predominated and chromosome aberrations were diminished. Clastogenic citrinin concentrations did not increase the SCE frequency. Although the mode of action of this mycotoxin on chromosome structure remains obscure, several possible explanations are offered. (22 refs)

- 79-6257 Inhibitory Effects of Carcinogenic Mycotoxins on Deoxyribonucleic Acid-Dependent Ribonucleic Acid Polymerase and Ribonuclease H. (Eng) Tashiro, F. (Dept. Tox-

icology and Microbial Chemistry, Tokyo Univ. Science, Ichigaya, Shinjuku-ku, Tokyo 162, Japan); Hirai, K.; Ueno, Y. *Appl Environ Microbiol* 38(2): 191-196; 1979.

Fourteen mycotoxins were tested for in vitro inhibitory effects on RNA polymerase of rat liver and *Escherichia coli* and nuclear ribonuclease H of rat liver and *Tetrahymena pyriformis*. Both enzymes were strongly inhibited by (-)-luteoskyrin, (+)-rugulosin, patulin, and PR toxin. (+)-Rugulosin behaved like actinomycin D, which binds with DNA and inhibits RNA synthesis. Luteoskyrin selectively inhibited RNA synthesis by isolated rat liver nuclei and by RNA polymerases of rat liver, but not by RNA polymerases of *E. coli*. PR toxin inhibited RNA synthesis by both animal and bacterial RNA polymerases. The initiation, as well as the elongation reaction, of RNA polymerase I of rat liver was impaired by PR toxin, but with RNA polymerase II, PR toxin affected preferentially the initiation reaction. Rat liver ribonuclease H was inhibited by (-)-luteoskyrin, (+)-rugulosin, patulin, penicillic acid, and PR toxin. *O*-acetylsterigmatocystin and chlorocephalid did not inhibit in vitro RNA synthesis. Recovery from patulin-induced ribonuclease H inhibition in the presence of DDT, taken together with the results of previous experiments, supports the authors' proposal that patulin, penicillic acid, and PR toxin act as sulfhydryl group blockers with both ribonuclease H and RNA polymerase. (32 refs)

79-6258 Black Pepper [*Piper nigrum*]: Evidence of Carcinogenicity. (Eng) Concon, J. M. (Dept. Nutrition & Food Science, Univ. Kentucky, Lexington, KY 40506); Newburg, D. S.; Swerczek, T. W. *Nutr Cancer* 1(3): 22-26; 1979.

An extract of black pepper was applied cutaneously to albino Swiss mice of both sexes; each animal received a total of 28 mg over a 3-mo period. All pepper-treated mice surviving after 17 mo developed tumors, particularly in the lung, liver, and skin (distant from the area of application). The incidence of malignant tumors and of multiple tumors was significantly greater in the pepper-treated mice than in the vehicle-treated controls. (38 refs)

79-6259 Carcinomas and Other Lesions of the Liver in Mice Ingesting Organochlorine Pesticides. (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center, Frederick, MD 21701). *Toxicol Annu* 3: 231-256; 1979.

The induction and histopathology of carcinomas of the liver and other lesions in mice of various strains fed organochlorine pesticides were studied. A high incidence of well-, moderately well-, and poorly differentiated hepatocellular and cholangiocellular carcinomas was observed in mice given dieldrin, aldrin, heptachlor, heptachlor epoxide, kepone, lindane, chloroform, chlordane, or carbon tetrachloride. Increased incidences were also seen after the ingestion of chlorobenzilate, mirex, DDT, methoxychlor, or endrin. Hemangioendothelial sarcomas, leiomyosarcomas, and reticulum cell sarcomas were rarely seen in the livers of the pesticide-treated mice. Hyperplastic nodules were frequently observed in the livers of mice with and without liver tumors. There were occasional metastases to the lungs, the metastatic carcinomas being predominantly hepatocellular. Focal necrosis was occasionally seen in the treated mice, particularly those given heptachlor or heptachlor epoxide. Severe cirrhosis was observed in most animals given large doses of chloroform or carbon tetrachloride. (78 refs)

79-6260 Evaluation of Benzidine by the Micronucleus Test. (Eng) Cihak, R. (Res. Inst. Organic Syntheses, Pardubice-Rybitvi, Rosice, 533 51, Czechoslovakia). *Mutat Res* 67(4): 383-384; 1979.

Benzidine (100-300 mg/kg) and its derivative, 3,3'-dimethylbenzidine (DMB, 50-200 mg/kg) were tested for their mutagenicity using the micronucleus test in male Wistar rats. The compounds were administered by stomach tube 30 min and 6 hr before preparation of bone marrow smears. Both compounds significantly increased the frequency of micronucleated polychromatic RBC at all doses tested, but a dose-response relationship was observed only for DMB. The efficiency of the micronucleus test for the detection of carcinogens appears to be low, even when an appropriate experimental protocol is followed. (5 refs)

79-6261 Non-Mutagenicity of the Hair Dye, Henna, in the Ames Test. (Eng) Stamberg, J. (Dept. Microbiology, Faculty Life Sciences, Tel Aviv Univ., Ramat Aviv, Israel); Werczberger, R.; Koltin, Y. *Mutat Res* 62(2): 383-387; 1979.

The mutagenicities of henna and lawsone (2-hydroxy-1,4-naphthoquinone, the active coloring and medicinal ingredient in henna) for five histidine-requiring *Salmonella typhimurium* strains and the human epithelial AV3 cell line were studied. Henna at 0.2-1,000.0 µg/plate was not mutagenic for *S. typhimurium* strains TA1538, TA1537, TA1535, TA100, or TA98 (with and without metabolic activation with S9 mammalian-microsome fraction); it was mutagenic only for strain TA98 at concentrations ≥500 µg/plate and in the absence of S9 mix; in this case, there was a four- to sevenfold increase in reversion. Henna was toxic for *Salmonella* strains and *Ustilago maydis*, but there was no clear dose-response to henna or lawsone in either organism. Henna was toxic for human AV3 cells at doses >2 mg/ml. Five of six female C3H or C57BL mice given im injections of henna (5.0 mg/mouse) died within 11 days. ICR and BALB/c mice survived im injections of 5.0 or 10.0 mg/mouse. Topical application of henna (50 mg/mouse in three serial applications) in ICR and BALB/c mice produced neither death nor external malignancies after 9 mo of observation. (13 refs)

79-6262 Carcinogenicity and Nephrotoxicity of 2-Amino-, 1-Amino-2-methyl-, and 2-Methyl-1-nitro-anthraquinone. (Eng) Murthy, A. S. (EG&G Mason Res. Inst., Worcester, MA 01608); Russfield, A. B.; Hagopian, M.; Monson, R.; Snell, J.; Weisburger, E. K. *Toxicol Lett* 4(2): 71-78; 1979.

The carcinogenicity and nephrotoxicity of three cyclic dye intermediates, 2-aminoanthraquinone (AA), 1-amino-2-methylanthraquinone (1-Am-2-MeA), and 2-methyl-1-nitroanthraquinone (2-Me-1-NA), were determined in Fischer 344 rats and B6C3F₁ mice. The rats were fed 1.0% or 2.0% AA in the diet, 0.12% or 0.24% 1-Am-2-MeA, or 0.06% or 0.12% 2-Me-1-NA; the mice were fed 0.5% or 1.0% AA, 0.03% or 0.06% 1-Am-2-MeA, or 0.03% or 0.6% 2-Me-1-NA. In rats, all three chemicals increased the incidence of hepatocellular neoplasms. 1-Am-2-MeA increased the incidence of renal neoplasms and 2-Me-1-NA increased the incidence of sc fibromas in a dose-related manner. In mice, AA increased the incidence of hepatocellular carcinomas and 2-Me-1-NA increased the incidence of sc hemangiosarcomas. 1-Am-2-MeA did not appear to be carcinogenic in the mouse.

Nephrotoxicity was associated with the feeding of AA to female rats and 1-Am-2-MeA to mice. (11 refs)

- 79-6263 Potential Contamination from Feeding Test Chemicals in Carcinogen Bioassay Research: Evaluation of Single- and Double-Corridor Animal Housing Facilities. (Eng) Sansone, E. B. (Environmental Control and Res. Lab., NCI Frederick Cancer Res. Center, Frederick, MD 21701); Losikoff, A. M. *Toxicol Appl Pharmacol* 50(1): 115-121; 1979.

The magnitude and distribution of chemical contamination from single- and double-corridor animal rooms was determined by adding a tracer chemical, sodium fluorescein, to the granular diet of 200 Fischer F-344 male rats housed in single- and double-corridor rooms of equal size operated under identical protocols. The distribution of chemical contamination was monitored over a 7.5-day period. Differences between the two rooms were statistically indistinguishable ($\alpha = 0.05$) in all comparisons but two: the contamination of the room floors and of the worker's gloves; in both cases, the single-corridor room contamination was greater. The difference between the floor data was attributed to the traffic patterns required by the rooms' configuration; in the presence of confirming findings from any other articles of clothing or animal care and maintenance operations, the glove findings were discounted. Floor contamination outside the vestibule and clean corridor doors suggested that the relative cross-contamination potential of single- or double-corridor facilities was about 6 to 1. If more than one room opened off the vestibule, the ratio could be about 20 to 1. It is suggested that the potential for cross-contamination can be most effectively and most economically reduced by controlling contamination at the source. (5 refs)

- 79-6264 Mutagenic Activity of Rhodamine Dyes and Their Impurities as Detected by Mutation Induction in *Salmonella* and DNA Damage in Chinese Hamster Ovary Cells. (Eng) Nestmann, E. R. (Mutagenesis Section, Environmental and Occupational Toxicology Div., Health Protection Branch, Dept. Natl. Health and Welfare, Ottawa, Ontario, K1A 0L2, Canada); Douglas, G. R.; Matula, T. I.; Grant, C. E.; Kowbel, D. J. *Cancer Res* 39(11): 4412-4417; 1979.

Commercial rhodamine dyes 6G and B were examined for induction of genetic effects using the *Salmonella*/mammalian microsome assay for mutation and Chinese hamster ovary (CHO) cells in vitro for detection of DNA strand breakage. Rhodamine B (0.25-4.0 mg/plate) was mutagenic in *Salmonella* strains TA1538 and TA98 (frameshift mutation) but not in strains TA1535, TA100 (both base substitution mutation) or TA1537 (frameshift mutation). Purified rhodamine B lost most of its mutagenicity while its impurities demonstrated the same extent of mutagenicity as the commercial dye. Rhodamine 6G (7.8-1,000 μ g/plate) was mutagenic in strains TA1538, TA98, TA1537, and TA100. It induced a doubling of revertants at only 3% (7.8 μ g) of the dose required for a doubling by rhodamine B (250 μ g) in strain TA1538. At its max, rhodamine 6G induced a 30-fold increase of revertants in strain TA1538, whereas the max increase induced by rhodamine B was 9-fold. Compared with the commercial dye, purified rhodamine 6G lost 22%-23% of its mutagenicity, but it still induced a 24-fold increase in revertants. Rhodamine 6G (9×10^{-5} M) and rhodamine B (9.6×10^{-4} M) caused damage in single strands of DNA in CHO cells as detected by alkaline sucrose sedimentation. Rhodamine 6G was more toxic than rhodamine B in both the bacterial and mammalian assays. Both dyes required activation by

Aroclor 1254-induced rat liver homogenate (S9) for induction of genetic activity. These results indicate that purified rhodamine 6G is potentially mutagenic while purified rhodamine B shows little mutagenicity. (22 refs)

- 79-6265 Mechanism of Enhancement of Polynucleotide Binding to Cells by Mutagens. (Eng) Noronha-Blob, L. (Lab. Cellular and Molecular Biology, Gerontology Res. Center, Natl. Inst. Aging, Baltimore, MD 21224); Pitha, J. *Biochemistry* 18(15): 3206-3209; 1979.

The mechanism of the enhanced binding of polyuridylyl[poly(U)] to WI-38 human fibroblasts was studied in the presence of compounds known to bind DNA. Fibroblast monolayers exposed to 10 ml of a soln containing 61 μ g/ml poly(U) bound approx 0.2 picogram/cell of polynucleotide, and saturation occurred within a few minutes. When cells were exposed to both poly(U) and proflavine (PF:100 μ g/ml), poly(U) binding was increased 10- to 20-fold. The increase was both time- and PF concentration-dependent. The PF-mediated enhancement was completely abolished by a 10-min wash with saline, and MgCl₂ and NaCl were equally effective. Thus, the PF-augmented binding of poly(U) to the cell surface appeared to be ionic. Enhanced polynucleotide binding was observed only upon simultaneous, not sequential, exposure to poly(U) and PF. The binding of the basic macromolecule diethylaminoethyl-dextran was only slightly enhanced by PF. The binding of poly(U) was not enhanced by ethylenediamine, primaquine, or quinacrine, but it was enhanced by acridine orange, and 9-aminoacridine, and Hoechst 33258; 9-aminoacridine was less effective in this respect than PF. When PF or Hoechst 33258 was attached by firm chemical bonds to the soluble polysaccharide dextran, their ability to enhance the binding of poly(U) to fibroblasts was lost. A model for the enhanced binding of poly(U) is proposed, based on the cooperative formation of stacked complexes of cationic dye located between the cell surface and the bound poly(U). (18 refs)

- 79-6266 Tritiated Thymidine as a Broad Spectrum Initiator in Transplacental Two-Stage Carcinogenesis, with Phorbol as Promoter. (Eng) Armuth, V. (Experimental Biology Unit, Weizmann Inst. Science, Rehovoth, Israel); Berenblum, I. *Int J Cancer* 24(3): 355-358; 1979.

To determine whether [³H]thymidine (HTdR) acts as an initiator in transplacental two-stage carcinogenesis, pregnant BALB/c mice received a single sc injection of 200 μ Ci HTdR on day 15 of gestation. Starting 10 days after birth, the offspring received phorbol (0.25 μ mole 2x/wk x 3, then 0.50 μ mole 2x/wk x 22, ip) for 25 wk and were examined for tumor induction for 18 mo. There was a significant increase in the total tumor incidence (12/27) in the phorbol-treated male offspring of the HTdR-injected mothers compared with controls (1/25, $p < 0.001$). The main constituents of this increase were lung adenomas (7/27) and liver tumors (5/27), but taken separately the increase in incidence of these two types was only of borderline significance. Hepatic tumors were detected in phorbol-treated female offspring but not in their untreated counterparts. The incidences of other kinds of tumors in male and female phorbol-treated offspring were not significantly increased. The direct carcinogenicity of HTdR, both in the mothers and in the offspring, was relatively low or even nonexistent. The results suggest that HTdR could be used as a broad spectrum initiator for transplacental two-stage carcinogenicity studies to determine the organ specificity of different promoting agents. (18 refs)

- 79-6267 Rapid Release of Fibronectin from Human Lung Fibroblasts by Biologically Active Phorbol Esters. (Eng) Keski-Oja, J. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20205); Shoyab, M.; De Larco, J. E.; Todaro, G. J. *Int J Cancer* 24(2): 218-224; 1979.

The ability of several biologically active phorbol esters to release fibronectin from cultured human lung fibroblasts into medium was determined by a sensitive radioimmunoassay technique. The esters released fibronectin from the cells into the medium within 2 hr, producing concomitant changes in cellular morphology. The quantity of fibronectin released was dose-, time- and promoter-dependent. The earliest release of fibronectin occurred within 30 min of onset of incubation. Alterations in membrane topology elicited by the phorbol esters appear to be responsible for the rapid release of fibronectin molecules. (38 refs)

- 79-6268 Effect of Phorbol Ester Tumor Promoters on the Expression of Melanogenesis in B-16 Melanoma Cells. (Eng) Mufson, R. A. (Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032); Fisher, P. B.; Weinstein, I. B. *Cancer Res* 39(10): 3915-3919; 1979.

The effects of phorbol esters on the growth and differentiation of the C3 clone of B16 melanoma cells were studied. B16 cells attained a low basal melanin content 24 hr after plating, then began synthesizing large amounts of pigment upon reaching confluence on day 5. In cultures treated with 8×10^{-8} M 12-O-tetradecanoylphorbol-13-acetate (TPA) 24 hr after plating, the increased synthesis of pigment was delayed for 48 hr. This lag was not due to an effect of TPA on the cellular growth rate or the time at which the cultures reached confluence, and there was no inhibitory effect on cellular cloning efficiency. The escape from TPA-mediated inhibition, which occurred after about 48 hr, was not prevented by the addition of fresh TPA to the medium. Phorbol-12,13-didecanoate (PDD) and mezerein also caused a marked inhibition of melanin synthesis, although escape from inhibition by mezerein, the weaker tumor promoter, was more rapid than that from TPA-mediated inhibition. 4 α -phorbol-12,13-didecanoate, which is not a tumor promoter on mouse skin, did not inhibit melanogenesis. B16 cells were most sensitive to TPA-induced inhibition of melanin synthesis when cells were plated in TPA-containing medium or when the compound was added during the first 24 hr after plating. Melanin synthesis induced by melanin stimulating hormone (MSH) was blocked by TPA added 24 hr in advance of or, to a lesser extent, at the same time as MSH. The TPA sensitivity of the B16 stock cultures declined somewhat with the passage of time. (22 refs)

- 79-6269 The Effect of Phorbol Myristate Acetate on Human Lymphocytes. An Ultrastructural Study. (Eng) Skinner, L. F. (Dept. Pathology, Univ. Saskatchewan, Saskatoon S7N 0W0, Canada). *Exp Mol Pathol* 31(1): 36-43; 1979.

The ability of phorbol myristate acetate (PMA) to agglutinate normal human lymphocytes was compared with that of phytohemagglutinin (PHA), and the ultrastructural changes induced by PMA were studied. Lymphocyte agglutination was first noted microscopically at 1 hr, and by 24 hr agglutinates were evident macroscopically. The ultrastructural findings in the PMA-stimulated lymphocytes after 48 and 72 hr indicated blast transformation of the nucleus, increases in cytoplasm and ribosomes, and occasional "annulate lamellae." Apart from the annulate

lamellae, the changes were generally similar to those observed in PHA-stimulated lymphocytes. The data suggest that the initial action of PMA is on the cell membrane. (11 refs)

- 79-6270 Interaction of the Tumor Promoter 12-O-Tetradecanoylphorbol-13-Acetate with Cells in Mixed-Lymphocyte Culture. (Eng) Mastro, A. M. (Dept. Biochemistry and Biophysics, Pennsylvania State Univ., University Park, PA 16802); Krupa, T. A.; Smith, P. *Cancer Res* 39(10): 4078-4082; 1979.

The effects of 12-O-tetradecanoylphorbol-13-acetate (TPA) on bovine lymphocytes in mixed-lymphocyte reactions (MLR) were studied. Preincubation of cells with TPA for several days prevented them from synthesizing DNA in the MLR and also inhibited blastogenesis. A further 3-day incubation in fresh medium before mixing restored the ability of the cells to undergo the MLR. Although pretreatment of either responding or stimulating cells inhibited DNA synthesis in the MLR, responding cells were most sensitive to TPA treatment. Increasing the ratio of untreated stimulating cells to TPA-treated responders did not overcome the inhibitory effect of TPA on the responders, but the effect of the TPA-treated stimulating cells depended on cell dose. The response of TPA treatment showed some variability from animal to animal. The data are consistent with the idea that TPA acts by changing the cell surface recognition structures and/or indirectly, through activation of a subpopulation of cells, by blocking the proliferative response. (36 refs)

- 79-6271 Differential Response of Myofibrils and 10-nm Filaments to a Cocarcinogen. (Eng) Toyama, Y. (Dept. Anatomy, Sch. Medicine, Univ. Pennsylvania, Philadelphia, PA 19104); West, C. M.; Holtzer, H. *Am J Anat* 156(1): 131-137; 1979.

Multinucleated myotubes containing large numbers of striated myofibrils and longitudinally-oriented 10-nanometer (nm) filaments were treated with the cocarcinogen phorbol-12-myristate-13-acetate (PMA) for 24, 48 or 72 hr. The inhibitory effect of PMA on the accumulation of myofibrils was evident within 24 hr, and by 72 hr virtually all striated myofibrils had disappeared. In contrast, the density of the 10-nm filaments was greatly enhanced in these myofibril-depleted myotubes. These effects were not due to a generalized cytotoxicity, as PMA stimulated the replication of the presumptive myoblasts and fibroblasts present in these cultures. The myotubes assembled a new set of striated myofibrils 24 hr after removal of PMA, and the density of 10-nm filaments diminished proportionately. (12 refs)

- 79-6272 Effects of Phorbol Ester Tumor Promoters in Platelet Aggregation and Platelet Production of Cyclooxygenase Products. (Eng) Mufson, R. A. (Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY 10032); Kulkarni, P.; Eakins, K. E.; Weinstein, I. B. *Cancer Res* 39(9): 3602-3606; 1979.

An attempt was made to correlate the structure-activity relationships previously established for the tumor-promoting activity of phorbol esters with their platelet-aggregating activity. The tumor promoters 12-O-tetradecanoylphorbol-13-acetate (TPA),

phorbol-12,13-didecanoate, and mezerein, in the range of 10^{-8} M, caused aggregation of washed rabbit platelets. The lag time between the addition of tumor promoters and the onset of aggregation was inversely proportional to the concentration of the compounds. 4 α -Phorbol-12,13-didecanoate, which is inactive as a tumor promoter, did not induce platelet aggregation, and 4-O-methyl-12-O-tetradecanoylphorbol-13-acetate, which is a weak tumor promoter, had low activity in this assay. Arachidonic acid also caused platelet aggregation. Arachidonic acid-induced aggregation was rapid, reversible, and accompanied by the production of thromboxane A_2 -like activity, as determined by bioassay on rabbit aorta and celiac artery strips. This aggregation was blocked by the cyclooxygenase inhibitor indomethacin. TPA-induced aggregation, however, was slow and irreversible. It was not accompanied by production of thromboxane A_2 -like activity and was not blocked by indomethacin. TPA-induced aggregation was accompanied by the enhanced production of a vasoactive material that contracted only rabbit celiac artery and, in contrast to thromboxane A_2 , was stable for 10 min at 37 C. This material was not ADP or 5-hydroxytryptamine. The results indicate that the structural requirements of diterpenes for tumor promotion are similar to those for platelet-aggregating activity. The generation of prostaglandin synthetase (cyclooxygenase) products does not appear to be required for phorbol ester-induced aggregation. The latter is accompanied by the production of an unidentified vasoactive material that may be related to the mechanism of aggregation. (20 refs)

- 79-6273 The Effect of a Tumor Promoter, 12-O-Tetradecanoyl-phorbol-13-acetate (TPA), on Sister-Chromatid Exchange Formation in Cultured Chinese Hamster Cells. (Eng) Loveday, K. S. (Genetics Div., Mental Retardation Center, Children's Hosp. Medical Center, Boston, MA 02115); Latt, S. A. *Mutat Res* 67(4): 343-348; 1979.

At 0.3-3.0 μ g/ml, the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) did not increase the sister-chromatid exchange (SCE) frequency in either Chinese hamster ovary (CHO) or lung (V79) cells cultured in the presence of 2×10^{-5} or 1×10^{-4} M 5-bromodeoxyuridine. Moreover, TPA did not alter the induction of SCE's in CHO cells by mitomycin C (0.03 μ g/ml) during the first three cycles following the addition of the alkylating agent. These SCE induction data do not support the hypothesis that tumor promotion by TPA depends on the enhancement of mitotic recombination. (25 refs)

- 79-6274 Prostaglandin E and F Levels in Mouse Epidermis are Increased by Tumor-promoting Phorbol Esters. (Eng) Ashendel, C. L. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Boultwell, R. K. *Biochem Biophys Res Commun* 90(2): 623-627; 1979.

Prostaglandins E (PGE) and F (PGF) levels were determined by radioimmunoassay in female CD-1 mouse epidermis after topical application of phorbol esters. Peak PGE levels (six times basal levels) were detected at 6 and 24 hr after treatment with 12-O-tetradecanoylphorbol-13-acetate (TPA; 17 nanomoles). PGF levels also peaked twice, increasing threefold at 9 hr and tenfold by 72 hr after TPA treatment. The phorbol effect on PG levels lasted for 5-7 days. The increase in PGE levels was dose dependent. The activities of various phorbols for increasing PGE and PGF levels were TPA > phorbol-12,13-didecanoate > phorbol-12,13-dibenzoate > phorbol-12,13-diacetate \approx phorbol. Various doses of

the nonsteroidal anti-inflammatory drugs indomethacin, flufenamic acid, and naproxen were applied topically to mice 2 hr prior to treatment with 17 nanomoles of TPA and epidermal PGE levels were measured 6 hr after TPA. The doses of indomethacin, flufenamic acid, and naproxen that inhibited the TPA-increased PGE levels by 50% were 46, 110, and 135 nanomoles, respectively. For the five phorbol compounds tested, the increased epidermal PG levels paralleled ornithine decarboxylase induction and increased DNA synthesis and skin papilloma formation in initiated mice. These results support the hypothesis that PGs are involved in the mechanism of action of tumor-promoting phorbol esters. (19 refs)

- 79-6275 Ornithine Decarboxylase Activity, Cell Proliferation, and Tumor Promotion in Mouse Epidermis In Vivo. (Eng) Marks, F. (German Cancer Res. Center, Inst. Biochemistry, Im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Bertsch, S.; Furstenberger, G. *Cancer Res* 39(10): 4183-4188; 1979.

The effect of different phorbol esters and of mechanical treatment on the activity of ornithine decarboxylase in mouse epidermis was investigated in vivo. The strong tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA), as well as the weak promoters phorbol dibenzoate and the TPA analog 12-O-tetradeca-2-cis,4-trans-6,8-tetradecanoylphorbol-13-acetate strongly increased the activity of the enzyme and the intraepidermal level of putrescine, with a max at 5 hr after application, when applied in doses that evoke comparable proliferative and irritant responses in skin. The 4-O-methyl ether of TPA did not show such effects. Mechanical removal of the uppermost horny layer led to an increase in ornithine decarboxylase activity after 4-8 hr, while skin massage showed only a minute effect under conditions in which both treatments exhibit about the same mitogenic efficiency. Rubbing did not promote tumor development in this study, and the same has been previously found to be true for massage. After skin massage, ornithine decarboxylase induction was unaffected by treatments that alter the cyclic AMP level in epidermis (inhibition of phosphodiesterase, β -adrenergic stimulation, and injection of dibutyl cyclic AMP) or by the injection of epidermal G chalone. The results indicate that no clear-cut correlation exists between epithelial cell proliferation, development of hyperplasia, and tumor promotion on the one hand and activation of epidermal ornithine decarboxylase on the other. (26 refs)

- 79-6276 Dynamics of Neoplastic Development in Carcinogen-exposed Tracheal Mucosa. (Eng) Terzaghi, M. (Biology Div., Oak Ridge Natl. Lab., PO Box Y, Oak Ridge, TN 37830); Nettesheim, P. *Cancer Res* 39(10): 4003-4010; 1979.

An in vitro assay of the formation of epithelial foci (EF) was used to study cellular changes occurring in the tracheal epithelium of specific-pathogen-free female Fischer 344 rats exposed over a 4-wk period to wax pellets containing 12-O-tetradecanoylphorbol-13-acetate (TPA, 100 μ g) or dimethylbenz(a)anthracene (DMBA, 165 μ g). Cell suspensions from each trachea were seeded into culture dishes, and the number of EF was scored 1 mo later. No EF were seen in cultures of normal tracheal cells or those exposed to TPA. In 80%-90% of cultures from tracheas exposed to DMBA up to 4 mo previously, 3-4 EF were found per culture, and in those from tracheas exposed to DMBA 4-8 mo previously, the number of EF per culture increased three- to fivefold. During the 80 mo after DMBA exposure, EF that could be subcultured increased from

53% to 84%, and EF that could be subcultured and grown in soft agar increased from 23% to 57%. The frequency of EF that could not be subcultured dropped from 47% to 16%, and the relative frequency of EF that could be subcultured but would not grow in soft agar remained constant. The data are consistent with a gradual conversion of epithelial focus-forming units (EFFUs) with limited growth capacity to EFFUs with neoplastic growth capacity as a function of time after carcinogen exposure. At 8 mo, 80% of DMBA-exposed tracheas contained cells with neoplastic potential, suggesting that, if left in the host animals, only a fraction of these cells would actually succeed in establishing malignant tumors. (29 refs)

79-6277 Effects of Phorbol Ester Tumor Promoters on Arachidonic Acid Metabolism in Chick Embryo Fibroblasts. (Eng) Mufson, R. A. (Div. Environmental Sciences and Cancer Center/Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168 St., New York, NY 10032); DeFeo, D.; Weinstein, I. B. *Mol Pharmacol* 16(2): 569-578; 1979.

The phorbol ester tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA: 10^{-7} - 10^{-9} M) caused a rapid (1-3 hr after addition) release of arachidonic acid and prostaglandins E₂ and F_{2 α} from chick embryo fibroblasts. This effect was inhibited by cycloheximide and puromycin. Prostaglandin release was more sensitive to inhibition than was arachidonic acid release. Indomethacin, a cyclooxygenase inhibitor, completely blocked TPA-induced prostaglandin synthesis and slightly enhanced arachidonic acid release. Despite the complete suppression of prostaglandin synthesis, indomethacin caused only a 20-30% inhibition of TPA induction of plasminogen activator. Phorbol-12,13-didecanoate, phorbol-12,13-dibenzoate and mezerein were also potent inducers of arachidonic acid and prostaglandin release, while phorbol and 4 α -phorbol didecanoate were inactive. All-*trans*-retinoic acid (10^{-5} - 10^{-6} M) inhibited TPA-induced arachidonic acid and prostaglandin release; retinyl palmitate and β -carotene were less effective inhibitors. The effects of the phorbol compounds and retinoids on arachidonic acid release in this cell culture system correlate with their known effects on tumor promotion in mouse skin. Deacylation of membrane phospholipids may, therefore, be an important contributing factor in the action of this class of tumor promoters. (28 refs)

79-6278 Phorbol Ester Induced Prostaglandin Synthesis and [³H]-TPA Metabolism by TPA-sensitive and TPA-resistant Friend Erythroleukemia Cells. (Eng) Yamasaki, H. (Unit Chemical Carcinogenesis, International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon Cedex 2, France); Mufson, R. A.; Weinstein, I. B. *Biochem Biophys Res Commun* 89(3): 1018-1025; 1979.

The effect of the potent mouse skin tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) on the release of [³H]arachidonic acid and [³H]prostaglandin synthesis in TPA-resistant and TPA-sensitive clones of Friend erythroleukemia cells (FELC) is reported, along with the metabolism of [³H]TPA in these clones. TPA caused the release of arachidonic acid and prostaglandins E₂ and F_{2 α} from FELC. This effect was not seen with a subclone that is resistant to both TPA-induced inhibition of differentiation and TPA-induced adhesion. TPA-sensitive and TPA-resistant clones metabolized [³H]TPA and phorbol-13-monoacetate [P(13)A] at the same rate. P(13)A had no effect on the differentiation or adhesion of FELC. Together with previous

findings, these results suggest that TPA-induced changes in membrane lipid metabolism are closely linked to the effects of TPA on growth, differentiation, and adhesion. The resistance of a subclone of FELC to TPA appears to be at the level of membrane action rather than the metabolism of TPA. (21 refs)

79-6279 Effects of Dietary Fat on Hepatic Mixed-Function Oxidases and Hepatocellular Carcinoma Induced by Aflatoxin B₁ in Rats. (Eng) Newberne, P. M. (Room E18-613, Massachusetts Inst. Technology, Cambridge, MA 02139); Weigert, J.; Kula, N. *Cancer Res* 39(10): 3986-3991; 1979.

The effects of dietary beef fat (13% or 28% of diet) and corn oil (2%, 15%, or 30%) on the induction of hepatocarcinomas in male Sprague-Dawley rats that received intragastric doses of aflatoxin B₁ (AFB: 7 mg/kg as a single dose or 25 μ g/day for 5 or 15 days) were studied. Rats fed beef fat had increased liver fat concentrations (4.61% and 4.24% of body wt in 28% and 13% beef fat groups, respectively) and increased mortality due to acute AFB toxicity (63.3% and 83.8% in 28% and 13% groups, respectively) than did those given corn oil. The resting microsomal enzyme activity levels increased sequentially in all rats over a 3-wk period, the increases in many cases being significantly higher ($p \leq 0.05$) in the rats given corn oil than in those given beef fat. In rats exposed to AFB, corn oil also significantly enhanced the induction of enzyme activity by AFB, compared with induction in those given beef fat. Hepatic tumor incidence was higher in rats fed the high-corn oil diet during and after AFB exposure (100%) and in those fed the high corn oil diet after AFB exposure (66%) than in those fed beef fat, whether or not the diets were fed during AFB exposure (51%-53%, $p = 0.02$). The data suggest that corn oil may act as a tumor promoter through microsomal enzyme induction and AFB activation. (45 refs)

79-6280 Biochemical Studies During Aflatoxin B₁-induced Liver Damage in Rats Fed Different Levels of Dietary Protein. (Eng) Mirmomeni, M. H. (Biochemistry Dept., Univ. Kermanshah, Kermanshah, Iran); Suzangar, M.; Wise, A.; Messripour, M.; Emami, H. *Int J Cancer* 24(4): 471-476; 1979.

The biochemical aspects of liver damage induced by aflatoxin B₁ (AFB: 2 mg/kg in the diet) in male Sprague-Dawley rats fed high (HP)- or low (LP)-protein diets were studied. AFB enhanced and subsequently inhibited the growth of rats fed the HP diet but had no effect on the growth of those given the LP diet. In rats fed the HP diet, AFB increased lactic dehydrogenase (LDH) levels by 82% and 210% at 16 and 24 wk, respectively, over the levels in HP-fed rats not receiving AFB. At 24 wk, the HP-AFB-fed rats showed increases of 114%, 45%, and 76% in alkaline phosphatase (AP), SGOT, and SGPT levels, respectively, over the levels in HP-fed rats not given AFB. SGPT was increased 59% over control (LP diet without AFB) at 24 wk in the rats given the LP diet with AFB. Aflatoxin M₁ (AFM) and aflatoxin P₁ (AFP) excretion tended to be lower in the HP than in the LP rats. AFB feeding increased kidney wt, but not liver wt, in relation to body wt, especially in HP-fed rats. The dietary protein level did not significantly affect the appearance of the liver, but AFB caused degeneration and necrosis in LP- and HP-fed rats and the development of hyperplastic nodules in HP-fed rats. It is concluded that LDH, AP, and the ratio of urinary excretion of AFM to AFP could be useful tests for the diagnosis of AFB-induced precancerous liver changes in humans. (no refs)

- 79-6281 Aflatoxigenic Potential of Dried Figs, Apricots, Pineapples, and Raisins. (Eng) Morton, S. G. (Dept. Biology, Virginia Commonwealth Univ., Richmond, VA 23284); Eadie, T.; Llewellyn, G. C. *J Assoc Off Anal Chem* 62(4): 958-962; 1979.

Dried figs, apricots, raisins, and pineapples were evaluated with respect to their potential for contamination by aflatoxins. Spores from three aflatoxigenic strains were applied to the surfaces of the dried fruits, half of which had been autoclaved prior to inoculation. Mold growth was monitored daily for 45 days, after which the aflatoxin present was extracted and analyzed. No mold growth or sporulation of aflatoxin was found on any of the 18 raisin samples, whereas extensive mold growth was observed on all pineapple slices, the amount of aflatoxin depending on fungus strain. None of the cooked figs showed mold growth or sporulation, whereas all uncooked figs did. None of the figs produced any aflatoxin B₂. All of the cooked apricots produced some aflatoxin, the amounts of B₁ and G₁ being generally equal. The one set of uncooked apricots that produced aflatoxins produced only small amounts of G₁ and even lesser amounts of B₁. The overall potential for toxin production in the dried fruit was apricot > fig > pineapple > raisin. Among the cooked substrates, the order was apricot > pineapple > fig > raisin. For raw dried fruit, the ranking was fig > pineapple > apricot > raisin. (22 refs)

- 79-6282 Metabolic Activation of Polycyclic Aromatic Carcinogens: A Theoretical Study. (Eng) Umans, R. S. (Dept. Chemistry, Wellesley Coll., Wellesley, MA 02181); Koruda, M.; Sardella, D. J. *Mol Pharmacol* 16(2): 633-642; 1979.

Huckel molecular orbital calculations were performed on a series of polycyclic aromatic hydrocarbons (PAH) to obtain bond localization energies and π -electron stabilization energies for the reaction sequence through which the "bay region" diol epoxide is formed. These calculations suggest that carcinogenic PAH and noncarcinogenic PAH may exhibit different behavior at three points in the sequence. The highest localization energies for formation of the initial epoxide are exhibited exclusively by a block of noncarcinogenic PAH, suggesting that they may form only minimal amounts of the initial dihydrodiol. Of the remaining PAH, the carcinogens generally exhibit greater π -electron stabilization than do noncarcinogens following opening of both the initial epoxide and the diol epoxide rings, possibly indicating more facile production of the initial dihydrodiol and of the final biomolecule adduct. The relative potencies of the 12 carcinogenic PAH considered, as measured by the Iball Index, can be satisfactorily reproduced (correlation coefficient = 0.90) through an equation combining indices for formation of the initial epoxide and for π -electron stabilization of its ring-opened cation. (32 refs)

- 79-6283 Relationships Between Carcinogenicity and Theoretical Reactivity Indices in Polycyclic Aromatic Hydrocarbons (Letter to Editor). (Eng) Osborne, M. R. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Buckinghamshire HP8 4SP, England). *Cancer Res* 39(11): 4760-4761; 1979.

An earlier paper proposed that the parameter Q_b , which represents the positive charge at the bay-region position for various hydrocarbons, was negatively correlated with the carcinogenicity of the compound. However, the use of Q_b gave rise to a number of false positives, ie, compounds which have a low Q_b value but are not

carcinogenic. These anomalies derive from the fact that in the presumed diol-epoxide carbonium ions from these hydrocarbons, the positive charge resides largely at two or three positions instead of being delocalized all around the aromatic nucleus. In response to this paper, it is proposed instead that the ease of carbonium ion formation is best estimated by the uniformity of distribution around the molecule as a whole. A parameter which expresses this uniform distribution of charge is σ/a_o , the sum of the nonbonding molecular orbital coefficients. This quantity is as easy to calculate as is Q_b . It varies from 1.0 for a localized positive charge to a little more than 3 for ions derived from the highly delocalized tribenzo(a)pyrenes. The carcinogenic potencies of 39 hydrocarbons were plotted against σ/a_o for the most reactive diol-epoxides they would be expected to form. There was a good correlation between carcinogenicity and σ/a_o , and the anomalies encountered with Q_b were largely removed. The criterion $\sigma/a_o > 2.6$ appears to distinguish carcinogens from noncarcinogens with few exceptions. (6 refs)

- 79-6284 Cigarette Smoke Inhalation Studies in Inbred Syrian Golden Hamsters. (Eng) Bernfeld, P. (Bio-Res. Consultants, 9 Commercial Ave., Cambridge, MA 02141); Homburger, F.; Soto, E.; Pai, K. J. *J Natl Cancer Inst* 63(3): 675-689; 1979.

Inbred Syrian golden hamsters from strain B10 15.16, which is susceptible to laryngeal carcinogenesis by cigarette smoke inhalation, were exposed to smoke from four types of cigarettes at two dose levels. Fifty-seven hamsters were exposed to smoke from an all-tobacco cigarette during two 12-min periods (actual smoke exposure 27 sec out of each minute) for ≥ 59 wk at a smoke concentration of 22%; 47.4% developed laryngeal cancer, and in 36.8% of the exposed animals, the cancer was invasive. At a smoke concentration of 11%, 6.8% of exposed hamsters developed invasive carcinoma. Smoke from cigarettes containing only Cyrel (a tobacco supplement) induced no carcinomas. Replacement of part of the tobacco by Cyrel resulted in a reduction of tumor induction proportionate to the amount of Cyrel in the cigarette. Tar deposition in lungs and larynxes was determined by means of a marker, decachlorobiphenyl, added to the cigarettes. Admixture of Cyrel to cigarettes reduced tar deposition in the respiratory tract. However, the amounts of tar deposited in the larynx when 100% Cyrel was smoked were still significant, even though no carcinomas were observed. Other dose-related changes observed in the smoke-exposed hamsters were laryngeal papillomas, laryngeal epithelial hyperplasia, tracheal epithelial hyperplasia, and metaplasia and accumulation of alveolar macrophages. It is concluded that smoke inhalation studies in unprimed, nose-breathing animals are unlikely to yield lung cancer, although such studies do cause laryngeal cancer under rigorous conditions such as those used in this study. - 79-6285 Tumors and Hyperplastic Lesions in Syrian Hamsters Following Transplacental and Neonatal Treatment with Cigarette Smoke Condensate. (Eng) Nicolov, I. G. (Lab. Chemical Carcinogenesis, Inst. Oncology, Medical Acad., Sofia 1156, Bulgaria); Chernozemsky, I. N. *J Cancer Res Clin Oncol* 94(3): 249-256; 1979.

Cigarette smoke condensate (CSC) was tested for both transplacental carcinogenicity and carcinogenicity in neonates. CSC in olive oil was injected into adult outbred Syrian hamsters on the 10th-14th day of gestation (total dose 1.5-2.5 mg/g, ip) and

also in 12- to 14-day-old animals (total dose 0.5-1.5 mg/animal, sc). Following 15-25 mo of observation, benign and malignant neoplasms were found in 2/58 animals treated during pregnancy, in 17/51 transplacentally exposed offspring; and in 5/53 neonatally treated hamsters. In the last two groups, females developed neoplasms more frequently than males (46.2% vs 20% in offspring; 17.4% vs 3.3% in animals treated as neonates). Tumors were most frequently encountered in the adrenal glands, pancreas, female sex organs, and liver. Polycystic liver disease occurred in 86% of animals exposed to CSC transplacentally, 79% of those treated as neonates, and 28% of those serving as controls. No tumors were encountered in controls. The results indicate that CSC produces tumors in transplacentally and neonatally exposed hamsters, particularly females. (22 refs)

- 79-6286 Testing of Some Permitted Food Colours for the Induction of Gene Conversion in Diploid Yeast. (Eng) Sankaranarayanan, N. (Div. Radiological Protection, Bhabha Atomic Res. Center, Trombay, Bombay 400085, India); Murthy, M. S. *Mutat Res* 67(4): 309-314; 1979.

Twelve food colors used in India and elsewhere were tested for their ability to induce mitotic gene conversion in the diploid yeast, *Saccharomyces cerevisiae*. None of these substances induced mitotic gene conversion in yeast treated in either stationary-phase or log-phase culture. There was also no significant cell killing or inhibition of cell division, and the absence of such effects was not due to a lack of penetration of the dye into the cells. The results do not agree with the results of some genotoxicity tests conducted with microorganisms and mammalian cell systems, indicating the need for further testing. (18 refs)

- 79-6287 Photocarcinogenesis by Methoxypsoralen, Neutral Red and Proflavine. (Eng) Santamaria, L. (Istituto di Patologia Generale "C. Golgi", Centro Profilassi Prevenzione Diagnosi e Cura dei Tumori, Univ. Pavia, Pavia, Italy); Arnabaldi, A.; Daffara, P.; Bianchi, A. *Boll Chim Farm* 118(7): 356-362; 1979.

The potential tumorigenic effects of 8-methoxypsoralen (8-MOP: 5 µg), neutral red (NR: 100 µg), and proflavine (PF: 50 µg) all given topically 2x/wk in combination with fractionated exposure to long UV (UVA) or visible light (NR and PF) were studied in female Swiss albino mice. The mice were exposed to UVA or visible light 60 min for 15, 30, 45 or 60 min. All groups showed erythema phototoxicity 10-12 hr after irradiation. Tumors developed in all groups and included mammary adenocarcinomas (with lung metastases), mixed carcinosarcomas, lymphomas (with liver metastases), and adenocarcinoma of the thyroid (NR group). No tumors were detected in the area painted with the drugs. Forty-three percent of animals treated with 8-MOP and UVA developed tumors by the 60th wk after initial treatment with onset beginning at the 25th wk. In those treated with NR and visible light, 20% developed tumors by the 50th wk with onset at the 39th wk. In those treated with PF and visible light, 25% had tumors at the 60th wk with onset at the 29th wk. None of the control groups showed tumor development except for the group treated with UVA alone; in this group, 5/40 mice developed carcinomas. It appears that UVA with 2.6% of fluence at 313 nm is a long-term carcinogenic agent. Although the results indicate that there is an oncogenic risk in photochemotherapy for the treatment of skin diseases and oral and genital forms of herpes simplex virus infection, it is emphasized that this treatment has been used for years without any evidence

of an increase in cancer incidence in treated patient groups. (34 refs)

- 79-6288 Use of Hamster Hepatocytes to Metabolize Carcinogens in an In Vitro Bioassay. (Eng) Pooley, J. A. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701); Raineri, R.; Pienta, R. J. *J Natl Cancer Inst* 63(2): 519-524; 1979.

To provide metabolic activation of carcinogens that may more closely resemble that occurring in vivo, intact functional Syrian golden hamster hepatocytes were used to supplement the metabolic capacity of a hamster embryo cell transformation system. Basal levels of aryl hydrocarbon hydroxylase (AHH) were 20-fold greater and epoxide hydrolase (EH) activity was >100-fold higher in hepatocytes than in embryo cells. Induction of AHH with benz(a)anthracene was 7-fold higher and induction with 3-methylcholanthrene was 20-fold higher in hepatocytes than in embryo cells. Lethal x-irradiation of the hepatocytes had little effect on basal or induced levels of AHH or EH. The N-hydroxylase and deacetylase activities in hamster hepatocytes were 450 and 1,000 times greater, respectively, than those previously determined for hamster embryo cells. Embryo cells were treated with diethylnitrosamine, 2-nitrofluorene, or 4-aminoazobenzene in the presence and absence of lethally irradiated hepatocytes. No transformation was observed when the target cells were treated with these chemicals alone. However, when the target cells were treated with the carcinogens in the presence of hamster hepatocytes, transformation was observed with all three compounds. Thus, hepatocytes appear to metabolize these carcinogens to a form that is either biologically active or able to be activated further by the hamster embryo cells. (22 refs)

- 79-6289 The Formation of Dihydrodiols by the Chemical or Enzymic Oxidation of 7-Hydroxymethyl-12-methylbenz(a)anthracene and the Possible Role of Hydroxymethyl Dihydrodiols in the Metabolic Activation of 7,12-Dimethylbenz(a)anthracene. (Eng) Macnicoll, A. D. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JB, England); Burden, P. M.; Ribeiro, O.; Hewer, A.; Grover, P. L.; Sims, P. *Chem Biol Interact* 26(2): 121-132; 1979.

An attempt was made to identify the dihydrodiols formed from 7-hydroxymethyl-12-methylbenz(a)anthracene (HM-MBA) by rat liver microsomal fractions, mouse skin in short-term organ culture, and chemical oxidation in an ascorbic acid/ferrous sulfate/EDTA system by a combination of thin-layer chromatography and high-pressure liquid chromatography. The 3,4-, 8,9-, and 10,11-dihydrodiols were formed in all three systems. The 5,6-dihydrodiol was formed by the rat liver microsomal fractions and by chemical oxidation, but not by the mouse skin in short-term organ culture. The possible role of hydroxymethyl dihydrodiols in the in vivo metabolic activation of 7,12-dimethylbenz(a)anthracene (DMBA) in mouse skin was studied with the use of Sephadex LH-20 column chromatography. The results show that the hydrocarbon-nucleic acid products formed following the treatment of mouse skin in vivo with [³H]DMBA are not the same as those formed following the treatment of mouse skin under the same conditions with either 7-HM-MBA or 7-methyl-12-hydroxymethylbenz(a)anthracene. (20 refs)

- 79-6290 Photooxidation Products of 7,12-Dimethylbenz[a]anthracene. (Eng) Wood, J. L. (Dept. Biochemistry, Univ. Tennessee, Center Health Sciences, Memphis, TN 38163); Barker, C. L.; Grubbs, C. J. *Chem Biol Interact* 26(3): 339-347; 1979.

The main products of the photooxidation of 7,12-dimethylbenz[a]anthracene (DMBA) in aqueous solutions by photooxidation induced by laboratory lighting were characterized by high performance liquid chromatograms (HPLC), UV and mass spectrograms, and by comparisons with authentic samples in an effort to determine whether or not photooxidation could be a factor in studies of hydrocarbon metabolism and their interactions with tissue constituents. The products identified were the 7,12-epidioxy-7,12-dihydro-7,12-dimethyl-, 7,12-dione, 7-hydroxymethyl-12-methyl-, 12-hydroxymethyl-7-methyl-, 7-formyl-12-methyl-, 12-formyl-7-methyl-, and 12-hydroxy-12-methyl-7-one derivatives of benz[a]anthracene. The HPLC profile of products was similar to that obtained from oxidation of DMBA by "one-electron" reagents, singlet oxygen, or liver microsomal metabolism. The present results, taken together with those of other studies, suggest that the mechanism of photooxidation involves the generation of singlet oxygen by a photodynamic effect of DMBA. None of the products was found to be photosensitizing, however, and none was oxidized when dispersed in 10% methanol in water medium. Although it has been established that photooxidation could interfere with the results of hydrocarbon metabolism studies, a current literature review indicates that most investigators are taking this factor into account. (25 refs)

- 79-6291 Evidence for Translational Control of the Binding of 7,12-Dimethylbenz(a)anthracene to DNA of Murine Epidermal Cell in Culture. (Eng) Shoyab, M. (Meloy Labs., Inc., 6715 Electronic Drive, Springfield, VA 22151). *Chem Biol Interact* 25(2/3): 289-301; 1979.

The effects of various aryl hydrocarbon hydroxylase (AHH) inhibitors, antioxidants, inhibitors of DNA, RNA, and protein synthesis, and protease inhibitors on the binding of [7,12-³H]dimethylbenz[a]anthracene ([³H]DMBA) to DNA of murine epidermal cells in culture have been investigated. 7,8-Benzoflavone, 5,6-benzoflavone, and metyrapone (inhibitors of AHH) and the antioxidants butylated hydroxyanisole and butylated hydroxytoluene efficiently reduced the binding of [³H]DMBA to cellular DNA. Inhibitors of DNA and RNA synthesis did not affect this process, whereas inhibitors of protein synthesis (eg, cycloheximide) suppressed the binding of [³H]DMBA to cellular DNA. Protease inhibitors *p*-tosylamide-2-phenyl-chloromethyl ketone and *p*-tosyl-L-lysine chloromethyl ketone also reduced the interaction between DMBA and DNA. These results are consistent with previous findings that the binding of polycyclic aromatic hydrocarbons to cellular DNA depends on continuous protein synthesis but does not require DNA and RNA synthesis. Thus, the binding of DMBA to epidermal DNA appears to be regulated at the translational level; further regulation at the posttranslational level is also possible. (50 refs)

- 79-6292 Transformation of Feline Embryo Cells in Culture by a Chemical Carcinogen. (Eng) Rhim, J. S. (Lab. Cellular and Molecular Biology, NCI, NIH, Bethesda, MD 20205); Nelson-Rees, W. A.; Essex, M. *Int J Cancer* 24(3): 336-340; 1979.

A feline embryo cell line was treated in vitro with 0.1 or 0.01 µg/ml 7,12-dimethylbenz(a)anthracene (DMBA) for 7 days. Mor-

phological alterations, similar to those observed with feline sarcoma virus in feline embryo cells, were noted 45 days after DMBA treatment. However, this alteration was unstable and the cells reverted to normal-appearing epithelial-like cells after further subcultivation. The DMBA-treated cells formed colonies in soft agar, while the control cells treated with dimethylsulfoxide did not. One of these colonies was isolated and further treated with DMBA (0.01 µg/ml for 7 days), which resulted in stable morphological alterations. The DMBA-altered clone line had an increased growth rate, formed colonies in soft agar with high efficiency, and formed larger cell aggregates and grew in this aggregate form when suspended above an agar base. However, no progressively growing tumors were produced when cells were inoculated into nude athymic mice. The transformed lines were negative for feline oncornavirus-associated cell membrane antigen. The author concludes that the transition of a normal cell to a neoplastic one is reflected by a complex array of phenotypic changes and that the malignant and transformed phenotypes may be under separate genetic control or may represent a step-wise progression. - 79-6293 The Association of Bacterial Mutagenicity of Hydrocarbon-derived 'Bay-Region' Dihydrodiols with the Iball Indices for Carcinogenicity and with the Extents of DNA-binding on Mouse Skin of the Parent Hydrocarbons. (Eng) Bartsch, H. (International Agency Res. Cancer, 150 cours Albert Thomas, 69372 Lyon, France); Malaveille, C.; Tierney, B.; Grover, P. L.; Sims, P. *Chem Biol Interact* 26(2): 185-196; 1979.

The mutagenicities of benz(a)anthracene, 7-methylbenz(a)-anthracene, 7,12-dimethylbenz(a)anthracene, 3-methylcholanthrene, and benzo(a)pyrene together with those of their trans-dihydrodiols thought to be precursors of the biologically active bay-region vicinal diol epoxides, were examined in assays with *Salmonella typhimurium* TA100 using postmitochondrial supernatant fractions prepared from the livers of 3-methylcholanthrene-treated rats. The mutagenic activities were compared with: (1) the extents of reaction of the hydrocarbons (HC's) with mouse skin DNA, (2) the carcinogenicities of the HC's expressed as Iball indices, and (3) the activities of the HC's as tumor-initiating agents on mouse skin. Close positive associations were found between the microsome-mediated mutagenicities of the dihydrodiols that could yield bay-region diol epoxides and (1) the extents of reaction with DNA in HC-treated mouse skin and (2) the carcinogenic potencies of the parent HC's. Although these correlations are not perfect, the mutagenic activities of the HC's themselves in microsome-mediated assays with *S. typhimurium* show no correlation with their extents of DNA binding on mouse skin and a poor correlation with activities as initiating agents. These comparisons also indicated that there is a statistically significant positive correlation between carcinogenicity and the in vivo DNA binding on mouse skin treated with the HC's. There are differences in the metabolic pathways by which polycyclic HC's are activated in vivo and in vitro. (41 refs)

- 79-6294 Caffeine Inhibits the Binding of Dimethylbenz(a)anthracene to Murine Epidermal Cells DNA in Culture. (Eng) Shoyab, M. (Meloy Labs., Inc., 6715 Electronic Drive, Springfield, VA 22151). *Arch Biochem Biophys* 196(1): 307-310; 1979.

The effect of caffeine on the binding of dimethylbenz(a)anthracene (DMBA) to murine epidermal cell (MEC) DNA was studied in vitro. Caffeine suppressed the binding of DMBA to

MEC DNA while barely affecting the cell number or total DMBA associated with the cells. The degree of suppression was concentration-dependent, being 20% at 5 mM caffeine and approx 50% at 1 mM caffeine. Theophylline also inhibited the binding of DMBA to MEC DNA, although to a lesser extent than caffeine. Binding was not significantly affected by other chemical analogs of caffeine such as theobromine, xanthine, hypoxanthine, and uric acid. Dibutyryl cyclic AMP also did not significantly affect the binding of DMBA to MEC DNA, suggesting that caffeine and theophylline inhibited binding by a mechanism independent of cyclic AMP. The antitumorigenic effects of caffeine may be related to the ability of caffeine to inhibit the binding of active metabolites of carcinogens to the genetic material of cells. (32 refs)

- 79-6295 Polyadenylate-Polyuridyate Enhancement of 7,12-Dimethylbenzanthracene Skin Carcinogenesis. (Eng) Stenback, F. (Dept. Pathology, Univ. Kuopio, SF-70101 Kuopio, Finland); Curtis, G.; Ryan, W. *Experientia* 35(9): 1232-1233; 1979.

The effect of stimulation of the immune response by polyadenylate-polyuridyate (Poly AU) on 7,12-dimethylbenzanthracene (DMBA)-induced skin tumor formation was studied in female Swiss mice. The administration of Poly AU (100 µg/day, 5 days, ip) prior to topical DMBA application (100 µg) significantly increased skin tumor formation ($p < 0.02$), whereas the increase in skin tumor formation observed when Poly AU was administered after DMBA application was not significant. Most tumors were papillomas, and malignant tumors were seen only in animals receiving Poly AU after DMBA. The enhancement of tumor formation seen when the immune response was stimulated before carcinogen administration may be due to heightened carcinogen antibody formation. (14 refs)

- 79-6296 Aryl Hydrocarbon Hydroxylase in a Stable Human B-Lymphocyte Cell Line, RPMI-1788, Cultured in the Absence of Mitogens. (Eng) Freedman, H. J. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY 14263); Gurtoo, H. L.; Minowada, J.; Paigen, B.; Vaught, J. B. *Cancer Res* 39(11): 4605-4611; 1979.

Various parameters influencing aryl hydrocarbon hydroxylase (AHH) activity and inducibility were studied in a stable, immunologically defined human B-lymphocyte cell line (RPMI-1788) in long-term culture that shows high basal and inducible (AHH) activity in the absence of mitogenic prestimulation. This allowed attainment of enzyme levels and inducibility ratios comparable to those previously reported for fresh, mitogen-activated human lymphocytes. Dibenz(a,h)anthracene, at an optimal concentration of 0.3 µM and an optimal exposure time of 24 hr, was 30 times more potent an inducer than 1,2-benzanthracene. Maximal basal and induced enzyme activities and cell viability occurred at 48 hr of culture while the cell viability frequently declined by 72 hr of culture. Phytohemagglutinin M (200 µg/ml) and concanavalin A (40 µg/ml), which were not obligatory for AHH expression, enhanced AHH activity while, at the same time, decreasing the number of viable cells per culture. However, combinations of phytohemagglutinin and concanavalin A or those of either of these with pokeweed mitogen (itself ineffective) did not potentiate AHH activity over that obtained with phytohemagglutinin or concanavalin A used alone; however, various mitogen combinations were more cytotoxic than individual mitogens. Lipopolysaccharide

B did not affect either cell growth or AHH activity. Using cells cultured under optimal conditions and induced optimally with dibenz(a,h)anthracene, benzo(a)pyrene metabolites were analyzed by high-pressure liquid chromatography. The metabolite profile produced by these cells had several similarities with those produced by mitogen-stimulated, short-term-cultured human lymphocytes derived from fresh blood and by rodent liver microsomes. (54 refs)

- 79-6297 Transplantability of Chemically Induced Skin Tumors in Syngeneic Strains of Mice, Rats and Guinea Pigs. (Eng) Rasanen, O. (Dept. Pathology, Univ. Oulu, SF-90220 Oulu 22, Finland). *Exp Pathol (Jena)* 17(3): 121-127; 1979.

The transplantability of 9,10-dimethyl-1,2-benzanthracene (DMBA)-induced skin tumors in syngeneic strains of mice (NMRI and hr/HR), rats (Sprague-Dawley), and guinea pigs was studied. Although DMBA was a relatively effective inducer of skin tumors, each group of treated animals yielded few tumors suitable for transplantation, since many of the tumors contained necrotic areas and inflammation. Tumors were grafted sc in 100 animals, and in 8 of these a tumor developed within 18 mo. One pleomorphic rat fibrosarcoma grew within 1 mo in all three grafted rats, the resulting tumors being histologically similar to the original. This tumor was injected with a myocardial suspension, which served as a supporting agent. The remaining five tumors grew in the host animals only after 10 mo or more, and it is not certain whether these tumors were really outgrowths of the grafts or spontaneous tumors. (26 refs)

- 79-6298 Immunologic Manipulation of DMBA Tumorigenesis in Hamster Cheek Pouch by DNCB Contact Hypersensitivity. (Eng) Mohammad, A. R. (Dept. Oral Pathology, Coll. Dentistry, Univ. Tennessee Center Health Sciences, Memphis, TN 38163). *J Oral Pathol* 8(3): 147-156; 1979.

The effects of dinitrochlorobenzene (DNCB) on experimental hamster cheek pouch tumors induced by topical dimethylbenzanthracene (DMBA) were studied in male Syrian golden hamsters. The cheek pouches were sensitized with DNCB before the initiation of DMBA tumorigenesis or by direct application to already developed tumors. Among animals treated with DNCB prior to the induction of tumorigenesis, there was an apparent delay in the onset of tumorigenesis and a decreased rate of tumor growth. Direct application of DNCB to established tumors seemed to temporarily arrest tumor growth, but the tumor growth rate later increased to approx that in untreated control hamsters. It is concluded that DNCB contact hypersensitivity may exert some influence on DNCB tumorigenesis. It appears that DNCB sensitization prior to tumor development is generally more effective than application of the allergen after tumor development. (16 refs)

- 79-6299 Apparent Rat Strain-related Sensitivity to Phorbol Promotion of Mammary Carcinogenesis. (Eng) Shellabarger, C. J. (Medical Dept., Brookhaven Natl. Lab., Upton, NY 11973); Holtzman, S.; Stone, J. P. *Cancer Res* 39(9): 3345-3348; 1979.

The promotion of dimethylbenz(a)anthracene (DMBA)-induced mammary carcinogenesis by phorbol (4 mg twice weekly for 10 wk, ip) was studied in female Sprague-Dawley rats. In a previous

experiment. phorbol increased the incidence of mammary adenocarcinomas and lymphatic leukemia in female Wistar rats treated with DMBA. In the present experiment, phorbol given after DMBA (3 mg/100 g body wt by stomach tube) did not augment mammary adenocarcinoma or lymphatic leukemia incidence compared with the effects of DMBA alone. In the Sprague-Dawley rats, phorbol did not promote the incidence of mammary fibroadenomas in DMBA-treated rats, the incidence of mammary adenocarcinomas in procabazine-treated rats, or the incidence of mammary adenocarcinomas or fibroadenomas in x-irradiated rats. DMBA and procabazine, with or without phorbol, tended to induce more mammary tumors in the thoracic than in the abdominal mammary glands. X-irradiation tended to induce mammary neoplasms in approx equal numbers in the thoracic and abdominal glands. The results indicate that there is a strain-related difference in sensitivity between Wistar and Sprague-Dawley rats to phorbol promotion of DMBA carcinogenesis. (13 refs)

- 79-6300 Effects of Dietary Carbohydrate on the Incidence of Mammary Tumors Induced in Rats by 7,12-Dimethylbenz(a)anthracene. (Eng) Hoehn, S. K. (Dept. Biochemistry, Univ. Manitoba, Winnipeg, Manitoba R3E 0W3, Canada); Carroll, K. K. *Nutr Cancer* 1(3): 27-30; 1979.

The effects of purified diets containing sugars or starches on mammary tumor incidence in rats treated with 7,12-dimethylbenz(a)anthracene (DMBA) were compared. Groups of 20 female Sprague-Dawley rats were given a single po dose of 5 mg DMBA at 50 days of age, and 1 wk later they were transferred from a standard laboratory diet to purified diets containing 68% by wt of sugar (dextrose or sucrose) or starch (wheat, rice, or potato starch) and 5% by wt of fat. Sucrose and wheat starch were also fed at a level of 49% in a diet containing 20% fat. Rats fed the sugar diets developed significantly more mammary tumors than those fed the starch diets, at both low and high levels of dietary fat. These results are consistent with epidemiological data showing that age-adjusted breast cancer mortality in humans is positively correlated with sugar intake and negatively correlated with intake of complex carbohydrates. (18 refs)

- 79-6301 Incidence and Growth of Mammary Tumors Induced by 7,12-Dimethylbenz(a)anthracene as Related to the Dietary Content of Fat and Antioxidant. (Eng) King, M. M. (Biomembrane Res. Lab., Oklahoma Medical Res. Foundation, Oklahoma City, OK 73104); Bailey, D. M.; Gibson, D. D.; Pitha, J. V.; McCay, P. B. *J Natl Cancer Inst* 63(3): 657-663; 1979.

To determine whether the ingestion of polyunsaturated fat decreases or antagonizes the inhibitory effect of antioxidants on 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumorigenesis, female Sprague-Dawley rats received one of three diets--high polyunsaturated fat, high saturated fat, and low fat--with and without butylated hydroxytoluene (BHT), beginning at 21 days of age; at 50 days of age, some animals in each group received a single dose of DMBA (10 mg, po) and were followed for development of mammary tumors. The av number of tumors induced per rat as well as tumor size was greatest in the group fed the unsaturated fat diet without BHT. The addition of BHT to the three diets decreased tumor incidence and tumor size in all groups. BHT completely eliminated the increased tumor incidence caused by high levels of saturated fat, but it was much less effective in reducing tumor incidence in animals fed the same level of polyunsaturated fat. The standard Ames mutagenicity assay was modified to determine the

capacity of liver microsomes to form mutagenic compounds from DMBA as a function of the diets fed, without prior treatment of the animals with Aroclor 1254 or phenobarbital. The effects of the various diets, either alone or with BHT, did not appear to be related to the capacity of liver microsomes to produce mutagenic compounds from DMBA, because no differences in the capacity of these microsomes to produce such compounds were observed in any of the dietary groups. (33 refs)

- 79-6302 Histo- and Biochemical Studies on Dehydrogenases in Tumorigenesis in Rat Zymbal Glands Induced with DMBA and DAS. (Eng) Morii, S. (Dept. Pathology, Kansai Medical Univ., Moriguchi, Osaka 570, Japan); Kumazawa, T.; Kusumoto, T.; Harada, H.; Tsubura, A.; Shikata, N. *Acta Histochem Cytochem* 12(4): 361-367; 1979.

The dehydrogenases of Zymbal glands containing tumors induced by 7,12-dimethylbenz(a)anthracene (DMBA: 25 mg/kg, iv, at 51 and 66 days of age) plus 4-dimethylaminostilbene (0.004% of diet starting from age 57 days) were studied in male Wistar SLC rats. Within 11 wk, atypical hyperplasia of acinar cells was detected in the Zymbal glands. Micro- and macroscopically visible squamous cell carcinomas or sebaceous cell carcinomas were observed after 17 wk of treatment; some began to keratinize or became necrotic. Lactic dehydrogenase (LDH) activity was high in the atypical hyperplasias and moderate in the tumor tissues. Glucose-6-phosphate dehydrogenase and succinic dehydrogenase activities decreased during carcinogenesis and were absent from the keratinizing and necrotic areas. During tumorigenesis, malate dehydrogenase (MDH) activity dropped, so that the ratio of LDH/MDH was high in tumor-bearing rats. In general, this ratio began to increase at 8-10 wk and differed significantly ($p < 0.01$) from that in the untreated controls at 11 wk. (10 refs)

- 79-6303 Identification of the Proximate and Ultimate Forms of the Carcinogen 15,16-Dihydro-11-methylcyclopenta[a]phenanthren-17-one. (Eng) Coombs, M. M. (Chemistry Lab., Imperial Cancer Res. Fund, Lincoln's Inn Fields, London, WC2A 3PX, England); Kissonerghis, A. M.; Allen, J. A.; Vose, C. W. *Cancer Res* 39(10): 4160-4165; 1979.

Experiments were carried out to identify the metabolite responsible for the carcinogenicity of 15,16-dihydro-11-methylcyclopenta[a]phenanthren-17-one (I). Enzymatic hydrolysis of calf thymus DNA treated in vitro with I and a microsomal enzyme system followed by column chromatography disclosed two adduct fractions (A and B) eluting after the natural nucleosides. Isolation and hydrolysis of DNA from the skin of male Tyler's Original (TO) mice treated topically with I or from mouse embryo cells exposed to the carcinogen in culture gave mainly adduct B identical to that obtained in vitro. The seven main metabolites formed from I with the microsomal system were isolated by high-pressure liquid chromatography and individually incubated with DNA and the activating system; the DNA was subsequently recovered and analyzed. Adduct B arose from a single metabolite identified as a 3,4-dihydro-*trans*-3,4-dihydroxy derivative of I, on the basis of its UV and mass spectra together with its general chemical behavior. This metabolite was the most mutagenic metabolite in the Ames test and was more active than the carcinogen itself, indicating that it is the proximate form of the carcinogen. The UV spectrum of adduct B resembled that of a 1,2,3,4-tetrahydroderivative of I, but its chromatographic mobility on Sephadex LH-20 was markedly increased by inclusion of borate in the eluant, indicating a *cis*-diol

system. Since the 3,4-diol is *trans*, this suggests further metabolism of the benzo ring. It is therefore proposed that the ultimate carcinogen is a 1,2-dihydro-1,2-epoxy-3,4-dihydro-*trans*-3,4-diol of I. (37 refs)

- 79-6304 Mutagenicity and Tumorigenicity of Phenanthrene and Chrysene Epoxides and Diol Epoxides. (Eng) Wood, A. W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche, Inc., Nutley, NJ 07110); Chang, R. L.; Levin, W.; Ryan, D. E.; Thomas, P. E.; Mah, H. D.; Karle, J. M.; Yagi, H.; Jerina, D. M.; Conney, A. H. *Cancer Res* 39(10): 4069-4077; 1979.

The biological activities of several epoxide and dihydro derivatives of chrysene and phenanthrene were evaluated via mutagenicity studies in *Salmonella typhimurium* strains TA98 and TA100 (ST) and Chinese hamster V79 cells (CHC) and skin tumorigenicity studies in female Charles River CD-1 mice. In ST, the bay-region (\pm)-1 β ,2 α -dihydroxy-3 α ,4 α -epoxy-7,8,9,10-tetrahydrochrysene (I) with the benzylic 1-hydroxy group *trans* to the bay-region epoxide oxygen (I) was four- to sixfold more mutagenic than its diastereomer, (\pm)-1 β ,2 α -dihydroxy-3 β ,4 β -epoxy-1,2,3,4-tetrahydrochrysene (II), and was over 40-fold more mutagenic than the K-region chrysene 5,6-oxide. In CHC, I was fourfold more mutagenic than II, and III was very weakly mutagenic. 3,4-Epoxy-1,2,3,4-tetrahydrochrysene (IV), the most mutagenic chrysene derivative in both systems, was 6- to 18-fold more active than the non-bay-region tetrahydroepoxide, 1,2-epoxy-1,2,3,4-tetrahydrochrysene. 1,2-Dihydrochrysene (V) was metabolized to highly mutagenic products, and both IV and V were as tumorigenic as chrysene on mouse skin. The diastereomeric bay-region diol-epoxides of phenanthrene exhibited dose-dependent mutagenic activity in ST, although they were less active than the corresponding bay-region diol-epoxides of chrysene. (\pm)-1 β ,2 α -Dihydroxy-3 α ,4 α -epoxy-1,2,3,4-tetrahydrophenanthrene (VI) was more mutagenic in ST TA100 and CHC than was its diastereomer, and the two diol-epoxides had low but equivalent activity in ST TA98. In both systems, the bay-region 3,4-epoxy-1,2,3,4-tetrahydrophenanthrene was 7- to 60-fold more mutagenic than was VI and 8- to 17-fold more mutagenic than 1,2-epoxy-1,2,3,4-tetrahydrophenanthrene. Neither phenanthrene nor its three metabolically possible *trans*-dihydrodiols were metabolized to bacterial mutagens by rat liver microsomes, and these compounds showed little or no tumor initiating activity on mouse skin. The bay-region tetrahydro-3,4-epoxide had significant tumorigenic activity on mouse skin. (29 refs)

- 79-6305 Comparative Mutagenicity, Tumor-initiating Activity, Carcinogenicity, and In Vitro Metabolism of Fluorinated 5-Methylchrysenes. (Eng) Hecht, S. S. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Dana Rd., Valhalla, NY 10595); LaVoie, E.; Mazzarese, R.; Hirota, N.; Ohmori, T.; Hoffmann, D. *J Natl Cancer Inst* 63(3): 855-861; 1979.

Seven monofluorinated 5-methylchrysene (5-MeC) derivatives were tested for mutagenicity in *Salmonella typhimurium* TA100 and for tumor-promoting and complete carcinogenic activity on mouse skin; in vitro metabolism in the presence of an activated rat liver homogenate was also investigated. The compounds studied were: 1-fluoro-5-methylchrysene (1-F-5-MeC), 3-fluoro-5-methylchrysene (3-F-5-MeC), 6-fluoro-5-methylchrysene (6-F-5-

MeC), 7-fluoro-5-methylchrysene (7-F-5-MeC), 9-fluoro-5-methylchrysene (9-F-5-MeC), 11-fluoro-5-methylchrysene (11-F-5-MeC), and 12-fluoro-5-methylchrysene (12-F-5-MeC). All seven compounds and 5-MeC were mutagenic toward TA100 in the presence of liver homogenates from F344 rats treated with Aroclor 1254; 7-F-5-MeC was the most mutagenic compound. 1-F-5-MeC and 3-F-5-MeC had significantly less tumor-initiating activity on the skin of Swiss mice than 5-MeC at both doses studied (30 and 100 μ g), whereas 12-F-5-MeC was less tumorigenic than 5-MeC only at 30 μ g. The other derivatives had as much tumor initiating activity as 5-MeC. In the tests of complete carcinogenicity, 1-F-5-MeC, 3-F-5-MeC, and 12-F-5-MeC showed no significant tumorigenicity. The only compound showing tumorigenic activity greater than that of 5-MeC was 6-F-5-MeC. The metabolic study showed that F substitution inhibited the oxidative metabolism at the position of attachment and at neighboring positions. Thus, for 12-F-5-MeC, a major activation pathway was blocked (formation of the 1,2-dihydrodiol); for 6-F-5-MeC, a detoxification pathway was inhibited. (20 refs)

- 79-6306 Multicellular Origin of Fibrosarcomas in Mice Induced by the Chemical Carcinogen 3-Methylcholanthrene. (Eng) Reddy, A. L. (Medical Genetics Section, Medical Service, Veterans Admin. Medical Center, Seattle, WA 98108); Fialkow, P. J. *J Exp Med* 150(4): 878-887; 1979.

The cellular origin of tumors induced by 3-methylcholanthrene (MCA) was investigated in mice with X-chromosome inactivation mosaicism. Male feral mice carrying the electrophoretic variant for the X-linked enzyme phosphoglycerate kinase (PGK type 1A) were bred with females from inbred strains homozygous for the usual *Pgk-1^b*. The F₁ hybrids heterozygous for the wild type and variant PGK genes (*Pgk-1^b/Pgk-1^a*) were given a single dose of MCA (0.2 mg or 2.0 mg sc). Five fibrosarcomas developing at the site of MCA injection were analyzed for the production of type A or type B isoenzyme or a combination of the two. Tumors with a clonal origin in *Pgk-1^b/Pgk-1^a* mice should display either B- or A-type PGK, whereas those with a multicellular origin may exhibit both B and A isoenzymes. Both B and A types of PGK (double-enzyme phenotypes) were found in each of the five tumors. However, single enzyme phenotypes were observed in at least one fragment from a single nodule in two tumors. The neoplasms had gross and histologic features typical of fibrosarcomas with anaplastic spindle-shaped cells and numerous mitoses. Chromosomes in cultured cells were examined at the second passage and almost every cell studied was hyperploid. The occurrence of a double-enzyme phenotype in each MCA-induced tumor strongly suggests a multicellular origin. (16 refs)

- 79-6307 Effect of Testosterone and 6-Hydroxydopamine Treatment on the Metabolism of Catecholamine and 5-Hydroxytryptamine in Methylcholanthrene-induced Prostate Carcinoma of Rats. (Eng) Rastogi, R. B. (Bio-Res. Labs., Ltd., 87 Senneville Road, Senneville, Montreal, Quebec, Canada); Agarwal, R. A.; Jande, S. S.; Singhal, R. L. *Can J Physiol Pharmacol* 57(6): 586-594; 1979.

The precursors tyrosine and tryptophan as well as the synthesizing and deaminating enzymes of catecholamines were identified in methylcholanthrene-induced prostatic carcinomas of Fischer rats. Tyrosine hydroxylase monoamine oxidase, catechol O-methyltransferase, dopamine, 5-hydroxytryptamine, and 5-hydroxyindoleacetic acid seemed to be neoplastic in origin, since

electron microscopic studies failed to reveal the presence of any neuronal elements in this squamous epithelial cell carcinoma. Castration of rats significantly reduced the activity of tyrosine hydroxylase and the levels of tyrosine, dopamine, tryptophan, 5-hydroxytryptamine, and 5-hydroxyindoleacetic acid in prostate tumors. The changes appeared to be androgen-specific, since reinduction of testosterone restored several of these biochemical parameters virtually to control limits. Chemical sympathectomy induced by 6-hydroxydopamine failed to alter monoamine metabolism; however, the prostatic tumors grown in 6-hydroxydopamine-treated rats showed significantly (32%) less necrosis than those grown in normal animals. (33 refs)

- 79-6308 Tumorigenic Activity of 3-Methylcholanthrene Metabolites on Mouse Skin and in Newborn Mice. (Eng) Levin, W. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ 07110); Buening, M. K.; Wood, A. W.; Chang, R. L.; Thakker, D. R.; Jerina, D. M.; Conney, A. H. *Cancer Res* 39(9): 3549-3553; 1979.

3-Methylcholanthrene (MCA) and eight of its metabolites were tested for tumorigenic activity using two tumor models: female CD-1 mouse skin treated with 3-30 nanomoles (nmol) MCA as a single topical application followed 7 days later by twice weekly topical applications of 12-O-tetradecanoylphorbol-13-acetate for 30 wk; and newborn Swiss-Webster BLU:Ha mice given a total of 21 or 49 nmol MCA ip in increasing doses on days 1, 8, and 15 after birth. MCA, 2-hydroxy-MCA, MCA-2-one, and 1,9,10-trihydroxy-9,10-dihydro-MCA were approx equipotent as tumor initiators on mouse skin. 1-Hydroxy-MCA was approx one fourth as active, and MCA-1-one and *trans*-11,12-dihydroxy-11,12-dihydro-MCA showed no significant activity. 1,9,10-Trihydroxy-9,10-dihydro-MCA was the most active compound in inducing pulmonary tumors in newborn mice, MCA and MCA-2-one showing approx one third to one half of this activity, and 2-hydroxy-MCA showing slightly less activity than the latter two. 1-Hydroxy-MCA had marginal activity in this model; and MCA-11,12-oxide, *trans*-11,12-dihydroxy-11,12-dihydro-MCA, and MCA-1-one were inactive. The high tumorigenicity of 1,9,10-trihydroxy-9,10-dihydro-MCA in both models suggests bay-region activation of MCA to an ultimate carcinogen. The data also suggest that other metabolites of MCA may play a role in the carcinogenicity of this compound. (32 refs)

- 79-6309 The Initiation of Tumours on Mouse Skin by Dihydrodiols Derived from 7,12-Dimethylbenz[a]anthracene and 3-Methylcholanthrene. (Eng) Chouroulinkov, I. (Institut de Recherches Scientifiques sur le Cancer, B. P. No. 8, 94800 Villejuif, France); Gentil, A.; Tierney, B.; Grover, P. L.; Sims, P. *Int J Cancer* 24(4): 455-460; 1979.

The *cis*-2a,3-diol and the *trans*-4,5-, *trans*-7,8-, *trans*-9,10- and *trans*-11,12-dihydrodiols of 3-methylcholanthrene and the *trans*-3,4-, *trans*-5,6-, *trans*-8,9- and *trans*-10,11- dihydrodiols of 7,12-dimethylbenz[a]anthracene were compared with the parent hydrocarbons for their abilities to initiate skin tumors in female CD1 mice. Groups of mice received a single topical application (25 µg) of a diol or of a hydrocarbon, and 1 wk later repeated topical applications (1 µg) of 12-O-tetradecanoylphorbol-13-acetate were commenced. The diols capable of being converted into bay-region vicinal diol-epoxides, ie the 9,10-diol of 3-methylcholanthrene and the 3,4-diol of 7,12-dimethylbenz[a]anthracene were active as initiating agents, but no more so than their parent hydrocarbons.

The K-region 5,6-diol of 7,12-dimethylbenz[a]anthracene, which cannot be converted directly into a vicinal diol-epoxide, was also active as a tumor-initiating agent when applied to mouse skin. (29 refs)

- 79-6310 Biochemical and Immunological Characteristics of Tumor Specific Antigens on Chemically Induced Rat Tumors. (Eng) Baldwin, R. W. (Cancer Res. Campaign Labs., Univ. Nottingham, Univ. Park, Nottingham NG7 2RD, England); Price, M. R.; Moore, V. E. In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, R. W., ed. (New York: Elsevier): 590 pp.; 11-24; 1978.

The current status of research into the isolation and characterization of tumor-specific antigens associated with 3-methylcholanthrene (3-MC)-induced sarcomas (MC7 and MC4) and 4-dimethylaminoabobenzene (DAB)-induced hepatomas (D23) in adult WAB/Not rats is reviewed. Antibody specific for D23 and MC7 sarcoma was absorbed only by intact cells and plasma membrane-containing fractions, and immunization of syngeneic rats with extranuclear membrane (ENM) and plasma membrane preparations from sarcoma MC7 indicated that these membrane fractions contained tumor-specific antigen. Solubilization of the membrane-associated antigen required relatively vigorous treatment, including 3 M KCl extraction of tumor homogenates or solubilization of membrane preparations with papain or EDTA. The protein profiles of the fractionated extracts from hepatoma D23 and sarcoma MC4 on ion-exchange chromatograms were markedly similar, as were the regions with which antigenic activities were associated. Gel-filtration chromatography of papain extracts of hepatoma D23 showed that antigenic activity was associated with material eluting with a mol wt of approx 55,000. Specific immunoabsorption techniques applied to the sarcoma MC7 model showed that all antigenic activity resided in a high-mol-wt fraction, and gel electrophoresis of this material showed two major protein bands with approx mol wts of 75,000 and 42,000, respectively. These fractions were immunogenic in syngeneic rats, and the immunoabsorbent-purified fraction from 3 M KCl extracts of sarcoma MC7 elicited a tumor-specific antibody response *in vivo*. However, tumor growth was enhanced rather than suppressed in rats preimmunized with the sarcoma MC7 antigen preparation in Freund's complete adjuvant. (27 refs)

- 79-6311 Effect of Thymosine on Oxidative Phosphorylation in Rat Liver Mitochondria during Chemical Carcinogenesis. (Rus) Grynevych, Iu. A. (Roentgeno-Radiologica and Oncological Inst., Kiev, USSR); Alferov, A. N.; Dziubko, N. Ia.; Chebotarev, V. F. *Ukr Biokhim Zh* 51(3): 255-258; 1979.

The effect of thymosine (TM) on oxidative phosphorylation in liver mitochondria was studied in CBA mice. The animals were inoculated sc with 50 mg/kg 20-methylcholanthrene and sacrificed 10, 30, 50 or 130 days later. Five days prior to sacrifice, rats were immunized with sheep RBC (5×10^9), and 1 day prior to immunization, they received a single ip injection of 5 mg TM. A significant inhibition of oxidative phosphorylation was first recorded on day 50 of carcinogen administration (0.136 unit, compared with 0.162 unit on day 30, 0.183 unit on day 10, and 0.189 unit in controls). Max inhibition of oxidative phosphorylation was observed on day 130 of carcinogenesis (0.110 unit). Administration of TM during the early period of carcinogenesis (up to day 50) enhanced the rate of oxidative phosphorylation (0.198 unit). TM administration on

day 129 of carcinogenesis did not prevent the inhibition of oxidative phosphorylation (0.140 unit). (14 refs)

- 79-6312 Microsomal and Nuclear Metabolism of 3-Methylcholanthrene. (Eng) Tierney, B. (Dept. Biochemistry, Univ. Vermont Sch. Medicine, Burlington, VT 05405); Bresnick, E.; Sims, P.; Grover, P. L. *Biochem Pharmacol* 28(17): 2607-2610; 1979.

Hepatic nuclei and microsomes prepared from rats pretreated with 3-methylcholanthrene 3-MC, 20 mg/kg body wt as well as hepatic nuclei from untreated rats were incubated with generally ^3H -labeled 3-MC (50 μCi plus 0.1 μmole cold 3-MC in acetone) in the presence of an NADPH-generating system. The metabolic products formed by these three systems were analyzed by high pressure liquid chromatography and were found to be comparable both qualitatively and quantitatively. The metabolic formation, from both nuclei and microsomes, of radioactive products corresponding to the *cis*-1,2- and 11,12-diol, the *trans*-4,5-, 9,10-, and 11,12-dihydrodiol, and the 1- and 2-hydroxy and 1- and 2-ketone derivatives of 3-MC was observed when these metabolites were compared on high pressure liquid chromatographs with authentic compounds. Pretreatment of the rats with 3-MC resulted in a marked increase in nuclear metabolism, particularly in the formation of 2-hydroxy-3-methylcholanthrene. These studies further reinforce the importance of the nucleus in the metabolic activation of polycyclic hydrocarbons. (31 refs)

- 79-6313 Induction, Inhibition, and Biological Properties of Aryl Hydrocarbon Hydroxylase in a Stable Human B-Lymphocyte Cell Line, RPMI-1788. (Eng) Freedman, H. J. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., New York, NY 14263); Parker, N. B.; Marinello, A. J.; Gurtoo, H. L.; Minowada, J. *Cancer Res* 39(11): 4612-4619; 1979.

The induction and inhibition of aryl hydrocarbon hydroxylase (AHH) by various chemicals in a stable, human B-lymphocyte cell line (RPMI-1788) are reported, together with the kinetic and biological properties of the enzyme in these cells. Over the dose ranges tested and on molar basis the inducers, in decreasing order of potency, were 2,3,7,8-tetrachlorodibenzo-*p*-dioxin, dibenz(*a,h*)-anthracene, 3-methylcholanthrene, benzo(*a*)pyrene, and 1,2-benzanthracene. Potential inducers that, paradoxically, diminished basal AHH included 7,12-dimethylbenzanthracene, 2,5-diphenyloxazole, and chrysene. Induction under optimal culture conditions ensured maximal activities three- to fourfold above basal AHH. The characteristics of the induced [dibenz(*a,h*)-anthracene] and basal enzymes were identical. Both had similar pH curves (optima at 8.25) and inhibitor specificity (α - and β -naphthoflavones, metyrapone, and 2-diethylaminoethyl-2,2-diphenylvalerate in decreasing potency). Induced and basal enzymes exhibited similar half-lives (41 and 46 hr), apparent activation energies (16.7 and 16.6 kcal/mol), temperature optima (37-38 C and 38-39 C), temperature-dependence of denaturation (range, 42-50 C), and apparent K_m with benzo(*a*)pyrene (1.8 and 0.8 μM). The small difference in the apparent K_m was related to enzyme concentration in the incubation medium rather than to the quality of the enzyme. (56 refs)

- 79-6314 Ovarian Aryl Hydrocarbon Hydroxylase Activity and Primordial Oocyte Toxicity of Polycyclic Aromatic

Hydrocarbons in Mice. (Eng) Mattison, D. R. (Reproductive Toxicology Unit, Pregnancy Res. Branch, Natl. Inst. Child Health and Human Development, NIH, Building 10, Room 13N266, Bethesda, MD 20014); Thorgiersson, S. S. *Cancer Res* 39(9): 3471-3475; 1979.

Mouse ovarian aryl hydrocarbon hydroxylase (AHH) activity was measured in control mice and in DBA/2N (D2) and C57BL/6N (B6) mice treated with 3-methylcholanthrene (3-MC). Basal ovarian AHH activity was similar in both strains (3 picomoles/mg/min). Ovarian AHH was induced two to threefold in B6 mice after 3-MC treatment, but no change was observed in similarly treated D2 mice. Primordial oocytes of both D2 and B6 mice were destroyed by the carcinogenic polycyclic aromatic hydrocarbons (PAH) 3-MC, benzo(*a*)pyrene (BP), and 7,12-dimethylbenz(*a*)anthracene (DMBA), but not by the non-carcinogens pyrene, α -naphthoflavone, and β -naphthoflavone. The rate of primordial oocyte destruction after PAH administration was faster in responsive B6 mice than in nonresponsive D2 mice. After a single ip injection of PAH (80 mg/kg), 50% of the oocytes were destroyed by the following times: DMBA, 1 day for B6, 2 days for D2; 3-MC, 2-3 days for B6, 6 days for D2; BP, 2-3 days for B6, 12 days for D2. Dose-response curves of DMBA, 3-MC, and BP also indicated greater primordial oocyte toxicity in responsive B6 mice than in nonresponsive D2 mice. The threshold dose for oocyte destruction 5 days after PAH injection was: DMBA, <1 mg/kg for B6, <2.5 mg/kg for D2; 3-MC, <5 mg/kg for B6, approx 80 mg/kg for D2; BP, <5 mg/kg for B6, approx 80 mg/kg for D2. In 3-MC-treated D2B6F₁ x D2 backcross mice, PAH-inducible ovarian AHH activity and rapid primordial oocyte toxicity cosegregated with inducible hepatic AHH activity. Primordial oocyte toxicity was blocked by simultaneous treatment with α -naphthoflavone. The relative toxicity of the carcinogens to primordial oocytes in both D2 and B6 mice was DMBA > 3-MC > BP. (21 refs)

- 79-6315 Metabolism of Benzo(*a*)pyrene, *N*-Nitrosodimethylamine, and *N*-Nitrosopyrrolidine and Identification of the Major Carcinogen-DNA Adducts Formed in Cultured Human Esophagus. (Eng) Harris, C. C. (Lab. Experimental Pathology, Building 37, Room 3A07, NCI, Bethesda, MD 20205); Autrup, H.; Stoner, G. D.; Trump, B. F.; Hillman, E.; Schafer, P. W.; Jeffrey, A. M. *Cancer Res* 39(11): 4401-4406; 1979.

Cultured nontumorous esophageal explants from two patients with esophageal carcinoma and six autopsy cases were exposed to [^3H]benzo(*a*)pyrene (BP: 1.5 μM), [^{14}C]N-nitrosodimethylamine (DMN: 100 μM) or [^{14}C]Nitrosopyrrolidine (NPY: 100 μM) for 24 hr. Radioactivity was found bound to both mucosal protein (BP, DMN, and NPY) and DNA (BP and DMN). The major DNA-carcinogen adducts were: (1) with BP, N²-[10 β -7 β , 8 α , 9 α -trihydroxy-7,8,9, 10-tetrahydrobenzo(*a*)pyrenyl] deoxyguanosine; and (2) with DMN, 7-methylguanine and O⁶-methylguanine (ratio of O⁶- to 7-methylguanine was 0.3). The interindividual variations among the samples in binding levels to mucosal DNA were 99-fold for BP and 10-fold for DMN. Both organic solvent-extractable and water-soluble metabolites (sulfate esters, 21%-55%; glucuronide conjugates, 7%-37%; and glutathione conjugates, 24%-66%) were detected in the culture medium. The proximate carcinogenic metabolite of BP, (-)-*trans*-7,8-dihydro-7,8-dihydroxybenzo(*a*)pyrene was detected in the organic solvent-extractable fraction. Analysis of the patterns of both water-soluble and organic solvent-extractable metabolites revealed only minor qualitative differences. These results provide

evidence that the human esophagus has the metabolic capacity to activate the environmental chemical procarcinogens BP and DMN into electrophilic metabolites that bind to DNA and protein. (31 refs)

- 79-6316 The Epoxide Hydratase Inducer Trans-Stilbene Oxide Shifts the Metabolic Epoxidation of Benzo(a)pyrene from the Bay- to the K-Region and Reduces Its Mutagenicity. (Eng) Buckner, M. (Section on Biochemical Pharmacology, Inst. Pharmacology, Univ. Mainz, Obere Zahlbacher Str. 67, D-6500 Mainz, W. Germany); Golan, M.; Schmassmann, H. U.; Glatt, H. R.; Stasiecki, P.; Oesch, F. *Mol Pharmacol* 16(2): 656-666; 1979.

Adult male Sprague-Dawley rats were injected with trans-stilbene oxide (TSO; 2 mmole/kg/day, ip, for three days) and were sacrificed 24 hr later. The following parameters were determined in liver microsomes prepared from TSO-treated rats and controls: monooxygenase and epoxide hydratase activities, and benzo(a)pyrene (BP) metabolite profile and mutagenicity. Epoxide hydratase activity was increased 3-fold and ethoxycoumarin O-deethylase activity 2.5-fold in liver microsomes from TSO-treated rats. (¹⁴C)-BP was incubated with control and with TSO-treated rat liver microsomes and the metabolites separated by high pressure liquid chromatography. The total number of metabolites was not significantly increased after TSO-treatment; but the quantity of metabolites which were oxidized at the benzo ring was greatly decreased, and the K-region metabolites were increased. A much higher percentage of the BP 4,5-oxide was converted to the corresponding dihydrodiol by TSO-induced microsomes compared with controls. Pretreatment of the rats with TSO strongly decreased mutagenicity of BP activated by liver microsomes for *Salmonella typhimurium*. Thus, the two effects of TSO, shift of the site of metabolic oxidation and induction of epoxide hydratase, synergistically provided protection against the mutagenic effects of BP. The changes in BP metabolites occurred without any significant changes in the BP monooxygenase activity, indicating that measurements of aryl hydrocarbon hydroxylase activity do not always correlate with the toxic effects of polycyclic aromatic hydrocarbons. (32 refs)

- 79-6317 Photoelectric Properties and Detection of the Aromatic Carcinogens Benzo(a)pyrene and Dimethylbenzanthracene. (Eng) Houle, W. A. (Dept. Chemistry, Univ. Oregon, Eugene, OR 97403); Brown, H. M.; Griffith, O. H. *Proc Natl Acad Sci USA* 76(9): 4180-4184; 1979.

The absolute photoelectron quantum yield spectra for benzo(a)pyrene (BP) and dimethylbenzanthracene (DMBA) were investigated in the wavelength range 180-230 nanometers (nm). These polycyclic aromatic carcinogens had photoelectron quantum yields of approx 2×10^{-3} electrons per incident photon at 180 nm. The quantum yields fell off quickly and monotonically at wavelengths longer than 210 nm [5.9 electron volts (eV)]. Threshold values for BP and DMBA were 5.25 ± 0.06 eV and 5.17 ± 0.04 eV, respectively. The photoelectron quantum yields of BP and DMBA were several orders of magnitude greater than those of typical components of biological membranes (amino acids, phospholipids, and polysaccharides). Preliminary micrographs of BP and DMBA sublimed onto poly(L-lysine) and onto dimyristoyl phosphatidylcholine demonstrated the high contrast of small crystallites of carcinogens against a background of membrane components. These results and calculations involving relative contrast factors suggest that the distribution of these carcinogens in

biological membranes can be determined by using photoelectron microscopy. (27 refs)

- 79-6318 Genetic Differences in the Metabolic Activation of Benzo(a)pyrene in Mice. Attempts to Correlate Tumorigenesis with Binding of Reactive Intermediates to DNA and with Mutagenesis In Vitro. (Eng) Pelkonen, O. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD 20014); Boobis, A. R.; Levitt, R. C.; Kouri, R. E.; Nebert, D. W. *Pharmacology* 18(6): 281-293; 1979.

An attempt was made to correlate genetic differences in the carcinogenesis index of sc benzo(a)pyrene (BP)-initiated fibrosarcomas with specific genetic differences in any single chromatographic peak, representing a BP metabolite-nucleoside complex, and with specific genetic differences in BP mutagenicity to *Salmonella typhimurium*. The carcinogenesis index in the genetically responsive C3H inbred mouse strain was > fivefold higher and 15-fold higher than in the responsive C57BL/6 and the nonresponsive DBA/2 strains, respectively. Carcinogenesis indices involving F₁ hybrids of these strains indicated that additional genes other than the Ah locus may cause a particular inbred strain to be more resistant, or sensitive, to polycyclic hydrocarbon-initiated tumors than expected solely on the basis of aryl hydrocarbon hydroxylase (AHH) inducibility. The DNA-bound BP metabolite complexes generated by mouse liver or skin microsomes in vitro were resolved into nine chromatographic peaks. Eight peaks, shown previously to be associated with increased hepatic cytochrome P-450 content, were greater with liver microsomes from C3H and C57BL/6 mice and the (C57BL/6)(C3H)F₁, (C3H)(DBA/2)F₁, and (C57BL/6)(DBA/2)F₁ hybrids than from the DBA/2 strain. All nine peaks were greater with skin microsomes in vitro from C3H and C57BL/6 than from DBA/2 mice. BP mutagenicity with *Salmonella* strain TA98 was increased five- to sixfold with liver microsomes from methylcholanthrene-treated C3H and C57BL/6 mice and the three F₁ hybrids, compared with liver microsomes from DBA/2 mice. The data demonstrate a good correlation between genetically determined increases in the in vitro endpoints investigated but not between these two parameters and the carcinogenesis index. (32 refs)

- 79-6319 The Relationship Between Sister Chromatid Exchange, Chromosome Aberration and Gene Mutation Induction by Several Reactive Polycyclic Hydrocarbon Metabolites in Cultured Mammalian Cells. (Eng) Connell, J. R. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks, HP8 4SP, England). *Int J Cancer* 24(4): 485-489; 1979.

The ability of three ultimate metabolites of benzo(a)pyrene as well as of 7-bromomethylbenz(a)anthracene to induce 8-azaguanine mutants, sister-chromatid exchanges, and chromosome aberrations was investigated. 7 β ,8 α -Dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydro-benzo(a)pyrene was an extremely efficient inducer of mutants and sister-chromatid exchanges at 100% survival, whereas its geometrical isomer, 7 β ,8 α -dihydroxy-9 β ,10 β -epoxy-7,8,9,10-tetrahydro-benzo(a)pyrene, and benzo(a)pyrene-4,5-oxide were comparatively weak. The potency of this compound, as both a mutagen and a sister-chromatid exchange inducer, gives further evidence that it may be the important carcinogenic metabolite of benzo(a)pyrene. 7-Bromomethylbenz(a)anthracene was a moderate mutagen and inducer of sister chromatid exchanges.

Comparisons of the relative potencies of these four chemicals as inducers of both mutations and sister chromatid exchanges indicate that these two phenomena are not directly related. The induction of sister chromatid exchanges also appears to be independent of the induction of chromosome aberrations. (23 refs)

- 79-6320 Normal and Benzo(a)pyrene-transformed Fetal Mouse Brain Cells. II. Ultrastructural Study. (Eng) Tripiet, M. F. (Unité de Cancerologie Experimentale, 27 Boulevard Leï'Roure F-13009, Marseille, France); Markovits, P.; Papadopoulos, D.; Toga, M. *Acta Neuropathol (Berl)* 47(3): 205-211; 1979.

Normal and benzo(a)pyrene (BaP: 0.02%)-transformed brain cells from 14-day-old A/J and C3H mouse fetuses were examined ultrastructurally. Control cultures of whole brain cells were of three types: pale, multipolar cells resembling differentiated glial cells, with abundant cytoplasm and elongated processes; rounded, large cells, which were similar to poorly differentiated glial cells; and elongated, apparently nondifferentiated cells that could correspond to spongioblastic cells. In BaP-treated whole brain cultures, some cells appeared similar to mature glial cells and were rich in gliofilaments, which were arranged in dense bundles. Other cells were small and star-shaped, with very long cell processes. Some puncta adherentia-type junctions were observed between plasma membranes. Control fetal cortex cells were oval or rounded with processes and were probably relatively immature neuroglia. The BaP-treated cortex cells were variable in shape and frequently multipolar with long fine processes. No virus particles were observed. (23 refs)

- 79-6321 Normal and Benzo(a)pyrene-transformed Fetal Mouse Brain Cells. I. Tumorigenicity and Immunohistochemical Detection of Glial Fibrillary Acidic Protein. (Eng) Markovits, P. (Section de Biologie, Institut Curie, 26, rue d'Ulm, F-75231 Paris Cedex 05, France); Maunoury, R.; Tripiet, M. F.; Coulomb, B.; Levy, S.; Papadopoulos, D.; Vedrenne, C.; Benda, P. *Acta Neuropathol (Berl)* 47(3): 197-203; 1979.

Morphology, tumorigenicity, and the presence of glial fibrillary acidic protein (GFAP) were studied in normal and benzo(a)pyrene (BaP: 0.02%)-treated brain cells taken from 14-day-old A/Jax or C3H mouse fetuses. Control cultures of cortex remained non-transplantable for up to 14 passages, whereas spontaneous transformation occurred after 11 passages of control whole brain cultures. The latter cultures were tumorigenic in A/Jax mice. After seven to eight passages, malignant transformation was observed in BaP-treated whole brain and cortex cultures. These cells induced tumor formation when injected sc in nude C3H, but not A/Jax, mice with an av latency of 20 (cortex) or 53 (whole brain) days. The induced tumors contained fusiform cells that tended to be arranged in bundles. GFAP was detected in almost all untreated and BaP-treated cultures, although it seemed to be lost from some chemical-treated cortex cultures after 14-16 passages. GFAP was also regularly detected in the tumors induced by transformed cells in nude and A/Jax mice. The data indicate that glia-like cells persist after a long period of maintenance in vitro and transformation. (24 refs)

- 79-6322 Effects of Various In Vitro Inhibitors of Benzo(a)pyrene Metabolism in Isolated Rat Lung

Perfusion. (Eng) Vahakangas, K. (Dept. Pharmacology, Univ. Oulu, Oulu 22, Finland); Nevasaari, K.; Pelkonen, O.; Karki, N. T. *Acta Pharmacol Toxicol (Copenh)* 45(1): 1-8; 1979.

Various in vitro inhibitors of benzo(a)pyrene (BP) metabolism were added with ^3H -BP to fluids used to perfuse isolated rat lung to see whether their effects are dependent on the integrity of the tissue. ^3H -BP and its metabolites were measured by thin-layer chromatography and radiometry in both samples of perfusion medium and homogenates of lung tissue. The total covalent binding to lung tissue was used as a measure of the formation of reactive metabolites. In methylcholanthrene-induced rat lung, BP metabolism was inhibited significantly by α -naphthoflavone (an inhibitor of monooxygenase) and, to a lesser degree, by diethyl maleate (an inhibitor of glutathione), salicylamide (an inhibitor of conjugases), and, surprisingly, by D-saccharo-1,4-lactone (an inhibitor of β -glucuronidase). With trichloropropene oxide, which inhibits epoxide hydratase, the metabolism was either decreased or unchanged. Nicotine had no effect on BP metabolism. Nicotine and diethyl maleate significantly increased and α -naphthoflavone and salicylamide decreased the covalent binding of radioactivity to lung tissue. In most cases, the changes in BP metabolism observed during perfusion were due to the effects of modifiers on the enzyme systems. (15 refs)

- 79-6323 Mutagenic Effects of Benzo(a)pyrene after Metabolic Activation by Hepatic 9000 g Supernatants or Intact Hepatocytes. (Eng) Brouns, R. E. (Inst. Pharmacology and Toxicology, Univ. Nijmegen, Nijmegen, Netherlands); Bos, R. P.; van Gemert, P. J.; Yih-van de Hurk, E. W.; Henderson, P. T. *Mutat Res* 62(1): 19-26; 1979.

The effects of isolated rat hepatocytes and the 9,000-g supernatant from these cells on the mutagenicity of benzo(a)pyrene (BP) toward *Salmonella typhimurium* TA100 were investigated. BP was not mutagenic in the cell-mediated assay unless the hepatocytes were disrupted after they were preincubated with BP or the intracellular glutathione content was reduced. A retention of active metabolites and an effective detoxication may account for the absence of a mutagenic response. (14 refs)

- 79-6324 Theoretical Model Study of the Reactivity of Benzo(a)pyrene Diol Epoxide with the Amino Groups of the Nucleic Acid Bases. (Eng) Lavery, R. (Institut de Biologie Physico-Chimique, Laboratoire de Biochimie Theorique associe au C.N.R.S., 13 rue P. et M. Curie, F-75005 Paris, France); Pullman, B. *Int J Quantum Chem* 16(1): 175-188; 1979.

A quantum-mechanical model study, aided by classical potential calculations, was made of the formation of adducts between the candidate ultimate carcinogen benzo(a)pyrene diol epoxide (BPDE) and the amino groups of guanine, adenine, and cytosine. Considerably less steric hindrance occurs for adducts or intermediates if the metabolized ring of BP adopts a B(I) (boat) or an HC(I) (half-chain) conformation. The quantum-mechanical studies of adducts between the nucleic acid bases and an allyl cation, modeling BPTC (the triol carbonium ion derived from BPDE), suggest that rapid formation of an addition product at the base amino group would occur for guanine, adenine, and cytosine. However, when this intermediate is deprotonated, in an endothermic and slower step, to yield the final adduct, guanine is clearly favored over adenine and cytosine. This result is proposed as at least a partial explanation of the predominance of guanine adducts

when nucleic acids are exposed to BPDE. In a preliminary study of the approach of the BP metabolite toward a five-base pair fragment of B-DNA, it was demonstrated that the minor groove, which contains the guanine amino group, causes more steric hindrance as the BP metabolite approaches than does the major groove, which contains the adenine and cytosine amino groups. (26 refs)

- 79-6325 Benzo(a)pyrene Quinone Metabolism in Tracheal Organ Cultures. (Eng) Mass, M. J. (Dept. Pathology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514); Kaufman, D. G. *Biochem Biophys Res Commun* 89(3): 885-892; 1979.

The hypothesis that benzo(a)pyrene quinones (BP quinones) can be further metabolized by tracheal organ cultures was tested with the use of Syrian golden hamster tracheas. The tracheal organ cultures metabolized a mixture of BP quinones into products that were not extracted with acetone/ethyl acetate and were water-soluble. When the culture medium was extracted of organic-soluble metabolites and the water-soluble metabolites were exposed to β -glucuronidase, BP quinones and an unidentified highly polar metabolite were released. When the results were evaluated quantitatively, it was found that 30% of the water-soluble metabolites were glucuronide conjugates. The remaining 70% of the aqueous soluble radioactivity was not sensitive to β -glucuronidase and was not identified. When BP was used as the substrate in tracheal organ culture, treatment of the aqueous soluble metabolites with β -glucuronidase resulted in the release of some BP quinones. It has previously been assumed that BP quinones are "end-products" of BP metabolism; however, this report demonstrates that BP quinones are subject to further metabolic processes. (17 refs)

- 79-6326 Mutagenicity of Soot and Associated Polycyclic Aromatic Hydrocarbons to *Salmonella typhimurium*. (Eng) Kaden, D. A. (Dept. Nutrition, Food Science, Massachusetts Inst. Technology, Cambridge, MA 02139); Hites, R. A.; Thilly, W. G. *Cancer Res* 39(10): 4152-4159; 1979.

The mutagenic activities of the polycyclic aromatic hydrocarbon (PAH)-containing fractions of several soot samples were measured in *Salmonella typhimurium* strain TM677, using resistance to 8-azaguanine as a genetic marker. Exponentially growing bacterial cultures were exposed to the test agents for 2 hr in the presence of postmitochondrial supernatant, prepared as a 25% liver homogenate of phenobarbital (PB)- or Aroclor (AC)-pretreated male Sprague-Dawley rats. The methylene chloride extracts of nitrogen-containing, sulfur-containing, furnace black, and kerosene soots were 10%-17% as mutagenic as pure benzo(a)pyrene (BP) at concentrations of 20-50 μ g/ml and in the presence of S9 from AC-pretreated rats. Significantly higher concentrations of soot extract or BP were needed to induce significant mutation in the presence of S9 from PB-pretreated rats. The observed mutagenicities of the soot extracts could not be explained by the mutagenicity of BP, and strictly additive mutagenicity was observed when BP was added to nitrogen-containing soot extract. Of 70 PAH components of the soots, 34 induced a significant increase in 8-azaguanine resistance, and 3 of the remaining 36 showed possible low-level mutagenicity. Three PAH, perylene, cyclopenta(c,d)pyrene, and fluoranthene, exhibited greater mutagenicity than BP at equimolar concentrations. The mutagenic

activity of a given PAH was often lower than that of the corresponding aza compound. The mutagenic activity of the PAH fraction of the kerosene soot extract appeared to be due to simple additive contributions of its mutagenic components. (32 refs)

- 79-6327 Anticarcinogenic Effects of 2,3,7,8-Tetrachlorodibenzo-p-dioxin or Benzo(a)pyrene and 7,12-Dimethylbenz(a)anthracene Tumor Initiation and Its Relationship to DNA Binding. (Eng) Cohen, G. M. (Dept. Biochemistry, Univ. Surrey, Guildford, GU2 5XH, Surrey, England); Bracken, W. M.; Iyer, R. P.; Berry, D. L.; Selkirk, J. K.; Slaga, T. J. *Cancer Res* 39(10): 4027-4033; 1979.

The effect of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) pretreatment on the skin carcinogenicity of both benzo(a)pyrene [B(a)P] and dimethylbenz(a)anthracene (DMBA) was investigated in female Sencar mice. The topical administration of 1 μ g 72 hr prior to B(a)P (100 nanomol) or DMBA (10 nanomol) strongly inhibited tumor initiation by both agents. TCDD caused a marked decrease in the in vivo covalent binding of DMBA to DNA and RNA but significantly increased in vivo binding of B(a)P to DNA, with relatively little change in RNA binding. The in vivo binding of B(a)P to DNA in the absence of TCDD pretreatment was accompanied by formation of a major hydrocarbon-deoxyribonucleoside adduct, which cochromatographed with 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene bound to the exocyclic amino group of guanine. The increased in vivo binding to DNA following pretreatment with TCDD did not result in the formation of detectable amounts of this adduct but did result in the formation of other, as yet unidentified, adducts. The authors suggest that the absence of the adduct of 7,8-dihydroxy-9,10-epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene bound to guanine corresponds to the marked tumor-inhibitory properties of TCDD and that formation of this adduct may be a critical step in B(a)P-induced mouse skin carcinogenesis. - 79-6328 Metabolism of Benzo(a)pyrene and the Related Enzyme Activities in Hamster Embryo Cells. (Eng) Hirakawa, T. (Dept. Physiological Chemistry, Faculty Pharmaceutical Sciences, Univ. Tokyo, Hongo, Bunkyo-ku, Tokyo 113, Japan); Nemoto, N.; Yamada, M.; Takayama, S. *Chem Biol Interact* 25(2/3): 189-195; 1979.

The rate of metabolism of benzo(a)pyrene (BP) and changes in related enzyme activities in cultured hamster embryo cells during successive subculture were studied. The activity of aryl hydrocarbon hydroxylase (AHH) was highest when embryo cells were first dispersed in tissue culture flasks and decreased during subsequent passages. On the other hand, uridine diphosphate (UDP)-glucuronyl transferase activity increased gradually during successive subculture. Treatment of the cells with 13 nanomol/ml of benz(a)anthracene (BA) for 24 hr increased the activity of AHH but not that of UDP-glucuronyl transferase. The metabolism of BP was measured in cells of the passages 1, 3 and 7. Metabolism of BP was most efficient in cells in passage 3; and the formation by passage 3 cells of glucuronic acid conjugates of BP, which are among the major metabolites found in the medium, was 3- and 10-fold more than those of cells in passages 1 and 7, respectively. Analysis of BP metabolites extracted from the medium with ethylacetate showed that the main metabolites were 9,10-diol and 7,8-diol. Phenols and quinones were released by treatment of the medium with β -glucuronidase, and their amounts were larger than those of diols at all passages. These results show that in hamster

embryo cells in early passages, BP is metabolized to conjugates of phenols with glucuronic acid. (15 refs)

- 79-6329 **Metabolic Inactivation of Reactive Metabolites.** (Eng) Oesch, F. (Inst. Pharmacology, Section Biochemical Pharmacology, Univ. Mainz, D-6500 Mainz, W. Germany). *Adv Pharmacol Ther* 9: 63-70; 1979.

Benzo(a)pyrene (BP), a compound composed exclusively of aromatic rings, was studied as a model for the mutagenic effects of the aromatic and olefinic moieties of more complex molecules. Chemicals possessing several fused aromatic rings and an angular structure are metabolized to many derivatives. Several of these derivatives are mutagenic but contribute very little to the total mutagenicity of the compound, the two major groups of mutagenically reactive metabolites being monofunctional arene oxides and dihydrodiol epoxides. The monooxygenase forms that are present will in part determine whether BP is predominantly epoxidized at the 4,5-position (monofunctional epoxide) or at the 7,8,9,10-position (dihydrodiol epoxide). A further contributing factor is the relative monooxygenase activity, higher activity favoring the reaction necessary for dihydrodiol epoxide formation. In metabolic situations in which monofunctional arene oxides represent the majority of the mutagenically reactive metabolites, epoxide hydratase efficiently inactivates, whereas if dihydrodiol epoxides predominate, it does not. In the latter situation, another enzyme was found that exerts protective effects complementary to those of epoxide hydratase dihydrodiol dehydrogenase. After the appearance of the primary lesion, differences in repair capacity and other host defense mechanisms will also contribute to differences in toxic manifestations. (25 refs)

- 79-6330 **Carcinogenicity and Polarographic Behaviour of Dibenzo[a,h]pyrene, 4,11-Diazadibenzo[a,h]pyrene and 7,14-Diazadibenzo[a,h]pyrene.** (Eng) Bahna, L. (Cancer Res. Inst., Slovak Acad. Sciences, 880 32 Bratislava, Czechoslovakia); Podany, V.; Benesova, M.; Godal, A.; Dufour, M.; Jacquignon, P.; Vachalkova, A. *Neoplasma* 26(1): 23-28; 1979.

The comparative carcinogenic activities of dibenzo[a,h]pyrene (I), 4,11-diazadibenzo[a,h]pyrene (II), and 7,14-diazadibenzo[a,h]pyrene (III) were studied in random-bred female Wistar rats following sc implantation of paraffin discs containing approx 10 mg of test chemical. Twenty-three local tumors were induced in animals implanted with I, compared with 16 local tumors in those treated with II and no local tumors in those treated with III. Tumor induction time was longer in the animals given II than in those given I. All tumors were sarcomas. The tumorigenicity of I and II was proportional to their electron donation and inversely proportional to their electron acceptance. Judging only by the oxidation potential of III, this compound need not necessarily be wholly inactive as a carcinogen. One reason for its observed inactivity might be that the nitrogen atoms occupying its *meso* region exclude the reaction(s) that would otherwise take place in this region in the parental hydrocarbon (I) during the development of its carcinogenic activity. (11 refs)

- 79-6331 **Large Interindividual Variations in Metabolism of Benzo(a)pyrene by Peripheral Lung Tissue from Lung Cancer Patients.** (Eng) Cohen, G. M. (Dept. Biochemistry, Univ.

Surrey, Guildford GU2 5XH, Surrey, England); Mehta, R.; Meredith-Brown, M. *Int J Cancer* 24(2): 129-133; 1979.

The metabolism of benzo(a)pyrene (BP) in short-term organ cultures of lung tissue from six patients with lung cancer was studied. After a 24-hr incubation of radiolabeled BP with lung tissue, 34.6%-74.8% of the initial radioactivity remained in the medium. Of this radioactivity, 24.7%-55.7% was associated with ethyl acetate-soluble materials and 6.7%-42.4% was associated with water-soluble materials. When the ethyl acetate-soluble radiolabeled material was separated by high-pressure liquid chromatography, metabolites chromatographing with 9,10-dihydro-9,10-dihydroxy-BP or (7/8,9)-trihydroxy-7,8,9,10,10-pentahydro-BP were observed. Two other major peaks corresponded to tetrahydrotetrahydroxy-BP's and more-polar metabolites. There was a 44-fold variation in the amount of BP remaining unmetabolized in the medium; this ranged from 1% in a culture obtained from one patient to 96.2% in a culture obtained from another. The data strongly suggest that there may be little basis for screening humans for variations in lymphocyte aryl hydrocarbon hydroxylase activity as a means of assessing their susceptibility to lung cancer. (23 refs)

- 79-6332 **Metabolism and Macromolecular Binding of the Carcinogen Benzo(a)pyrene and Its Relatively Inert Isomer Benzo(e)pyrene by Hamster Embryo Cells.** (Eng) MacLeod, M. C. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Cohen, G. M.; Selkirk, J. K. *Cancer Res* 39(9): 3463-3470; 1979.

The metabolism and macromolecular binding of benzo(a)pyrene (BP) and its relatively inert structural isomer benzo(e)pyrene (BEP) were studied to determine whether a metabolic basis exists for their different biological activities. BP was metabolized more extensively than BEP to both ethyl acetate-soluble and water-soluble metabolites. The major ethyl acetate-soluble metabolite in the medium after a 24-hr culture with BP was the bay region 9,10-dihydro-9,10-dihydroxybenzo(a)pyrene (9,10-dihydrodiol: 66.7% of the total metabolites). Smaller amounts of 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (7,8-dihydrodiol) were found, but more of this dihydrodiol than the 9,10-dihydrodiol was retained intracellularly, where it could be metabolized to an active diol-epoxide. The major metabolites found in the cytoplasm were 9-hydroxybenzo(a)pyrene and 3-hydroxybenzo(a)pyrene (40.7% and 16.5% of the metabolites, respectively) and the 7,8-dihydrodiol (18.4% of the metabolites). The 9,10-dihydrodiol formed 9.2% of the metabolites. The major ethyl acetate-soluble metabolite formed in the extracellular medium after a 24-hr culture with BEP was the K-region dihydrodiol 4,5-dihydro-4,5-dihydroxybenzo(e)pyrene (69.6% of the organic solvent-soluble metabolites); small amounts of monohydroxybenzo(e)pyrenes (21.9% of the organic solvent-soluble metabolites) were also formed. Most of the latter and significant amounts of the former were metabolized to their respective water-soluble glucuronide conjugates. The metabolic formation of 7,8-dihydrodiol from BP and the apparent lack of formation of 9,10-dihydro-9,10-dihydroxybenzo(e)pyrene from BEP suggests that there is a metabolic basis for the relative biological activities of the parent hydrocarbons. (34 refs)

- 79-6333 **The Formation of Dihydrodiols from Benzo(a)pyrene by Oxidation with an Ascorbic Acid/Ferrous Sulphate/EDTA System.** (Eng) Hewer, A. (Chester Beatty Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, Lon-

don SW3 6JB, England); Ribeiro, O.; Walsh, C.; Grover, P. L.; Sims, P. *Chem Biol Interact* 26(2): 147-154; 1979.

Four dihydrodiols were produced by the oxidation of benzo(a)pyrene in an ascorbic acid/ferrous sulfate/EDTA system. trans-4,5-Dihydro-4,5-dihydroxybenzo(a)pyrene, trans-7,8-dihydro-7,8-dihydroxybenzo(a)pyrene, and trans-9,10-dihydro-9,10-dihydroxybenzo(a)pyrene were identified by their UV spectra and by direct comparisons of their chromatographic properties, using high-pressure liquid chromatography, with those of the authentic compounds. The fourth compound appeared to be trans-11,12-dihydro-11,12-dihydroxybenzo(a)pyrene, since its UV spectrum was identical to that of the cis-dihydrodiol. Time-course experiments showed that the max amounts of products were obtained after 8 hr of oxidation. A reexamination of the dihydrodiols formed from benzo(a)pyrene by rat liver microsomal fractions failed to show the formation of the trans-11,12-dihydrodiol. (16 refs)

- 79-6334 Differences in Mutagenicity and Cytotoxicity of (+) and (-)-Benzo[a]pyrene 4,5-Oxide: A Synergistic Interaction of Enantiomers. (Eng) Chang, R. L. (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche Inc., Nutley, NJ 07110); Wood, A. W.; Levin, W.; Mah, H. D.; Thakker, D. R.; Jerina, D. M.; Conney, A. H. *Proc Natl Acad Sci USA* 76(9): 4280-4284; 1979.

The (+) and (-) enantiomers of benzo(a)pyrene (BP)-4,5-dioxide were compared with respect to their mutagenicity for four strains of *Salmonella typhimurium* and their mutagenicity and cytotoxicity for Chinese hamster V79 cells. A linear dose-response relationship was seen in all four bacterial strains. The (-) enantiomer was 1.5- to 5.5-fold more mutagenic than the (+) enantiomer for *S. typhimurium* strains TA98, TA100, TA1537, and TA1538 and for V79 cells. The (-) enantiomer was also more cytotoxic for V79 cells than was the (+) enantiomer. When mixtures of the enantiomers were studied using V79 cells, synergistic cytotoxic and mutagenic effects were observed. The greatest effects were observed using a 3:1 mixture of the (-) and (+) enantiomers. (28 refs)

- 79-6335 DNA-Benzo(a)pyrene Adducts Formed in a *Salmonella typhimurium* Mutagenesis Assay System. (Eng) Santella, R. M. (Div. Environmental Science, Cancer Center/Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, New York, NY); Grunberger, D.; Weinstein, I. B. *Mutat Res* 61(2): 181-189; 1979.

The DNA adducts formed in *Salmonella typhimurium* when the bacteria were incubated with radioactive benzo(a)pyrene (BP) and liver microsomal enzymes from different sources were studied. When enzyme preparations from Aroclor 1254- or 3-methylcholanthrene-induced C57BL/6N (B6) mice were used to mediate activation, the predominant product was an adduct between the 10 position of 7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydro-BP and the N-2 position of deoxyguanosine. Similar results were obtained with human liver and with Aroclor-induced rat liver enzyme preparations. This adduct was also the major DNA product found previously when human tissues or certain rodent cells were incubated with BP. When activation of BP was mediated by a phenobarbital-induced B6 mouse liver enzyme preparation, the extent of binding was quite low and the profile of DNA adducts in *S. typhimurium* DNA was quite different. Thus, under appropriate conditions, the activation and DNA binding of

BP in the microsome-mediated *S. typhimurium* assay generally resembles that seen in intact mammalian cells. Caution must be exercised, however, in the choice of microsome-activation systems. (21 refs)

- 79-6336 A Quantitative Comparison of the Mutagenicity of Carcinogenic Polycyclic Hydrocarbon Derivatives in Cultured Mammalian Cells. (Eng) Newbold, R. F. (Chemical Carcinogenesis Div., Inst. Cancer Res., Pollards Wood Res. Station, Nightingales Lane, Chalfont St. Giles, Bucks HP8 4SP, England); Brookes, P.; Harvey, R. G. *Int J Cancer* 24(2): 203-209; 1979.

A series of reactive hydrocarbon derivatives was tested for cytotoxicity and ability to induce 8-azaguanine-resistant mutants in Chinese hamster V79/4-K₁ cells. The anti- and syn-benzo(a)pyrene-7,8-dihydrodiol-9,10-oxides (I and II, respectively), 1-oxiranylnaphthalene, and 7-bromomethylbenzo(a)anthracene (IV) were more effective mutagens than the other compounds tested. In V79 cells cocultured with a feeder layer of hydrocarbon-metabolized BHK 21/13 fibroblasts, anti-BP-diol epoxide (I) was the most potent mutagen (mutation frequency plotted as a function of percentage survival), particularly in its ability to induce large numbers of mutants at minimally lethal doses. II, IV, and BP-4,5-oxide were indistinguishable with respect to their mutagenicities. At equal extents of DNA reaction, IV, I, and syn-BP-diol epoxide were essentially equally cytotoxic, but I was four- to eightfold more mutagenic than the others at equal levels of binding. Thus, I had a higher "absolute mutagenic efficiency" (mutagenicity per unit extent of DNA reaction). (40 refs)

- 79-6337 Mutagenic Cholesterol Preparations. (Eng) Smith, L. L. (Div. Biochemistry, Dept. Human Biological Chemistry and Genetics, Univ. Texas Medical Branch, Galveston, TX 77550); Smart, V. B.; Ansari, G. A. *Mutat Res* 68(1): 23-30; 1979.

Naturally air-aged commercial samples of cholesterol stored for different lengths of time were tested for mutagenicity toward five *Salmonella typhimurium* strains. Dose-response mutagenicities were obtained without metabolic activation for five of six naturally air-aged samples tested at 1.2-12 mg/plate with strains TA1537, TA1538, and TA98 (frame-shift mutagens); they were not mutagenic with strains TA1535 and TA100 (base-pair mutagens). Pure crystalline cholesterol free from detectable autooxidation products was nonmutagenic in all five strains. Similar dose-response relationships were obtained with strains TA1537, TA1538, and TA98 over the sample range 1.2-12 mg/plate for pure non-mutagenic cholesterol after it had been heated to 70 C in air or γ -irradiated in air. Several individual cholesterol autooxidation products were tested with these same strains and were nonmutagenic at levels as high as 6 mg/plate. These results show that unidentified autooxidation products of cholesterol are frameshift mutagens in *Salmonella* and demonstrate that the sterols and unsaturated lipids are classes of important biological compounds from which mutagens may derive. (54 refs)

- 79-6338 Biosynthesis of Cholesteryl 14-Methylhexadecanoate in the Liver of Rats Bearing Transplantable Tumors and During Chemical Carcinogenesis. (Eng) Kvcála, J. (Oncological Inst., 180 00 Prague 8, Czechoslovakia); Hradec, J. *Neoplasma* 26(1): 29-38; 1979.

The biosynthesis of cholesteryl 14-methylhexadecanoate, cholesteryl palmitate, and cholesteryl stearate was studied in the liver of female Wistar rats bearing Walker 256 carcinomas and Zajdela hepatomas and during chemical carcinogenesis induced by benzo(a)pyrene. The production of all three esters was enhanced up to ninefold in liver homogenates during days 10-16 after transplantation of the Walker tumor. Only the enzyme system esterifying cholesterol in the cytosol at pH 6.5 was stimulated; the activity of similar enzymes in mitochondria, microsomes, and cytosol at an acid pH was not affected. The activity of the cytosol enzyme esterifying cholesterol at pH 6.5 was also enhanced during active growth of the Zajdela hepatoma and during chemical carcinogenesis characterized by the appearance of palpable sc tumors. The enhanced activity of the cholesterol-esterifying enzymes in the liver coincided with the periods of elevated cholesteryl 14-methylhexadecanoate levels in the liver and blood plasma as described earlier. An increased demand of the tumor-bearing host for this cholesteryl ester, which is utilized as a cofactor for enhanced protein synthesis, is met by its stimulated production in the liver tissue. - 79-6339 The Relationship Between Zinc and Vitamin A in Cancer Patients. (Eng) Capel, I. D. (Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey RH8 0TL, England); Williams, D. C. *IRCS Med Sci [Cancer]* 7(7): 361; 1979.

Serum zinc level and its possible correlation with vitamin A status were studied in 245 cancer patients and 22 age-matched controls. Serum levels of both zinc and vitamin A in the patients and controls were within normal limits, but the zinc levels were higher ($p < 0.05$) and the vitamin A levels lower ($p < 0.05$) in the patients than in the controls. Both vitamin A and zinc levels were significantly higher in the 77 breast cancer patients than in the other cancer patients. Excluding the values for the female breast cancer patients, there were no significant sex differences among the cancer patients. The data suggest that serum vitamin A level may be dependent on zinc when limited amounts of this metal are available. (9 refs)

- 79-6340 The Metabolic Activation of *trans*-4-Dimethylaminostilbene After Oral Administration of Doses Ranging from 0.025 to 250 $\mu\text{mol/kg}$. (Eng) Neumann, H. G. (Inst. Pharmacology and Toxicology, Univ. Wurzburg, Wurzburg, W. Germany); Gaugler, B. J.; Taupp, W. In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 177-190; 1978.

^3H -*trans*-4-dimethylaminostilbene (*trans*-DAS) was given po to female Wistar rats at one of five doses (0.025, 0.25, 2.5, 25, or 250 $\mu\text{moles/kg}$). The animals were sacrificed 5 hr later; and the total radioactivity bound to liver proteins and nucleic acids, plasma proteins, and Hb was determined. Total radioactivity increased linearly with dose in liver and blood at the three lower doses; but at the higher doses, the tissue radioactivity rose less proportionately. Three soluble liver protein fractions, liver DNA and RNA, and plasma proteins all demonstrated a biphasic correlation between metabolite binding and dose. At the three lower doses, the radioactivity increased in proportion to dose but was less than directly proportional after administration of the higher doses. These results demonstrate that *trans*-DAS metabolites, including those

that can react with cellular macromolecules, are distributed within the liver cell and into the circulation in a manner remarkably independent of the dose. It was concluded that the relative rates of the reactions encountered in the metabolism of this compound remain constant over a wide range of doses; the relative rates of the metabolic reactions may not have changed in the higher dose range, but rather the rate of absorption may have decreased. Since binding to such different macromolecules as proteins, RNA, and DNA depended on the dose in the same way, total binding may be a relative measure of the biochemical lesion induced by an individual dose of *trans*-DAS. - 79-6341 Metabolites of Diethylstilboestrol Induce Sister Chromatid Exchange in Human Cultured Fibroblasts. (Eng) Rudiger, H. W. (Universitäts-Krankenhaus, Eppendorf, Martinistr. 52, D-2000 Hamburg 20, W. Germany); Haenisch, F.; Metzler, M.; Oesch, F.; Glatt, H. R. *Nature* 281(5730): 392-394; 1979.

The induction of sister chromatid exchange (SCE) in cultured human fibroblasts, by diethylstilbestrol and two of its metabolites, diethylstilbestrol- α,β -oxide (DES- α,β -oxide) and β -dienestrol was investigated. In diploid fibroblast cultures from five different donors, lower concentrations of DES were sufficient to cause SCE than of the positive control, benzo(a)pyrene (BP). An increase in SCE was observed at even lower concentrations of DES- α,β -oxide and β -dienestrol than of DES. Concentrations required for half maximal induction of SCE by DES, DES- α,β -oxide, β -dienestrol, and BP were 133 nM, 40 nM, 5 nM, and 2,100 nM, respectively. The induction of SCE by DES was completely inhibited by α -naphthoflavone, a monooxygenase inhibitor, and was markedly inhibited by β -dienestrol. The SCE-induction obtained with DES- α,β -oxide was decreased by 35% in the presence of α -naphthoflavone. These results indicate that DES and also β -dienestrol require metabolic activation by monooxygenase for the induction of SCE. Neither DES nor its two metabolites induced mutations in *Salmonella typhimurium* strains TA100, TA1535, TA1537, or TA98. (21 refs)

- 79-6342 Evaluation of the Transplacental Toxicity of Diethylstilbestrol with the Scanning Electron Microscope. (Eng) Lamb, J. C. (Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709); Newbold, R. R.; McLachlan, J. A. *J Toxicol Environ Health* 5(4): 599-603; 1979.

Exposure in utero to the synthetic estrogen diethylstilbestrol (DES) is associated with reproductive tract lesions in male and female CD-1 mice. The scanning electron microscope was used to evaluate the luminal surface of the vagina, cervix, and uterus of these mice following prenatal exposure to DES (10 $\mu\text{g/kg}$ sc on gestation days 9-16). Observed abnormalities included urethral openings in the cervicovaginal area, squamous metaplasia of the uterus, glandular elements in the vagina, and abnormal cell-surface features in the vaginal epithelium. - 79-6343 Risks of Chemical Pollution of Drinking Water. I. Study of Long-Term Toxicity of Chloroform-extractable Organic Micropollutants from Drinking Water Used for Human Consumption in Rats and Mice. (Fre) Truhaut, R. (Centre de Recherches Toxicologiques, Faculte des Sciences, Phar-

maceutiques et Biologiques de Paris-Luxembourg, 4, avenue de l'Observatoire, 75006 Paris, France); Gak, J. C.; Graillot, C. *Water Res* 13(8): 689-697; 1979.

The effects of organic pollutants extracted with chloroform at pH 7 from drinking water in Paris were tested in 50 rats and 50 mice of both sexes. The animals received a diet containing 100 or 200 times more organic pollutant than would be consumed by a 60-kg human drinking 3 liters of water daily; the diet was administered from the time of weaning until death. The incidence of malignant tumors was 0% in control male rats, 33.3% in males treated with the 100x dose, and 50% in males treated with the 200x dose. In female rats, the incidence of malignant tumors was 4.5% in the controls, 40% in the 100x dose group, and 57.1% in the 200x dose group, ie, there was a dose-response relationship in both male and female rats. In the mice, the incidence of malignant tumors was 4.9% in male controls and 11.1% in males treated with 100x and 200x doses. Malignant tumors were found in 14.3% of control female mice, in 43.8% of females given the 100x dose, and in 45% of those given the 200x dose; thus, significant increases in tumor incidence were found in female mice only, but there was no dose-response relationship in either sex. The tumors were mainly mammary and ovarian adenocarcinomas in female rats, thyroid tumors in male rats, and lymphosarcomas in both sexes; all three tumors were also found in mice. (18 refs)

- 79-6344 Risks of Chemical Pollution of Drinking Water. II. Comparative Studies on the Long-Term Toxicity of Organic Micropollutants Extracted from Waters Used in Drinking Water Preparation. (Fre) Graillot, C. (Centre de Recherches Toxicologiques, Faculte des Sciences Pharmaceutiques et Biologiques de Paris-Luxembourg, 4, avenue de l'Observatoire, 75006 Paris, France); Gak, J. C.; Lancret, C.; Truhaut, R. *Water Res* 13(8): 699-710; 1979.

Fifty rats and 60 mice (half males and half females) received, from the time of weaning, a diet containing chloroform-extracted organic pollutants from raw river water used for drinking water preparation. The extracts were divided into fractions with low (f) and high (F) cytotoxicity, established by preliminary cytotoxicity tests. Each fraction was tested in doses of 25 mg/kg (f1 and F1) and 50 mg/kg (f2 and F2). In male mice, the incidence of malignant tumors was 0% in the controls, 5.9% in group f1, 5.3% in f2, 0% in F1, and 10.5% in F2. In female mice, the tumor incidence was 8% in the controls, 59.3% in f1, 52.4% in f2, 59.3% in F1, and 59.1% in F2. In male rats, the tumor incidence was 9.1% in the controls, 17.7% in f1, 47.4% in f2, 11.8% in F1, and 36.8% in F2. In female rats, the tumor frequency was 4.8% in the controls, 9.5% in f1, 36.4% in f2, 16.7% in F1, and 42.9% in F2. Although there was a dose-response relationship, there was no correlation between the degree of cytotoxicity and the incidence of malignant tumors. The tumors were mainly adenocarcinomas of the mammary gland, lymphosarcomas, and other sarcomas. (9 refs)

- 79-6345 Effects of Progesterone on Mammary Carcinogenesis by DMBA Applied Directly to Rat Mammas. (Eng) Jabara, A. G. (Dept. Veterinary Paraclinical Sciences, Univ. Melbourne, Parkville, Victoria 3052, Australia); Marks, G. N.; Summers, J. E.; Anderson, P. S. *Br J Cancer* 40(2): 268-273; 1979.

The effects and site(s) of action of progesterone (3 mg/day, 3x/wk, sc) on 7,12-dimethylbenz(a)anthracene (DMBA)-induced

mammary carcinogenesis were studied in the female Sprague-Dawley rat. The surgically exposed right fourth mammary gland was dusted with 2 mg of powder containing a DMBA-cholesterol mixture (1:1). Tumors developed only in DMBA-treated mammary glands. In animals treated with progesterone for 135 or 197 days, 29/51 that developed mammary carcinomas also developed nonmammary neoplasms of the skin or body wall at the site of DMBA dusting. The mammary tumor incidence and av tumor latent period was similar in rats treated with DMBA alone and those treated with progesterone for 18 days prior to DMBA treatment. However, in rats treated with progesterone starting 2 days before and continuing for 135 days after DMBA treatment, the tumor incidence was greater and the latent period shorter than in the DMBA-only group ($P < 0.05$). In general, progesterone treatment before DMBA treatment had no influence on mammary tumorigenesis, whereas progesterone treatment after DMBA treatment stimulated continuous tumor growth ($P < 0.01$). Tumor size was also greater in rats treated with progesterone after DMBA; at autopsy, 53% of the neoplasms in these animals had obtained an av size of ≥ 2 cm, compared with only 89% and 25% in groups treated with progesterone before DMBA administration. All mammary carcinomas were adenocarcinomas, and progesterone did not influence their macro- or microscopic appearance. Most nonmammary neoplasms were fibrosarcomas. The data suggest that progesterone may exert its inhibitory effect on carcinogenesis via action at a site outside the breast, perhaps the liver. However, it is likely that the hormone acts directly on the mammary tissue to enhance tumorigenesis. (18 refs)

- 79-6346 Steroid Binding Proteins of Mammary Tissues and Their Clinical Significance in Breast Cancer. (Eng) Wittliff, J. L. (Dept. Biochemistry, Univ. Louisville Sch. Medicine, Louisville, KY 40232); Lewko, W. M.; Park, D. C.; Kute, T. E.; Baker, D. T.; Kane, L. N. *Prog Cancer Res Ther* 10: 325-359; 1978.

Data regarding the kinetic and molecular characteristics of steroid binding proteins in normal mammary gland and in several hormonally responsive rat mammary tumors and human breast tumors are summarized. In general, the kinetic and molecular properties of estrogen receptors (EGR's), glucocorticoid R's, and progesterin R's in normal rat mammary tissues and tumors were similar. These R's were studied in hormonally responsive mammary tumors induced in female rats by N-nitrosomethylurea and 7,12-dimethylbenz(a)anthracene, those induced in female C3H mice by EG's, and the hormonally responsive R3230AC mammary tumor, which is transplantable in female Fischer 344 rats. Studies of the influence of EGR complexes on RNA polymerase activity suggest that the activation of mammary gland estradiol-R complexes is a prerequisite for its nuclear translocation and subsequent stimulation of nuclear synthetic activity. The distributions of both the EG and progesterone R's in a breast tumor may be predictive indices of a response to hormone manipulation. In general, the specific EG binding capacities of mastectomy specimens of patients with no nodal involvement were similar to those of patients with nodal involvement. The 8S EGR of lactating mammary gland was composed of at least two components, each with different ionic properties. The 8S EGR of human breast tumors separated into a variable number of components with different ionic properties, and the 4S EGR of these tumors separated into at least two components with different ionic properties. The data suggest that EGR's of human breast cancers exhibit molecular heterogeneity and that the molecular properties of EGR's in human breast tumor biopsies may be related to the clinical responsiveness of patients treated by hormonal manipulations. 79-6347 Progesterone and Estrogen Receptors in Japanese Breast Cancer. (Eng) Matsumoto, K. (Inst. Cancer Res., Osaka Univ. Medical Sch., Kita-ku, Osaka 530, Japan); Ochi, H.; Nomura, Y.; Takatani, O.; Izuo, M.; Okamoto, R.; Sugano, H. *Prog Cancer Res Ther* 10: 43-58; 1978.

The presence of estrogen receptors (ER) and progesterone receptors (PR) among 1,060 Japanese breast cancer patients was studied. Measurable numbers of ER were found in 615/1,060 (58%) of the cancers studied. This rate is within the lowest range of rates reported in Western countries. The rates of ER-positive tumors among pre- and postmenopausal Japanese women were similar to those among Western women. Forty-one of 82 ER-positive breast cancers responded to endocrine therapy, as compared with only 5/57 ER-negative cancers. The response rates were similar to those in Western patients. Measurable numbers of PR were found in 171/474 Japanese breast cancers. This rate is somewhat lower than that observed among Western patients. PR was found in 51% of ER-positive cancers and 13% of ER-negative cancers. The frequency of PR increased with ER content. Positive responses to endocrine therapy were obtained with 12/20 tumors positive for ER and PR, 9/25 tumors positive for ER but not PR, 2/20 tumors negative for ER and PR, and 0/1 positive for PR but not ER. The data indicate that assays of ER and/or PR are useful for predicting the response to endocrine therapy for breast cancer among patients of any race. (35 refs)

79-6348 Prevention and Treatment of Endometrial Disease in Climacteric Women Receiving Oestrogen Therapy. (Eng) Thom, M. H. (King's Coll. Hosp., London, England); White, P. J.; Williams, R. M.; Sturdee, D. W.; Paterson, M. E.; Wade-Evans, T.; Studd, J. W. *Lancet* 2(8140): 455-457; 1979.

The treatment regimens in 74 women with endometrial disease among 850 climacteric women receiving estrogen or estrogen-progestagen therapy were studied. Cystic hyperplasia was associated with unopposed estrogen therapy without progestagen. Two 21-day courses of treatment with norethisterone (5 mg/day) caused reversion to normal in all 57 cases of cystic hyperplasia and in 6/8 cases of adenomatous hyperplasia, but had no such effect in two cases of atypical hyperplasia. Four cases of endometrial carcinoma demonstrated the problems associated with inappropriate and unsupervised unopposed estrogen therapy and the difficulty in distinguishing between severe hyperplasia and malignancy. Cyclical low-dose estrogen therapy combined with 7-13 days of progestagen therapy did not appear to increase the risk of endometrial hyperplasia or carcinoma. (19 refs)

79-6349 Hormone Receptors and Histopathology in Japanese Breast Cancer. (Eng) Sugano, H. (Dept. Pathology, Cancer Inst., Japanese Foundation Cancer Res., Toshima-ku, Tokyo 170, Japan); Sakamoto, G.; Sakamoto, A.; Nomura, Y.; Takatani, O.; Matsumoto, K. *Prog Cancer Res Ther* 10: 59-70; 1978.

Relationships between histopathological types of breast cancer and estrogen, progesterone, and androgen receptors (ER, PR, and AR) were studied among Japanese women, and the results were compared with those obtained among American women. Except for a low incidence of lobular carcinoma among Japanese women, the distributions of histological types of breast cancer among Japanese and American women did not differ greatly. Of the Japanese cancers analyzed, 188/324 were positive for ER, 59/179 were

positive for PR, and 21/80 were positive for AR. ER were present in a high percentage of lobular carcinomas, and the frequencies of ER, PR, and AR were low in cancers showing lymphocyte infiltration. These tendencies, which were not statistically significant, were similar to those observed in American cancers. A significantly low frequency of PR and ER/PR, and a nonsignificantly low frequency of ER were observed in medullary tubular carcinomas. There was no remarkable relationship between histological factors of prognostic significance and the presence of hormone receptors, but the ER distribution tended to parallel that of PR. The hypothesis that local lymphocyte infiltration is related to a good prognosis for breast cancer among the Japanese was not supported. (33 refs)

79-6350 Effect of Contraceptive Steroids on Mammary Gland of Beagle Dog and Its Relevance to Human Carcinogenicity. (Eng) El Etreby, M. F. (Dept. Experimental Toxicology and Endocrine Pharmacology, Res. Labs. Schering AG, Berlin Bergkamen, 1000 Berlin 65, W. Germany); Graf, K. J. *Pharmacol Ther* 5(1-3): 369-402; 1979.

The effects of various progestagens, estrogens, and progestagen-estrogen combinations on the dog mammary gland were studied, and the results were discussed together with those of previous systemic tolerance tests and carcinogenicity studies. Mammary gland hyperplasia occurred in a dose-dependent fashion after treatment with progesterone, progestagens, estrogens, and hormone combinations. These hyperplastic processes occurred from the fourth wk of treatment onward and could be reversed in spite of continued treatment. Estrogens seemed to induce predominantly proliferation and ectasia of the ductal system of the canine mammary glands, with no signs of alveolar development. Progestagens mainly caused dose-dependent lobulo-alveolar growth, including epithelial and myoepithelial proliferation. This effect was evident for certain progestagens even in doses below or nearly at the minimal human ovulation-suppressing dose. In several long-term studies with progesterone and certain progestagens and progestagen-estrogen combinations, an increased number of mammary nodules was observed from the second or third yr onward, even with doses as low as the human ovulation-suppressing dose. 0 Ethinyl estradiol, mestranol, and some 19-nortestosterone derivatives and their combinations did not significantly influence the occurrence of mammary nodules. The nodules could be reversed when treatment was continued or stopped. Most of the nodules were regarded as lobular hyperplasias or benign tumors, but some malignant tumors were also diagnosed. It is unlikely that steroid-related canine mammary tumors are indicative of a potential hazard to humans. (92 refs)

79-6351 Hormonally Induced Tumors of the Reproductive System of Parabiosed Male Rats. (Eng) Brown, C. E. (Cancer Res. Inst., New England Deaconess Hosp., 185 Pilgrim Road, Boston, MA 02215); Warren, S.; Chute, R. N.; Ryan, K. J.; Todd, R. B. *Cancer Res* 39(10): 3971-3976; 1979.

The appearance of neoplasms in the target organs of male rats parabiosed to castrated males or to oophorectomized females was studied. Among 20 parabiosed pairs completing the long-term experiment (387-750 days postcastration), 11 interstitial cell tumors of the testis and 4 adenocarcinomas of the prostate developed in the target partners. Eight of these tumors occurred in pairs in which each partner was unilaterally nephrectomized. Serum luteinizing hormone, follicle-stimulating hormone, testosterone, and androstenedione levels were elevated in the parabiosed pairs. The nonneoplastic testes of target partners showed slight increases in

weight over controls, and the prostates and seminal vesicles of the target partners were moderately enlarged and filled with thick, milky fluid. Microscopic foci of adenocarcinoma were found in the dorsolateral lobes of the prostates of four unilaterally nephrectomized target males. Many of the prostates of target partners showed apparent generalized hyperplasia. The data suggest that a correlation exists between internally generated gonadotropins and the development of interstitial cell tumors of the testis, and that there is a correlation between serum androgen levels and the development of prostate adenocarcinomas in rats. (18 refs)

- 79-6352 Contraceptive Hormones: The Problem of the Induction of Mammary Gland Nodules in Beagle Dogs Given Progestogens. (Eng) Graf, K. J. (Free Univ., Berlin, W. Germany); El Etreby, M. F.; Neumann, F. In: *Proceedings of the 1st International Congress on Toxicology: Toxicology as a Predictive Science, held in Toronto, Canada, 30 March- 2 April 1977*. Plaa, G. L.; Duncan, W. A., eds. (New York: Academic Press, Inc.): 670 pp.; 225-243; 1978.

The role of chemical configuration, of progestogenic activity, and of the interference of progestogens with prolactin and/or growth hormone secretion is discussed in relation to the tumorigenicity of some progestogens in the canine mammary gland. Hydroxyprogesterone derivatives and 19-nor-testosterone derivatives as well as estrogens and estrogen-progestogen combinations induce proliferative mammary lesions in the dog. Previous studies were extended through the use of a progestogen test model using ovariectomized female beagles to estimate the transforming potency of progestogens at the canine endometrium. It was found that the 17 α -hydroxy-progesterone derivatives were much more powerful than the 19-nor-testosterone derivatives. In contrast, the 19-nor-testosterone derivatives are more active with respect to endometrial transformation in women. In the dog, progestogens and possibly growth hormone seem to be the main factors affecting mammary gland growth; however, in other species, the role of

estrogens remains to be clarified, and prolactin is assumed to be primarily responsible for functional secretory activity only. In a study of the influence of synthetic progestogens (cyproterone acetate, 100 mg/kg) on prolactin secretion, no significant differences were detected between the pre- and post-treatment prolactin concentrations. Histological examination of the mammary gland tissue, however, revealed proliferation of the duct system with signs of hyperplasia. It is concluded that the induction of mammary gland nodules in dogs by certain progestogens must be considered a species-specific effect. (25 refs)

PHYSICAL CARCINOGENESIS

- 79-6353 The Effects of β -Radiation on Sister-Chromatid Exchanges in Cultured Human Lymphocytes. (Eng) Crossen, P. E. (Cancer Society New Zealand, Cytogenetics Unit, Christchurch Hosp., Christchurch, New Zealand); Morgan, W. F. *Mutat Res* 62(1): 125-129; 1979.

The 5-bromodeoxyuridine/Giemsa technique was used to investigate the incidence of sister-chromatid exchanges (SCE's) due to β -radiation in cultured human lymphocytes. Cultures treated continuously with 0.001 or 0.01 μ Ci of [3 H]uridine for 48 hr showed no increase in either chromosome abnormalities or SCE's. Continuous treatment with 0.1 μ Ci resulted in a significant increase in chromosome aberrations but no increase in SCE's, whereas treatment with 0.2 μ Ci increased both chromosome aberrations and SCE's. Cultures given a 4-hr pulse with 1.0 μ Ci showed a significant increase in both SCE's and chromosome aberrations. The results indicate that low levels of β -radiation do not increase the incidence of SCE's in human lymphocytes and that several, if not all, the exchanges observed at low levels of β -radiation by autoradiography may be spontaneous events. (17 refs)

- 79-6354 Effects of UV-Light on DNA Synthesis in Photodermatoses. (Eng) Horkay, I. (Dept. Dermatology, Univ. Medical Sch. Debrecen, Debrecen 4012, Hungary); Varga, L.; Tamasi, P.; Gundy, S.; Nagy, E. *Fortschr Onkol* 4: 151-156; 1979.

The repair of UV-induced DNA damage and changes in semiconservative DNA synthesis in the epidermis were studied in eight patients with polymorphic light eruption (PLE), seven patients with porphyria cutanea tarda and erythropoietic protoporphyria (CP), one patient with xeroderma pigmentosum (XP), and six controls without photosensitivity. The percentage of cells showing semiconservative DNA synthesis (indicated by nuclei heavily labeled with thymidine) in the unirradiated, symptom-free skin of patients with photodermatosis did not differ significantly from that in the controls. A slight depression in the percentage of heavily labeled nuclei was observed in specimens of skin irradiated 2 hr previously with three times the minimal erythema dose (MED) of UV light. On skin irradiated daily with five times the MED, the original symptoms of the PLE patients were reproduced, and an erythematous sunburn reaction was observed in both CP patients and controls. The number of heavily labeled cells from such sites was greater than that from unirradiated sites. The av percentage of sparsely labeled epidermal nuclei (indicative of repair DNA synthesis) 2 hr after UV-irradiation with three times the MED did not differ between PLE and CP patients. The av grain-count per cell in PLE was similar to that in controls but was significantly lower in CP and especially lower in XP. Forty-eight hours after irradiation, no repair synthesis was detected in any of the biopsy specimens. The data suggest that some alterations in semiconservative and repair DNA synthesis are present in the epidermis of patients with photodermatosis. (14 refs)

- 79-6355 A Seventh Complementation Group in Excision-deficient Xeroderma Pigmentosum. (Eng) Keijzer, W.

(Dept. Cell Biology and Genetics, Erasmus Univ., P.O. Box 1738, Rotterdam, Netherlands); Jaspers, N. G.; Abrahams, P. J.; Taylor, A. M.; Arlett, C. F.; Zelle, B.; Takebe, H.; Kinmont, P. D.; Bootsma, D. *Mutat Res* 62(1): 183-190; 1979.

DNA excision repair by the cells of a xeroderma pigmentosum patient (XP2BI) was studied. XP2BI cells were sensitive to UV light, compared with cells from an unaffected individual. In a host cell-activation experiment using UV-irradiated simian virus 40 (SV40) circular DNA, the survival fraction of SV40 in XP2BI cells was lower than that in control cells. The UV-stimulated unscheduled DNA synthesis (UDS) pattern of XP2BI cells was characteristic for an excision-deficient XP strain. XP2BI cells did not show detectable excision of endonuclease-susceptible sites. The mol wts of the DNA from XP2BI cells were lower than those of control cells and higher than those of XP variant cells following UV exposure. This response was also characteristic for excision-deficient XP cells. When XP2BI cells were fused with cells from complementation groups A, B, C, D, E, and F, binuclear cells showing UDS levels in the range of normal cells were obtained. Thus, the XP2BI strain represents a new complementation group (group G). (13 refs)

- 79-6356 Enhanced Transformation of Xeroderma Pigmentosum Variant Cells by Ultraviolet Light-irradiated Simian Virus 40. (Eng) Hall, J. D. (Dept. Cellular and Developmental Biology, Univ. Arizona, Tucson, AZ 85721); Tokuno, S. *Cancer Res* 39(10): 4064-4068; 1979.

The role of DNA repair in transformation was investigated by infecting repair-deficient xeroderma pigmentosum (XP) variant cells, XP variant heterozygous cells, and normal human fibroblasts with UV-irradiated simian virus 40. The transformation frequencies obtained were compared with those observed for nonirradiated virus. Although the transformation frequencies of normal fibroblasts and heterozygous XP variant cells infected with irradiated virus were similar to those of normal and heterozygous cells infected with untreated virus, two XP variant cell lines were transformed two- to sevenfold more readily with irradiated virus than with nonirradiated virus. XP variant cells also produced lower than normal quantities of virus following infection with either damaged or undamaged virus, suggesting that increased viral production was not contributing to the increased transformation seen for these cells. The proportion of cells that repaired UV-irradiated simian virus 40 was similar for wild-type and XP variant cells, suggesting that enhanced transformation in the mutant cells was not associated with a reduction in the numbers of cells that repaired damaged virus. (25 refs)

- 79-6357 Defective Recovery of Semi-conservative DNA Synthesis in Xeroderma Pigmentosum Cells Following Split-Dose Ultraviolet Irradiation. (Eng) Moustacchi, E. (Institut Curie, Biologie, Centre Universitaire, Batiment 110, Orsay 91405, France); Ehmann, U. K.; Friedberg, E. C. *Mutat Res* 62(1): 159-171; 1979.

The effects of split- vs single-dose exposures to UV radiation on the recovery of DNA synthesis by two different normal diploid fibroblast strains (GM38 and GM316), xeroderma pigmentosum (XP) cells, and an XP variant (XPV) were compared. After a single-dose exposure, there was a dose-dependent decrease in DNA synthesis in the normal cells for 3-4 hr and then a dose-dependent increase in DNA synthesis after 4-6 hr. The max inhibition of DNA synthesis and delay in recovery were reduced after split-dose exposure, compared with single-dose exposure, and the max level of DNA synthesis was higher. Similar results were obtained with symmetrical and asymmetrical split doses. Caffeine did not produce a synergistic effect with UV radiation after single- or split-dose exposures. XPV cells showed no enhancement in recovery of DNA synthesis after split-dose compared with single-dose irradiation, and caffeine had no effect on the overall pattern of kinetics. Dose fractionation also did not alter the recovery of DNA synthesis in XP cells of complementation groups A and C; similar results were obtained with XP cells of complementation group D. (43 refs)

79-6358 A Study of the Effect of Caffeine upon Excision Repair of Damaged DNA. (Eng) Apfelzweig, R. A. (Div. Cytogenetics and Cytology, City Hope Natl. Medical Center, 1500 E. Duarte Road, Duarte, CA 91010); Teplitz, R. L. *Mutat Res* 62(1): 151-158; 1979.

The effect of caffeine on the excision repair of damaged DNA was studied in peripheral blood lymphocytes from healthy donors. The lymphocytes were treated with UV light or 4-nitroquinoline 1-oxide (4NQO) to produce pyrimidine dimers or adducts, and caffeine (0.75-3.0 mM) was added to some cultures. Lymphocytes from patients with systemic lupus erythematosus (SLE) who had previously demonstrated reduced levels of excision repair under these conditions were also tested. Caffeine did not inhibit repair by normal lymphocytes, and it did not further reduce the reduced repair seen in the cells of the SLE patients. In a series of pulse-chase experiments, some cells were treated with 4NQO and incubated with ³H-thymidine for 3 hr before harvesting; others were given a 13-hr chase in cold thymidine before harvest. The counts per minute per microgram of DNA for both groups were virtually identical, both in the presence and absence of 2.0 mM caffeine. It is concluded that, although single-stranded DNA is available to caffeine during excision repair, DNA polymerase binds with greater affinity and repair continues at an expected rate. (22 refs)

79-6359 Sister Chromatid Exchanges in Lymphocytes Treated with 8-Methoxypsoralen and Exposed to Long-Wave Ultraviolet Light. (Eng) Faed, M. (Cytogenetics Lab., Dept. Pathology, Ninewells Hosp. and Medical Sch., Dundee DD2 1UB, Scotland); Mourelatos, D. In: *Mutagen-induced Chromosome Damage in Man. Proceedings of a Symposium held in Edinburgh, Scotland, July 7-8, 1977*. Medical Research Council (Edinburgh, Scotland): 355 pp.; 52-61; 1978.

Human lymphocytes were obtained from eight psoriasis patients prior to treatment, 11 patients undergoing photochemotherapy with 8-methoxypsoralen (8-MOP) and long-wave UV light (UVA), and 13 healthy adults in order to investigate the effect of this treatment on the induction of sister chromatid exchanges (SCE's). The drug was added to blood from normal donors and, when appropriate, irradiation by UVA followed 30 min later. Samples were collected from treated patients 2 hr after oral ingestion of 8-MOP but before UVA irradiation and again 30 min later following

irradiation. Up to a concentration of 4 µg/ml, 8-MOP alone had no measurable effect on SCE's; but with both 8-MOP and UVA, there was an increase in SCE level related to the dose of 8-MOP. Patients who had not received treatment had SCE levels similar to those of the normal subjects. Treated patients had a marginally higher mean SCE rate (not statistically significant). In vitro irradiation of the blood increased the mean SCE rate to a level that was estimated to indicate a circulating 8-MOP concentration of approx 0.8 µg/ml. The SCE distribution became bimodal as 8-MOP concentration increased, with a significant proportion of the population of cells showing little or no increase in SCE rate. The significance of these observations are discussed, and it is concluded that 8-MOP/UVA therapy appears to have no effect on SCE's in the lymphocytes of psoriasis patients. (9 refs)

79-6360 Neoplastic Transformation and Dose Fractionation: Does Repair of Damage Play a Role? (Eng) Elkind, M. M. (Mammalian Cell Biology Group, Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL 60439); Han, A. *Radiat Res* 79(2): 233-240; 1979.

The induction of neoplastically transformed cells after single and fractionated doses of 50 kV x-rays and fission-spectrum neutrons was measured. Combining the results with those of parallel measurements of cell survival permitted analysis of the possible roles of repair processes in the expression of sublethal and subtransformation damage. It is concluded that subtransformation damage due to x-rays is repaired, although probably more slowly than sublethal x-ray damage. Much less, if any, repair occurs between neutron doses during periods up to 24 hr. It is also concluded that repair of damage does play a role in neoplastic transformation when doses of a sparsely ionizing radiation are fractionated. (12 refs)

79-6361 DNA Repair and Malignant Transformation: Effect of X Irradiation, 12-O-Tetradecanoyl-phorbol-13-acetate, and Protease Inhibitors on Transformation and Sister-Chromatid Exchanges in Mouse 10T1/2 Cells. (Eng) Little, J. B. (Lab. Radiobiology, Dept. Physiology, Harvard Univ., Sch. Public Health, Boston, MA 02115); Nagasawa, H.; Kennedy, A. R. *Radiat Res* 79(2): 241-255; 1979.

The changes which occur in survival and the frequencies of chromosomal aberrations, sister-chromatid exchanges (SCEs), and malignant transformation during recovery from potentially lethal x-ray damage (PLD) in density-inhibited mouse 10T1/2 cells were measured. During the first 4 hr after irradiation, there was a parallel increase in survival, transformation, and SCEs, but a decrease in aberrations. With recovery intervals of 4 to 12 hr, there was no further change in survival or aberrations, but both transformation and SCEs declined markedly. Transformation induced by x-rays alone or combined with application of the tumor promoter, 12-O-tetradecanoylphorbol-13-acetate (TPA), was suppressed by exposure to the protease inhibitor antipain. In PLD-recovery experiments, TPA was found to enhance both spontaneous and direct x-ray-induced (no recovery) SCEs, but to have no effect on recovery-induced SCEs. Two hypotheses are proposed to explain the results: there may be two biologically important classes of DNA lesions and repair processes induced by x-irradiation, one primarily responsible for cell killing and one which leads primarily to mutations and transformation; and mitotic recombination reflected by SCEs is an important step in the expression of radiation damage in terms of transformation, as

it allows segregation of x-ray-induced recessive mutations in daughter cell populations. (39 refs)

- 79-6362 Premature Chromosome Condensation Following X Irradiation of Mammalian Cells: Expression Time and Dose-Response. (Eng) Griffiths, T. D. (Dept. Radiation Biology and Biophysics, Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY 14642); Carpenter, J. G. *Radiat Res* 79(1): 187-202; 1979.

The expression time of premature chromosome condensation (PCC) in Chinese hamster ovary (CHO) cells exposed to 300-kilovolt peak x-rays was investigated in terms of cell-cycle position at the time of exposure. PCC was first detected in the mitosis that followed the second postirradiation (P1) S phase. Thus, cells irradiated in G1 first expressed PCC at the second P1 mitosis, but cells irradiated in G2 did not express PCC until the third P1 mitosis. Cells irradiated in the S phase expressed PCC at the second P1 mitosis with a frequency that was related to the position of the cells in the S phase at the time of exposure, with cells in the first half of the S phase (at the time of exposure) showing a higher frequency than cells positioned in the second half. Thus, DNA replication during the first P1 S phase may be involved in the processing of lesions that eventually give rise to PCC. For cells in G1 at the time of exposure, the D_0 for PCC expression at the second P1 mitosis was around 825 rads, indicating that PCC may play only a minor role in x-ray-induced cell killing. Autoradiographic analysis indicated that approx 50% of the PCC patches scored were replicating DNA at the time condensation was attempted. Daughter cells derived from these cells would suffer loss of genetic material. (44 refs)

- 79-6363 Immunity to Carcinogen-induced Transplantable Fibrosarcomas in B2/B2 Chickens. IV. Effect of Whole-Body Gamma Radiation on Localization and Growth of Intravenously Injected Tumor Cells. (Eng) Palladino, M. A. (Sloan Kettering Inst. Cancer Res., New York, NY); Galton, J. E.; Hochwald, G. M.; Thorbecke, G. J. *J Natl Cancer Inst* 63(3): 737-743; 1979.

Growth of a chemically induced transplantable fibrosarcoma (SCFSI) was observed 2 wk after iv injection of 2×10^7 tumor cells into histocompatible B2/B2 (SC) chickens. About 30% of recipients had tumor nodules in the stomach mucosa and pancreas, 10% in the lungs, and <10% in the heart. No relationship was seen between initial localization of ^{51}Cr -labeled SCFSI cells and sites of subsequent tumor growth: labeled cells localized primarily in liver (50%) and lung (24%). Total-body irradiation with gamma rays greatly enhanced tumor growth in stomach, pancreas, kidney, heart, lung, skeletal muscles, and liver but not in spleen, thymus, bursa, or brain. A single injection of *Corynebacterium parvum* either 1 wk before (-7) or on the day (0) of tumor inoculation did not affect the incidence of tumor growth (75%), whereas two injections of *C. parvum* on both days -7 and 0 completely prevented growth in the irradiated chickens. One-wk-old recipients showed as much tumor growth with or without irradiation, which suggested that the effect of irradiation in older recipients was partly due to damage of the immune response. The iv injection of 50 and 100 mg soybean trypsin inhibitor, 24 and 2 hr, respectively, prior to irradiation (450 rads) did not prevent the increased tumor growth caused by irradiation alone. Tumor cells from two additional SCFS lines (II and IV) also grew in the stomach and pancreas, but SCFSII was never found in heart or skeletal muscle, even in irradiated chickens. (44 refs)

- 79-6364 Failure of Irradiated Beef and Ham to Induce Genetic Aberrations in *Drosophila*. (Eng) Mittler, S. (Dept. Biological Sciences, Northern Illinois Univ., DeKalb, IL 60115). *Int J Radiat Biol* 35(6): 583-588; 1979.

Ham that had been irradiated by electrons [3.7-4.2 megarads (Mrad)] and beef that had been exposed to γ -rays from ^{60}Co (4.7-7.1 Mrad) were fed to *Drosophila melanogaster* males to determine whether meat sterilized by these methods would induce genetic aberrations. The entire spectrum of spermatogenesis was sampled by the brooding technique. yB/sc^yY males that had fed on electron-irradiated ham, ^{60}Co -irradiated beef, thermally preserved beef, or frozen beef showed no significant increase in the loss of X or Y chromosomes or in the nondisjunction of these chromosomes. There was no significant increase in any of the broods. Oregon R males that had spent their entire larval life on irradiated ham or beef, thermally preserved beef, or frozen beef also showed no significant increase in sex-linked recessive lethals. (11 refs)

- 79-6365 The Intercellular Distribution of Mutations Induced in Oocytes of *Drosophila Melanogaster* by Chemical and Physical Mutagens. (Eng) Traut, H. (Institut für Strahlenbiologie, Universität Münster, 4400 Münster, W. Germany). *Genetics* 92(1): 151-160; 1979.

The intercellular distribution of chemically and physically induced mutations in oocytes of *Drosophila melanogaster* was studied. In oocytes from females fed 5-fluorodeoxyuridine (12.5, 50.0, and 81.0 $\mu\text{g}/\text{ml}$), the frequency of mutations (mean, 0.13%) was not increased significantly above the spontaneous rate. There appeared to be little or no difference in the sensitivity of the two X chromosomes to the induction of mitomycin C (MMC: 130.0 $\mu\text{g}/\text{ml}$, po). The results were in accordance with the assumption of a random intercellular distribution of MMC-induced mutations in the oocytes of this species. The data also support the assumption that the mutations induced by x-radiation (2,000 rads, 150 kV) in *Drosophila* oocytes are characterized by a random intercellular distribution. Thus, the ionizations produced by x-radiation represent a good example of randomly distributed mutagenic events. (13 refs)

- 79-6366 Absence of Ecotropic or Recombinant Murine Leukaemia Virus in Preleukaemic and Leukaemic X-Irradiated NZB Mice. (Eng) Harvey, J. J. (MRC Clinical Res. Centre, Harrow, Middlesex, England); Tuffrey, M.; Holmes, H. C.; East, J. *Int J Cancer* 24(3): 373-376; 1979.

NZB mice, which do not normally harbor any detectable ecotropic murine leukemia virus (MuLV) and rarely develop lymphocytic leukemia and/or thymic lymphomas spontaneously, were x-irradiated with a single dose of 630 rads when they were 1 mo old. Eight sick leukemic mice were killed 12-29 wk after irradiation, and eight apparently healthy preleukemic mice were killed 1 mo after irradiation. Bone marrow, spleen, and thymus from these animals were co-cultivated with selectively permissive cell lines, followed by the immunofluorescence test for MuLV-group-specific (MuLVgs) antigen, and the XC test. Xenotropic MuLV, but no ecotropic MuLV, was detected in tissues of both irradiated and control mice. The bone marrow consistently produced most xenotropic MuLV, and the thymus least, regardless of the status of the mice examined. These results do not support the theory that x-irradiation-induced lymphocytic leukemia in NZB mice is caused by the activation of ecotropic or recombinant MuLV. (21 refs)

- 79-6367 Partial Deletion of Chromosome #2 in Myelocytic Leukemias of Irradiated C3H/He and RFM Mice. (Eng) Hayata, I. (Natl. Inst. Radiological Sciences, 4-9-1 Anagawa, Chiba 260, Japan); Ishihara, T.; Hirashima, K.; Sado, T.; Yamagiwa, J. *J Natl Cancer Inst* 63(3): 843-848; 1979.

The chromosomes of seven mice (3 C3H/He males, 1 RFM female, and 3 RFM males) that developed myelocytic leukemias after whole-body irradiation were analyzed using chromosome-banding techniques. Chromosomes number 2 were partially deleted in six mice. Although the deleted number 2 chromosomes varied in size in these mice, one common characteristic was noted in all these deletions: a segment lying between a certain band in the region 2C and a band in the region 2E, including the whole region 2D, was missing. Another consistent abnormality was an addition or a loss of the Y-chromosomes in the fraction of cells in all six males. The RFM female, which had the normal 2 chromosome, had structural abnormalities in chromosomes number 3, 4, 10, 11, 12, and 15 and in the X-chromosome. Of the 20 chromosome pairs, only such chromosomes as 1, 5, 8, 14, 17, and 19 and the Y-chromosome did not have structural abnormalities. The possible role of the partial deletion of the number 2 chromosome was considered in relation to the development of mouse myeloid leukemias. (13 refs)

- 79-6368 Thyroid Neoplasia Following Irradiation for Medulloblastoma: Report of Two Cases. (Eng) Roggli, V. L. (Dept. Pathology, Baylor Coll. Medicine, 1200 Moursund, Houston, TX 77030); Estrada, R.; Fechner, R. E. *Cancer* 43(6): 2232-2238; 1979.

The case reports of two patients (women aged 42 and 22 yr) who developed thyroid neoplasms 14 and 18 yr after treatment with radiation for medulloblastoma are given. One patient had a papillary cancer and the other (the 22-yr-old woman) had multiple adenomas and a Hurthle cell adenoma. In addition, the latter patient had foci of hyperplasia plus a microfollicular transformation that has not been described in association with prior thyroid irradiation. The radiation doses delivered to the thyroid through posterior cervical spinal ports (2,000-3,000 R) fall within the upper range of radiation dosage associated with induction of neoplastic changes within the thyroid. (19 refs)

- 79-6369 Anaplastic Carcinoma of the Thyroid Following External Irradiation. (Eng) Getaz, E. P. (Southeastern Massachusetts Medical Associates, 322 E. Center St., W. Bridgewater, MA 02379); Shimaoka, K.; Rao, U. *Cancer* 43(6): 2248-2253; 1979.

Two cases of anaplastic carcinoma following irradiation of Hodgkin's disease (HD) are reported. A 49-yr-old man was treated at age 5 with 290 rads to the neck for a swelling of 2 yr duration that had been diagnosed as HD. He had also received 12 x-ray treatments from his physician (dosimetry unknown). The patient had smoked heavily for many years prior to the diagnosis and removal of a highly anaplastic thyroid tumor 44 yr later. A 54-yr-old man with severe Coombs-positive hemolytic anemia had been irradiated several times over the previous 19 yr for recurrent lymphadenopathy due to HD. Twelve yr later, he presented with facial and neck pain, dysphagia, and a choking sensation. He was found to have a highly undifferentiated thyroid carcinoma and a bloody pleural effusion secondary to pulmonary metastases. At autopsy, several tumor nodules were found in both the lungs and liver, and

the mediastinal and abdominal lymph nodes were enlarged. The liver nodules and abdominal lymph nodes showed only HD. Eleven other patients with thyroid cancer following irradiation have been reported. The mean age of these patients was 52.4 yr, and the mean latent period was 27.38 yr. Patients with early HD who have undergone irradiation, especially of the neck and mediastinum, must be considered at risk for the development of thyroid malignancy for the rest of their lives. (44 refs)

- 79-6370 Lymphangiosarcoma Arising From Lymphangioma Circumscriptum. (Eng) King, D. T. (Dept. Pathology, Los Angeles County Harbor-UCLA Medical Center, Torrance, CA); Duffy, D. M.; Hirose, F. M.; Gurevitch, A. W. *Arch Dermatol* 115(8): 969-972; 1979.

The development of a lymphangiosarcoma at the site of a preexisting lymphangioma circumscriptum on the lower part of the abdominal wall in a 43-yr-old woman is reported. Approx 15 yr prior to the development of the malignant tumor, this area had received extensive x-irradiation (2,400 rad) during a course of radiotherapy for squamous cell carcinoma of the uterine cervix. The malignant vascular neoplasm found in the abdominal wall was classified as a lymphangiosarcoma because of the presence of lymphatic-type channels and absence of blood cells within the lumina. This is only the second such case to be reported, the first patient also having been exposed to substantial x-ray therapy prior to the development of lymphangiosarcoma. X-irradiation may play a role in the development of this unusual malignant neoplasm, and it seems advisable to avoid exposure of lymphangioma circumscriptum to substantial amounts of radiation. (17 refs)

- 79-6371 Dose Conversion Factors for Radon Daughters. (Eng) Walsh, P. J. (Health and Safety Res. Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830). *Health Phys* 36(5): 601-609; 1979.

Dose-conversion factors consistent with present epidemiological, toxicological, and theoretical evidence about radiogenic lung cancer are suggested for short-lived radon daughters. These dose-conversion factors are based upon risk estimates derived from epidemiological studies that have demonstrated an association between exposure of the lung to ionizing radiation and lung cancer. Various risk estimators, including absolute risk, relative risk, percent increase in excess cases, and excess cases as a fraction of observed cases, are compared. The nature of risk per unit exposure as a function of exposure is shown to be dependent on the risk estimator used. The hypothesis that the excess of observed cases over expected cases is directly proportional to exposure is supported in the range of available data. The nature of exposure response relationships at low exposures is uncertain because of uncertainties in individual exposure estimates. Risks could be overestimated or underestimated depending on the risk estimator used when exposures approach background exposures, especially if background exposures are not included in exposure estimates. (24 refs)

- 79-6372 Collagen Localization in Lung Parenchyma Irradiated by Inhaled $^{239}\text{PuO}_2$ Particles. (Eng) Diel, J. H. (Inhalation Toxicology Res. Inst., Lovelace Biomedical and Environmental Res. Inst., P.O. Box 5890, Albuquerque, NM 87115); Short, R. K. *Radiat Res* 79(2): 417-423; 1979.

The location of the increased lung collagen which has been shown to result from radiation injury to the lung relative to the radiation source was studied. Seven-wk-old Syrian hamsters were exposed by inhalation to a monodisperse aerosol of $^{239}\text{PuO}_2$ particles and sacrificed 136 days later. Excess collagen was found around 6/7 isolated plutonium particles of a single lung. The excess collagen extended to distances of 100-400 μm , averaging $1.6 \pm 0.5 \times$ the background collagen level over a region within 300 μm of the particle. The collagen accumulation within an area containing numerous plutonium particles showed a general increase corresponding to $2.6 \times$ the background level. These regions with numerous particles were invariably associated with foci of obvious structural damage and accumulations of macrophages and other cells and cellular debris. About 30% of the $^{239}\text{PuO}_2$ particles were associated with these foci. The total amount of collagen in the lung as a fraction of the total collagen in a normal lung was estimated to be 1.23. For a given amount of α -emitting material, the effect on lung function due to increased compliance and decreased gas transfer should be less for material contained in a few large particles than for material uniformly distributed throughout the lung. (9 refs)

- 79-6373 Kinetics of Plutonium-239 Metabolism and Absorbed Doses in Dogs after Inhalation Exposure. (Rus) Buldakov, L. A. (No affiliation given); Kalmykova, Z. I. *Radiobiologiya* 19(3): 408-412; 1979.

This study was designed to evaluate the kinetics of plutonium-239 metabolism in dogs after a single inhalation exposure. Polymeric ^{239}Pu was given intratracheally to mongrel dogs at doses of 0.1-10 $\mu\text{Ci}/\text{mg}$. It was found that 11% of the radioactivity was eliminated from the lungs within 1 day of exposure, 22.2% within 103 days, and 94.8% within 2,100 days (the half-life was 555 days). The radionuclide was retained in most of the internal organs for 300-800 days, whereas retention in the skeleton, liver, kidneys, and heart lasted up to 2,100 days. By day 2,100 after exposure, the level of radionuclide in the skeleton and liver was 2.5 and 3 times greater than that in the lungs. Daily excretion of ^{239}Pu in the feces and urine constituted 0.035%-0.15% and 0.021%-0.25% of the overall amount of the radionuclide in the lungs, respectively. There was no correlation between ^{239}Pu levels in the lungs or liver and the amount excreted. (7 refs)

- 79-6374 Isolation and Characterization of Individual Plutonium-bearing Particles in Atmospheric Effluents from a Nuclear Processing Plant. (Eng) Sanders, S. M. (Savannah River Lab., E. I. du Pont de Nemours and Co., Aiken, SC 29801). *Health Phys* 36(3): 371-385; 1979.

A method for isolating and characterizing individual particles containing fissionable materials is described. Membrane filters, used to collect the particles from atmospheric effluents from a nuclear processing plant, are cast into films composed of a polycarbonate matrix containing the particles. Collected particles containing plutonium or other fissionable materials are identified by fission fragment tracks produced by irradiating the film with thermal neutrons. The nature of the fissionable material is identified by coating the film with nuclear track emulsion and measuring the ratio of alpha particle tracks in the emulsion to the fission fragment tracks in the polycarbonate film. Single particles are isolated by excising small squares from the film and are prepared for sizing and electron microbeam analysis by peeling the emulsion off the film square, placing the square on a beryllium sample-mounting

block, and washing the polycarbonate away from the particle. (15 refs)

- 79-6375 Kinetics of Americium-241 Metabolism and Absorbed Doses in Dogs after Inhalation Exposure. (Rus) Buldakov, L. A. (No affiliation given); Kalmykova, Z. I. *Radiobiologiya* 19(3): 462-467; 1979.

The long-term effects of exposure to americium-241 were studied in mongrel dogs. The radionuclide was given intratracheally at doses of 1-100 μCi ; the metabolism of ^{241}Am was monitored for 6.5 yr after a single exposure. Most (54.5%) of the inhaled dose was deposited in the bones. Elimination of the radionuclide from the lung tissue could be described by a three-exponent equation: 54% of the administered radioactivity was eliminated at a constant rate of 0.956 days^{-1} , 17.5% at a rate of 0.0352 days^{-1} , and 5.2% at a rate of $0.00067 \text{ days}^{-1}$ (the half-lives were 0.752, 19.7, and 1,035 days, respectively). The half-life of the radionuclide in the feces and urine was 795 and 950 days, respectively (25.3% and 26.5% of the radioactivity was eliminated in the feces and urine over a period of 2,443 days). The absorbed doses were max in the lungs, lymph nodes, liver, and bones. (7 refs)

- 79-6376 Anaplastic Astrocytoma Following Radiation for a Glomus Jugulare Tumor. (Eng) Preissig, S. H. (Dept. Pathology, Duke Medical Center, Durham, NC 27710); Bohmfalk, G. L.; Reichel, G. W.; Smith, M. T. *Cancer* 43(6): 2243-2247; 1979.

A 43-yr-old man was given 4,480 rads to the right middle and inner ear and temporal bone for a glomus jugulare tumor of the right middle ear. Eight yr later, he developed an anaplastic astrocytoma of the right cerebellar hemisphere. At this time, a third neoplasm, a left carotid body tumor, was demonstrated angiographically. Although radiation can be implicated in the genesis of the glial neoplasm, the presence of two neural crest-derived tumors suggests that a lowered threshold for neoplastic transformation in neuroectodermal cells may have been an additional factor. Long-term follow-up of large numbers of patients with glomus jugulare tumors will be necessary to determine if multiple paragangliomas predispose to radiation-associated gliomas. (37 refs)

- 79-6377 Defective Reactivation of Ultraviolet Light-irradiated Herpesvirus by a Bloom's Syndrome Fibroblast Strain. (Eng) Selsky, C. A. (Dept. Biological Sciences, Stanford Univ., Stanford, CA 94305); Henson, P.; Weichselbaum, R. R.; Little, J. B. *Cancer Res* 39(9): 3392-3396; 1979.

The technique of host cell reactivation of UV-irradiated herpes simplex virus type 1 was used as a measure of the repair capacity of three Bloom's syndrome skin fibroblast strains. At a low multiplicity of infection ($<6 \times 10^{-4}$ plaque-forming unit/cell), reactivation of the virus by the Bloom's syndrome strains was indistinguishable from that by normal strains. Reactivation at higher multiplicities was measured using an infectious centers assay. At 3 plaque-forming units/cell, survival of UV-irradiated herpes simplex virus was higher in all cell strains as a result of the multiplicity reactivation effect. This effect was, however, much smaller in one Bloom's syndrome strain, GM1492, than in either the normal strains or the other Bloom's syndrome fibroblasts. The defect in GM1492 was manifest only at relatively high

multiplicities of infection. Thus, at 0.01 plaque-forming unit/cell, the GM1492 strain appeared normal, using the infectious centers assay. Clonal survival of the UV-irradiated GM1492 fibroblasts was also normal. Caffeine (4 millimolar) had little effect on either virus or cell survival following UV irradiation. The results indicate that Bloom's syndrome strain GM1492 may be deficient in one of the cellular functions responsible for the multiplicity reactivation effect. These effects include complementation and recombinational events. Alternatively, the GM1492 strain may have a defective UV repair system that becomes saturated at high levels of damage. (22 refs)

- 79-6378 **Hyperplasia and Neoplasia of the Intestinal Tract.**
(Eng) Williamson, R. C. (Dept. Surgery, Univ. Bristol, Bristol, England). *Ann R Coll Surg Engl* 61(5): 341-348; 1979.

Mucosal hyperplasia in the remaining gut within 48 hr of partial intestinal loss was investigated using male Sprague-Dawley and Fischer rats. Jejunal transection caused a transient burst of hyperplasia, whereas jejunal resection resulted in an intense and prolonged cell proliferation. Both transection and resection resulted in increased RNA, DNA, and DNA specific activity in the mid-bowel mucosa of parabionts who had undergone abdominal operations, whereas only DNA specific activity was markedly increased in intact parabionts. Elevations in ileal RNA and DNA shortly after jejunal resection exceeded those seen shortly after jejunal bypass, but the responses 1 mo after either procedure were

indistinguishable. Colonic RNA and DNA increased moderately after resection but remained unchanged or even decreased after bypass. Bypass produced prompt and progressive hypoplasia in the mucosa of the excluded jejunal segment. Ileal mucosal DNA and RNA were elevated 48 hr and 1 wk after distal diversion of bile and, to a greater extent, after pancreatobiliary diversion. Values returned to normal thereafter in rats with bile diversion alone but rose progressively after diversion of both secretions. Diversion caused limited increases in colonic nucleic acids and no lasting changes in jejunal values. Azoxymethane (AOM, 10 mg/kg/wk, sc, for 16 wk) caused jejunal hyperplasia followed by the appearance of macroscopic intestinal tumors, and proximal enterectomy alone resulted in ileal hyperplasia which persisted for 3 mo. The number of AOM-induced small bowel tumors per rat was not affected by surgery, but proximal small-bowel resection significantly increased the number of colonic tumors per rat ($p < 0.02$). VIRAL CARCINOGENESIS

- 79-6379 Effect of Viral RNase H on the Avian Sarcoma Viral Genome During Early Transcription In Vitro. (Eng) Friedrich, R. (Inst. Tumormmunology, Univ. Freiburg, D-7800 Freiburg, W. Germany); Moelling, K. *J Virol* 31(3): 630-638; 1979.

The influence of viral RNase H on the transcription of the avian sarcoma virus RNA in a virion-associated reaction was investigated. The ability of RNase H to degrade the RNA moiety of the initially formed RNA-DNA hybrid at the 5' end of the viral genome was greatly dependent on the exact concentration of non-ionic detergent used to activate the reaction. At a detergent concentration optimal for extensive and faithful in vitro transcription of avian sarcoma virus RNA by the virion-associated RNA-dependent DNA polymerase, most of the 5' terminus of the RNA was digested in 30 min at 41 C. At higher than optimal detergent concentrations, however, little of that RNA was digested. It was concluded that removal of the 5'-terminal redundancy in the RNA after its transcription into DNA is a prerequisite for base pairing of the DNA to the 3'-terminal redundant sequence; lack of removal of this sequence leads to incorrect elongation and substantial reduction of DNA synthesis. When tested with a synthetic RNA-DNA hybrid, virion-associated RNase H did not reveal a detergent dependence. (51 refs)

- 79-6380 Virus-specific Messenger RNAs in Permissive Cells Infected by Avian Sarcoma Virus. (Eng) Lee, J. S. (Dept. Microbiology and Immunology, Univ. California, San Francisco, CA 94143); Varmus, H. E.; Bishop, J. M. *J Biol Chem* 254(16): 8015-8022; 1979.

The viral RNA contained in total, membrane-bound, and free polyribosomes isolated from chicken cells infected with wild type avian sarcoma virus (ASV) or deletion mutants of ASV was characterized. The 38S and 21S RNAs, which are presumed to be the messengers for the viral genes *gag/pol* and *src*, respectively, were found largely or entirely in the free polyribosomes. The 28S RNA was contained predominantly in membrane-bound polyribosomes, where it apparently serves as messenger for the viral gene *env*. No additional virus-specific RNAs were identified in either polyribosomes or cytoplasmic extracts. In particular, previous reports of a viral RNA smaller than the 21S species were not confirmed, and no viral RNA that might contain the gene *pol* at its 5' terminus was found. It is concluded that permissive cells infected with ASV contain three major classes of viral mRNA. The glycoprotein product of *env* is synthesized on membrane-bound polyribosomes and is presumably the only integral membrane protein. The products of the other viral genes are synthesized on free polyribosomes and are neither integral membrane proteins nor secretory proteins. (45 refs)

- 79-6381 Cells Transformed by Temperature-Sensitive Mutants of Avian Sarcoma Virus Cause Tumors in Vivo at Permissive and Nonpermissive Temperatures. (Eng) Poste, G. (Dept.

Experimental Pathology, Roswell Park Memorial Inst., Buffalo, NY 14263); Flood, M. K. *Cell* 17(4): 789-800; 1979.

The tumorigenicity of chick embryo (CE) fibroblasts and normal rat kidney (NRK) cells transformed by temperature-sensitive (*ts*) mutants of avian sarcoma virus (ASV) was tested in the chorioallantoic membrane (CAM) of chick eggs, and the resulting tumors were characterized. CE and NRK cells transformed by *ts* mutants of ASV (NY68, LA23, LA24, LA25, LA31, G1201, G1202, G1251, G1253) induced tumors on the CAM at temperatures corresponding to the permissive (35 C) and nonpermissive (41 C) conditions used to induce conditional expression of "transformed" properties in these cells when cultured in vitro. Chick embryo cells infected with transformation-defective mutants of ASV (td101, td108) or RAV-50 were nontumorigenic under the same conditions, as were nontransformed CE and NRK cells. This indicates that the CAM is not an unusually susceptible substrate for cell growth and that the ability of *ts*ASV-transformed cells to form tumors at nonpermissive temperatures reflects their true tumorigenicity. In contrast, a *ts* mutant chemically transformed rat liver cell line, ts-223, only formed tumors on the CAM under permissive conditions. The wild-type parent cells (W-8) of this mutant produced tumors at both permissive and nonpermissive temperatures. Direct implantation of microprobe thermometers into tumors caused by *ts*ASV-transformed cells at nonpermissive temperatures confirmed that tumor formation occurred in a stable temperature environment and was not due to temperature fluctuations, which might have created semi-permissive or permissive conditions for tumor growth. Cells isolated from tumors formed at nonpermissive temperatures and recultured in vitro displayed temperature-dependent hexose transport and colony formation in agar similar to the original parent cell inoculum. Similarly, virus recovered from tumors at nonpermissive temperatures retained the *ts* mutation. (52 refs)

- 79-6382 A Normal Cell Protein Similar in Structure and Function to the Avian Sarcoma Virus Transforming Gene Product. (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO 80262); Erikson, E.; Purchio, A. F.; Brugge, J. S.; Erikson, R. L. *Proc Natl Acad Sci USA* 76(7): 3159-3163; 1979.

A protein from normal cells that is closely related to the avian sarcoma virus (ASV) transforming gene product pp60^{src} was further characterized. This normal cellular protein, which was found in both avian and mammalian cells and was tentatively designated pp60^{src}, was detected by immunoprecipitation of radiolabeled cell extracts with serum derived from both mice and rabbits bearing ASV-induced tumors. The normal cell pp60^{src} is a 60,000-dalton phosphoprotein that is structurally similar, but not identical, to viral pp60^{src}. The phosphorylation patterns of the normal cell and viral proteins are also similar: both contain two major phosphorylated residues, a phosphoserine located on the NH₂-terminal 60% of the polypeptide and a phosphothreonine present on the COOH-terminal 40% of the molecule. In addition, the normal cell pp60^{src} from both chicken and mammalian cells

appears to have an associated protein kinase activity analogous to that previously described for the viral pp60^{src}. The normal cell protein pp60^{src} and the ASV transforming protein pp60^{src} may be involved in normal cellular growth and neoplastic disease, respectively. (28 refs)

- 79-6383 Characterization of an Immune Complex Kinase in Immunoprecipitates of Avian Sarcoma Virus-transformed Fibroblasts. (Eng) Richert, N. D. (Div. Cancer Biology and Diagnosis, Lab. Molecular Biology, NCI, Bethesda, MD 20205); Davies, P. J.; Jay, G.; Pastan, I. H. *J Virol* 31(3): 695-706; 1979.

Kinase activity detected in immune complexes containing the *src* gene product of the avian sarcoma virus (ASV) was characterized using trichloroacetic acid precipitation on filters. The enzyme reaction required either Mg²⁺ or Mn²⁺, but was inactive with Ca²⁺. The kinetics of the phosphorylation reaction indicated a transient enzyme activity limited by rapid substrate-dependent inactivation of the enzyme. A variety of nucleoside and deoxyribonucleoside triphosphates (dATP, ATP, GTP, dGTP, TTP, dCTP) served as phosphoryl donors. The phosphorylation of IgG was inhibited by the presence of nucleoside diphosphate, and deoxyribonucleoside diphosphates could either stimulate or inhibit the kinase reaction depending on the concentration used. The unusual enzymatic properties of the immune complex kinase raise the possibility that the enzyme does not function as a protein kinase in vivo, but rather may belong to a different class of kinases (nucleotide kinases) which phosphorylate IgG when immunoprecipitated with immune serum. (37 refs)

- 79-6384 Avian Erythroblastosis Virus: Transformation-specific Sequences from a Contiguous Segment of 3.25 kb Located in the Middle of the 6-kb Genome. (Eng) Lai, M. M. (Dept. Microbiology, Univ. Southern California, Sch. Medicine, 2011 Zonal Ave., Los Angeles, CA 90033); Hu, S. S.; Vogt, P. K. *Virology* 97(2): 366-377; 1979.

Several foci of chicken embryo fibroblasts transformed by avian erythroblastosis virus (AEV) strain ES-4 produced virus progeny containing the RNA of the replication-defective AEV in excess of the helper virus RNA. The size of AEV RNA was determined by methylmercury-agarose gel electrophoresis and electron microscopy to be 28S or 6 kilobases (kb). About 40% to 45% of this RNA was homologous by RNA-DNA hybridization to the RNA of other chicken leukosis and sarcoma viruses; the rest of the genome was AEV specific. These AEV specific sequences, which presumably contain the genetic information responsible for transformation, formed a contiguous stretch of 3.25 kb, located by heteroduplex mapping in the center of the 6 kb genome; on either side were the two segments (1.06 kb at the 3' end and 1.64 kb at the 5' end) which were homologous to the genome of avian sarcoma virus. From the length of the region showing homology between AEV and avian sarcoma virus at the 5' end of the genome and from the known sequence composition of the AEV-specific 75K protein, it can be deduced that the initiation point for the N terminus of the *gag* protein p19 is located about 1.0 kb from the 5' end of the genome in avian oncoviruses. Nonproducing AEV-transformed chicken embryo fibroblasts were also isolated. Infectious AEV could be rescued from these cells only with chicken leukosis viruses; unrelated avian retroviruses were ineffective, probably because AEV requires complementation in the *gag* and *pol* genes, in addition to *env*. (43 refs)

- 79-6385 Proliferation of Rous Sarcoma Virus-infected, But Not of Normal, Chicken Fibroblasts in a Medium of Reduced Calcium and Magnesium Concentration. (Eng) Balk, S. D. (Dept. Pathology, Faculty Medicine, Univ. Manitoba, Winnipeg, Manitoba, Canada R3E 0W3); Polimeni, P. I.; Hoon, B. S.; LeSturgeon, D. N.; Mitchell, R. S. *Proc Natl Acad Sci USA* 76(8): 3913-3916; 1979.

The roles of calcium and magnesium in the initiation of cell replication were studied. In the presence of a physiological concentration of magnesium, reduction of the calcium concentration from a physiological level (1.2 mM) to 0.125 mM resulted in a significant decrease in the proliferation of normal chicken embryo fibroblasts, but not of neoplastic, Rous sarcoma virus-infected fibroblasts. Reduction of the magnesium concentration to 0.05 mM in the presence of a physiological concentration of calcium had a similar effect. In a culture medium containing reduced concentrations of both calcium (0.20 mM) and magnesium (0.05 mM), normal fibroblasts were maintained without proliferation, whereas Rous sarcoma virus-infected fibroblasts continued to proliferate actively. The cytosol concentrations of ionized calcium and magnesium are known to be regulated by a balance between net passive influx and active extrusion and sequestration. On the basis of this consideration and the present findings, it is hypothesized that: (1) fibroblast replication is initiated when cytosolic concentrations of calcium, magnesium, or both rise above a critical level. (2) Autonomous initiation of replication of neoplastic fibroblasts is a result of failure of cytoplasmic divalent cation homeostasis; alternatively, sarcoma virus infection may endow cells with a divalent cation-independent mechanism that bypasses an initiation mechanism that is, normally, divalent cation-dependent. (3) Proliferation of normal fibroblasts is controlled by extracellular matrix components that interact with cell surfaces in a manner that limits the permeability of plasma membranes to divalent cations or otherwise functions to lower cytosol divalent cation concentrations. (28 refs)

- 79-6386 Morphological Revertants of an Avian Sarcoma Virus-transformed Mammalian Cell Line Exhibit Tumorigenicity and Contain pp60^{src}. (Eng) Lau, A. F. (Dept. Microbiology, Univ. Minnesota Medical Sch., Minneapolis, MN 55455); Krzyzek, R. A.; Brugge, J. S.; Erikson, R. L.; Schollmeyer, J.; Faras, A. J. *Proc Natl Acad Sci USA* 76(8): 3904-3908; 1979.

The biological and biochemical properties of Rous sarcoma virus-transformed and revertant field vole cells were investigated. Revertant vole cells appear morphologically similar to normal, uninfected cells, yet, like transformed vole cells, they are fully capable of growing in agar suspension and producing tumors in athymic nude mice. These highly tumorigenic, yet morphologically normal appearing, vole cells express viral-specific antigens such as the *gag* gene product (Pr76) but lack the *env* gene protein (gp85). Moreover, they contain the *src* gene protein, pp60^{src}. These results support the concept of the pleiotropic nature of the *src* gene product and in addition suggest that pp60^{src} may have multiple mechanisms of action. With this revertant cell system it may be feasible to distinguish between those biochemical functions of the *src* gene product that are important for tumorigenicity in vivo and those that are related to in vitro morphological transformation. (26 refs)

- 79-6387 Regulation of the Proliferative Response in Rous Sarcoma Virus Transformed Chicken Embryo

Fibroblasts by Serum and Multiplication-stimulating Activity (MSA). (Eng) Knauer, D. J. (Sch. Life Sciences, Univ. Nebraska, Lincoln, NE 68588); Smith, G. L. *J Cell Physiol* 100(2): 311-322; 1979.

The growth stimulatory response of transformed chicken embryo fibroblasts to serum and purified multiplication-stimulating activity (MSA), a polypeptide growth factor, was investigated. A temperature sensitive mutant of Rous sarcoma virus (tsNY68) was used to obtain cultures of quiescent virus-infected chicken embryo fibroblasts arrested by serum starvation at the nonpermissive temperature. Upon shift to the permissive temperature, these cells enter the replicative cell cycle. These changes occur in the absence of serum, and the cells become morphologically transformed within 8-10 hr after the temperature shift. Entry into the S phase temporally resembles that of normal quiescent fibroblasts stimulated with serum. The presence of serum in the medium enhanced the proliferative response of quiescent infected cells shifted to the permissive temperature over those shifted in the absence of serum. In contrast, infected cultures shifted in the presence of MSA showed no significant increase in cell number above that of cultures shifted in serum-free medium. Labeled MSA binding experiments showed that this lack of response was not due to a loss of MSA receptors on the cell surface, since transformed cells were still capable of binding MSA at the same level as normal cells. The results are consistent with the hypothesis that the set of biochemical events initiated by MSA in normal cells are turned on in infected cells shifted to the permissive temperature by the activation of the src gene product. (33 refs)

79-6388 Embryonal and Tumor-specific Plasma Membrane Antigens of Rous Sarcoma Virus Transformed Fibroblasts. (Eng) Prat, M. (Cattedra di Istologia e Embriologia, Università di Trieste, Trieste, Italy); Tarone, G.; Comoglio, P. M. *Ital J Biochem* 28(2): 124-127; 1979.

The antigenic composition of baby hamster kidney (BHK)-C13/21 fibroblasts transformed by Rous sarcoma virus (RSV; B46 cells) was investigated using antisera raised in rabbits immunized with B46 cells. When the serum was adsorbed with normal hamster cells (C13 cells), it had no cytotoxic activity against them but killed hamster cells transformed by murine sarcoma virus (MuSV), simian virus 40, polyoma virus, and RSV; a common tumor-associated antigen thus appears to be expressed on all the transformed hamster cells. Ten-day-old hamster embryo cells were perfectly lysed by the anti-B46/C13 adsorbed serum. This indicates that, following viral transformation, a cellular gene silent in normal cells is derepressed. Anti-B46/C13 adsorbed sera which were further adsorbed with polyoma virus-transformed cells had no cytotoxic activity to MuSV- or polyoma virus-transformed cells but still reacted with B46 cells. Thus B46 cells express a second tumor antigen, VCSA (virus cell surface antigen), which is specifically induced by the transforming virus. RSV-transformed quail and chicken cells were also lysed by the anti-VCSA sera, while uninfected chick embryo fibroblasts and chick embryo fibroblasts infected by a transformation-defective mutant of RSV were not lysed. Thus VCSA expression is under the control of the RSV genome and is not a virion structural protein. (6 refs)

79-6389 Shedding of Hyaluronate from the Cell Surface of Rous Sarcoma Virus-transformed Chondrocytes. (Eng) Mikuni-Takagaki, Y. (Developmental Biology Lab., Massachusetts General Hosp., Boston, MA 02114); Toole, B. P. *J Biol Chem* 254(17): 8409-8415; 1979.

Transformation of cultured chick embryo chondrocytes with Rous sarcoma virus increased incorporation of isotopic precursors into hyaluronate and decreased incorporation into chondroitin 6-sulfate. Chemical measurements of these glycosaminoglycans showed corresponding changes. Comparison of the kinetics of glycosaminoglycan production by normal and Rous sarcoma virus-transformed chondrocytes demonstrated that the rate of accumulation in the medium was similar in both cultures and that approx 50% of total glycosaminoglycan produced by the normal chondrocytes, but only 10% of that from the transformed cells, accumulated in the cell layer. Prelabel-chase experiments indicated that cell surface-associated hyaluronate, as measured by release from the cell layer by trypsin treatment, was shed rapidly into the medium and accounted for all of the hyaluronate which accumulated there. It was concluded that accumulation of cell surface-associated glycosaminoglycan is dramatically reduced in Rous sarcoma virus-transformed chondrocytes and that hyaluronate produced by the transformed chondrocytes is first deposited in the cell-associated extracellular compartment and then rapidly shed into the medium, rather than being secreted directly into the medium. (67 refs)

79-6390 Avian Sarcoma Virus Envelope Glycoprotein (gp85) Specifically Binds Chick Embryo Fibroblasts. (Eng) Moldow, C. F. (Dept. Medicine, Univ. Minnesota Sch. Medicine, Minneapolis, MN 55455); Reynolds, F. H.; Lake, J.; Lundberg, K.; Stephenson, J. R. *Virology* 97(2): 448-453; 1979.

The binding of ¹²⁵I-labeled highly purified Prague (Pr) strain Rous sarcoma virus (RSV) subgroup C envelope glycoprotein (gp85) to C/E chicken embryo fibroblasts (CEF) was linear with respect to gp85 concentration and relatively independent of temperature between 4 C and 37 C. At saturation 1 x 10⁵ to 2 x 10⁵ molecules of gp85 were bound per cell. Genetically resistant C/C CEF bound considerably less glycoprotein. The specificity of the binding activity was indicated by the fact that neither C/E nor C/C CEF exhibited detectable binding of Rauscher murine leukemia virus envelope glycoprotein (gp70). Of the avian viruses tested, only those with subgroup C host range inhibited binding of ¹²⁵I-labeled Pr-RSV-C gp85 by C/E CEF. These findings indicate that Pr-RSV-C gp85 can be purified with retention of biological binding activity and may be a useful reagent for further analysis of the early events of avian RNA tumor virus infection. The use of this reagent should make possible the purification and analysis of cellular receptor sites for avian type C viral envelope glycoproteins. (13 refs)

79-6391 Alignment of the Restriction Map of Mouse Adenovirus FL with that of Human Adenovirus 2. (Eng) Larsen, S. H. (Dept. Microbiology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205); Margolske, R. F.; Nathans, D. *Virology* 97(2): 406-414; 1979.

A restriction map of mouse adenovirus strain FL (AdFL) was constructed based on sites of cleavage of AdFL DNA by 19 restriction endonucleases. The AdFL map was oriented with respect to that of human adenovirus type 2 (Ad2) by identifying which end of AdFL DNA is retained in virions with incomplete genomes compared with the end retained by Ad2 defective particles as previously determined. The AdFL map was also oriented to that of Ad2 by locating small regions of DNA homology in the AdFL and Ad2 cleavage maps. Cross-hybridization tests with a series of restriction fragments of each viral DNA revealed two regions of homology between Ad2 and AdFL DNA, which corresponded to the posi-

tions of the Ad2 hexon gene and an Ad2 hexon-associated protein gene. The regions of homology between the hexon genes of AdFL and Ad2 are more extensive than between the genes for hexon-associated protein. (12 refs)

- 79-6392 Ultraviolet Radiation Induction of Endogenous Murine Type C Virus. (Eng) Hellman, K. B. (Bureau Radiological Health, FDA, Rockville, MD 20857); Brewer, P. P. *Mutat Res* 62(2): 205-212; 1979.

The dose-response relationship for UV induction of mammalian type C virus was studied using the A1-2 cell line, a clonal sarcoma-positive, helper-negative derivative of adult BALB/c mouse peritoneal cells transformed by Gazdar murine sarcoma virus. Irradiation of log-phase A1-2 cells induced endogenous xenotropic type C virus, as determined by MSV focus assay on NRK cells. Induction was observed from 24 to 72 hr, with optimal induction occurring at 48 hr. The number of virus-induced cells increased with radiation exposure, reaching an optimal fourfold increase at 2 J/m² and decreasing with higher radiation doses. Although the fraction of A1-2 cells induced to release virus by UV radiation (0.17%) was less than that observed after treatment with 5-iodo-2-deoxyuridine (3.0%) or 5-bromo-2-deoxyuridine (0.46%), the use of the sensitive infectious center assay demonstrated reproducible UV induction. Examination of A1-2 cell survival following irradiation showed that optimum viral induction occurred at a UV exposure corresponding to the edge of the shoulder of the survival curve, suggesting that UV sensitivity of the host cell may be a factor limiting the level of induction. Since less radiation was required for viral induction than for inactivation of colony-forming ability, viral induction may be a more sensitive dosimeter of in vitro UV bioeffects than cell survival for this system. (26 refs)

- 79-6393 Generation of a Mouse Mammary Tumor Virus (MMTV) Pseudotype of Kirsten Sarcoma Virus and Restriction of MMTV *gag* Expression in Heterologous Infected Cells. (Eng) Schochetman, G. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Long, C.; Massey, R. *Virology* 97(2): 342-353; 1979.

C3H mouse mammary tumor cells producing mouse mammary tumor virus (MMTV) were cocultivated with nonproducer mouse cells (KNIH) transformed by Kirsten sarcoma virus (KiSV). These cocultivated cells were then treated with mitomycin C and overlaid onto human embryonic skin and muscle cells. The virus resulting from this cocultivation could be titrated in a focus-forming assay on Fischer rat embryo (FRE) cells exhibiting one-hit kinetics. Furthermore, focus formation on FRE cells was neutralized specifically by antiserum directed against MMTV and the major MMTV external glycoprotein gp52, but not against a broadly reactive antiserum directed murine leukemia virus (MuLV) gp70 and MMTV gp36, p27, p14, and p10. These results demonstrated the generation of a KiSV(MMTV) pseudotype; in addition, gp52 was shown to be a target antigen for neutralization of MMTV. This pseudotype possessed a wide host range, transforming cells of human, rat, mouse, mink, and rabbit origin. MMTV but not MuLV antigen expression was demonstrated in the KiSV(MMTV) pseudotype-infected cells. Analysis of intracellular MMTV protein synthesis in these in vitro-infected cells indicated that the low yield of extracellular MMTV produced by the transformed cells may be the result of poor expression of the MMTV *gag* precursor polyprotein relative to the expression of the *env* gene polyprotein. These studies provide the basis for an in vitro infectivity assay for neutralization and host range studies of MMTV. (23 refs)

- 79-6394 Intracisternal A Particle-specific DNA Sequences in Mammary Tumor Cells, Hybrids, and Cybrids Derived from Laboratory Mice and from Feral Mice of *Mus musculus* and *Mus cervicolor*. (Eng) Yang, S. S. (Lab. Cell Biology, NCI, Bethesda, MD 20014); Wivel, N. A. *Virology* 96(1): 166-176; 1979.

DNA sequences homologous to murine intracisternal A-particle (IAP) complementary DNA (cDNA) were examined by nucleic acid hybridization, using mammary tumor (MT) cells, hybrids, and cybrids derived from laboratory mice and from feral mice of *Mus musculus* and *Mus cervicolor*. The radioactive cDNA probe was synthesized by the endogenous reverse transcriptase reaction in purified mammary tumor IAP. Given the copy numbers of IAP-specific DNA sequences obtained in the various parent cells, hybrids, and cybrids and the thermal stability characteristics of the DNA duplexes, two distinct phenomena were observed. First, one phenotypically negative recipient cell line, 3T3-4EF, had only one to two copies of IAP-specific DNA sequences per haploid genome prior to fusion. When this line was fused to MT cytoplasts (enucleated cells) containing IAP, the resulting cybrid cells were found to have about 10 copies of IAP-specific DNA sequences, which were localized by the Hirt procedure in the detergent-insoluble fraction of the nuclear DNA. Thus, the continuous replication of IAP in the MT x 3T3-4EF cybrids was associated with an increase in the number of IAP-specific DNA sequences in the cell genome. Second, another phenotypically negative recipient cell line, 116C, had about four copies of IAP-specific DNA sequences per haploid genome prior to fusion. Following fusion with MT cytoplasts, the resulting MT x 116C cybrids did not show any increase in the number of IAP-specific DNA sequences, even after IAP replication had become overt, continuous, and nonsegregated. The distribution of DNA copies in the various *Mus musculus* and *Mus cervicolor* laboratory and feral mouse cells indicates that the IAP genome has been conserved in spite of the divergence of the two species. (32 refs)

- 79-6395 Effect of Dexamethasone on Expression of Endogenous Mouse Mammary Tumor Virus Sequences in BALB/c Tumor Cell Lines. (Eng) Dudley, J. P. (Dept. Microbiology, Univ. California Sch. Medicine, San Francisco, CA 94143); Butel, J. S. *Virology* 96(2): 453-462; 1979.

Two complementary DNA (cDNA) probes representative of either the entire mouse mammary tumor virus (MMTV) RNA genome or its poly(A)-adjacent sequences were used to monitor any changes that occur at the level of viral RNA accumulation following dexamethasone (DXS) treatment of BALB/c mammary tumor cell lines. Lines that contained only endogenous MMTV sequences responded to DXS treatment with minimal (approx 2-fold) increases in MMTV RNA. This is in marked contrast to the 10- to 20-fold increases observed with cell lines harboring exogenous MMTV variants. Comparison of hybridization results obtained with the two cDNA probes suggests that the DXS response of BALB/c lines is also qualitatively different from that of exogenous MMTV-producer cell lines. Thermal stability studies suggested a 2%-3% divergence between the RNA sequences of endogenous BALB/c and exogenous C3H viruses, with the 3' end of the viral RNA appearing to be conserved relative to the rest of the genome. (33 refs)

- 79-6396 Immunocytochemical Distribution of Mouse Mammary Tumor Virus Antigens in BALB/cC3H Mammary Epithelium. (Eng) St. George, J. A. (Dept. Anatomy, Sch.

Veterinary Medicine, Univ. California, Davis, CA 95616); Cardiff, R. D.; Young, L. J.; Faulkin, L. J. *J Natl Cancer Inst* 63(3): 813-820; 1979.

Using polyvalent anti-MuMTV serum and indirect immunoperoxidase techniques, the distribution of mouse mammary tumor virus (MuMTV) antigens was studied in normal, preneoplastic, and neoplastic mammary epithelia from female BALB/cfC3H mice. The MuMTV antigens were on the apical surface, in focal cytoplasmic aggregates, or diffused throughout the infected cells. As many as 70% of the cells in adenocarcinomas and 100% of all cells in preneoplastic hyperplastic alveolar nodules contained MuMTV antigens. Comparable percentages of cells from mammary glands of multiparous mice were MuMTV-positive. Some mammary tissues of nulliparous and primiparous mice did not contain detectable MuMTV antigen. The MuMTV antigen-containing cells in lactating mammary glands tended to be in discrete lobuloalveolar clusters surrounded by antigen-negative alveoli. The percentage of MuMTV-positive cells in a given gland was proportional to the amount of virus found in the animal's milk. (30 refs)

79-6397 In Vitro Infectivity Assay for Mouse Mammary Tumor Virus. (Eng) Vacquier, J. P. (Dept. Pathology, Sch. Medicine, Univ. California, Davis, CA 95616); Cardiff, R. D. *Proc Natl Acad Sci USA* 76(8): 4117-4121; 1979.

Studies of mouse mammary tumor virus (MMTV) have been impeded by the lack of an in vitro infectivity assay. A rapid, quantitative in vitro assay for MMTV infectivity based on the detection of positively staining foci by immunoperoxidase was developed. This assay and a 50% end-point titration of MMTV infectivity gave identical virus titers. Infection of a rat hepatoma cell line, a feline kidney cell line, and a normal murine mammary gland cell line by virus from the mouse mammary tumor GR3A cell line was linear with respect to virus concentration. The infectious titers obtained in both homologous and heterologous cell lines were not significantly different, demonstrating a lack of host range specificity. Virus infectivity was inactivated by heating at 55 C and by ultraviolet irradiation. Rabbit anti-MMTV serum neutralized the infectivity with a 50% neutralization end point of 1:5000. Applications of this assay to the study of the immunological, biological, and biochemical characteristics of MMTV are discussed. (25 refs)

79-6398 Levels of Mammary Tumor Virus Proteins (MTVp27 and MTVgp52) in the Milk of Low and High Mammary Cancer Mouse Strains of Japanese Origin Compared with European and American Strains. (Eng) Imai, S. (Dept. Pathology, Nara Medical Coll., 840 Shijo-cho, Kashihara-shi, Nara-Ken 634, Japan); Hilgers, J. *Int J Cancer* 24(3): 359-364; 1979.

A competition radioimmunoassay for purified murine tumor virus (MTV) proteins MTVp27_{gag} and MTVgp52_{env} was used to measure the amounts of these proteins in the milk of mice of various Japanese, European, and American strains. The SL/NiA strain was positive for MTV-p27 in the milk (10-100 nanograms(ng)/mg). Foster nursing of this Japanese strain on BALB/c mice did not lead to the disappearance of MTVp27 antigen expression, indicating that the MTV is genetically transmitted in this strain. Other high mammary cancer strains had large amounts of MTV in their milk; these included FM/JmsA [1,500-4,500 and 2,600-18,000 ng/mg milk protein of MTVp27 and MTVgp52, respectively], C57BL/6MsMtA (1,500-1,900 and

1,400-7,600 ng/ml), and DD/Tbr (470-3,300 and 670-6,700 ng/mg). These levels of MTVp27 and MTVgp52 were comparable to those of the C3H/HeA, A/BrA, and R111/SeA strains. They were generally somewhat lower than in BALB/cHeA strain mice foster-nursed on high mammary cancer strain mice. BALB/cHeA strain milk showed some positivity for both MTV proteins at the borderline of detection (0.1 ng/mg protein). (C57BLxC3Hf)F1 hybrid mice had even less MTVp27 and gp52 in their milk than the C3Hf strain mice, permitting genetic analysis of the gene for this suppression by the C57BL genotype. These results show that the general rule that high mammary cancer strains have a high level of MTV proteins in their milk applies to the Japanese strains and that foster nursing leads to disappearance of these high levels. 79-6399 Reticulum Cell Neoplasms Induced in C57BL/6 Mice by Cultured Virus Grown in Stromal Hematopoietic Cell Lines. (Eng) Haas, M. (Dept. Cell Biology, Weizmann Inst. Science, Rehovot, Israel); Meshorer, A. *J Natl Cancer Inst* 63(2): 427-439; 1979.

The isolation and properties of 31 adherent cell lines established from the spleens, lymph nodes, and bone marrow of C57BL/6 mice carrying radiation leukemia virus-induced reticulum cell neoplasms (RCN) are reported. The cell lines had a stable epithelial or fibroblastoid morphology. Supernatant virus from these lines induced splenic and lymph node RCN in 100% of inoculated C57BL/6 mice within 30 days. The disease was generalized and involved many organs. The monolayer cells themselves were not tumor cells, and they induced RCN through infection of the host with RCN virus. Simultaneous inoculation of in vitro-grown RCN-inducing virus and thymic lymphosarcoma virus induced each disease independently with no changes in incidence, latency period, and organ involvement. No mutual enhancement or inhibition was found, which indicates that two separate mechanisms of action were involved. Reextraction of the viruses from spleen, lymph nodes, and thymus gland indicated the specific organotropism of each agent. All the adherent cell lines that were derived from hematopoietic tissues produced ample potent RCN-inducing virus. This high success rate suggests that in the hematopoietic organs, the stromal fibroblastoid cells are a natural habitat for RCN-inducing virus. RCN-inducing viruses may well be synthesized in these hematopoietic stromal cells. RCN-inducing virus from culture supernatants contained high-titer infectious ecotropic and xenotropic virus that was titrated. The cultures are being used to clone the RCN-inducing virus and to establish the virologic and molecular properties that endow it with specific RCN-inducing capacity. (41 refs)

79-6400 Thermolabile Protein Kinase Molecules in a Temperature-sensitive Murine Sarcoma Virus Pseudotype. (Eng) Sen, A. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD 20205); Todaro, G. J.; Blair, D. G.; Robey, W. G. *Proc Natl Acad Sci USA* 76(8): 3617-3621; 1979.

Murine sarcoma virus-associated protein kinases that bind to actin have been purified by affinity chromatography on actin coupled to Sepharose. Heat inactivation studies showed the presence of thermolabile enzyme activity in pseudotypes containing a temperature-sensitive mutant of murine sarcoma virus (MSV) but not in two independent wild-type MSV pseudotypes. Studies with Sephadex G-75 column fractions showed that a low mol wt form, approx 15,000, is the major thermolabile kinase in the temperature-sensitive MSV virions. Antibodies raised against the MSV-coded

p60 protein, when added to the in vitro reaction mixtures, showed specific phosphorylation of the IgG heavy chain and a simultaneous reduction in the extent of phosphotyrosine phosphorylation catalyzed by the various MSV pseudotype kinases. Thus a transforming retrovirus-coded enzyme activity that interacts directly with a major cytoskeletal protein and whose activity parallels the transforming ability of a conditional MSV mutant was identified. - 79-6401** Abelson Murine Leukemia Virus-infected Cell Lines Defective in Transformation. (Eng) Sacks, T. L. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD 20014); Hershey, E. J.; Stephenson, J. R. *Virology* 97(2): 231-240; 1979.

The isolation of two distinct classes of transformation-defective cell lines nonproductively infected with Abelson leukemia virus (AbLV) is described. One group was selected as spontaneous revertants of an AbLV-transformed mink cell line. Mutants of this group were defective both in transformation and in expression of gag gene proteins (p15 and p12) encoded by the amino terminal region of the AbLV genome. Superinfection of such cell clones by various helper viruses led to rescue of wild-type AbLV, indicating that the transformation defect in the morphologically reverted clones involves a defect in cellular genes influencing transformation rather than in the viral genome itself. Mutants of the second group were isolated by screening single cell clones, newly infected by AbLV pseudotype virus, for expression of p12 antigen in the absence of either transformation or virion production. Twenty such mutants were selected. All clones except one expressed high levels of p15 and p12 in the absence of detectable levels of other gag gene-coded structural proteins. One clone was also positive for envelope glycoprotein (gp70) apparently encoded by a replication-defective helper virus mutant. In the second group of mutant cell clones, attempts to isolate wild-type AbLV were unsuccessful. Moreover, transformation could be induced following superinfection with wild-type AbLV pseudotype virus but not with superinfection by helper virus alone. The possibility that these latter mutants may be viral rather than cellular in origin is discussed. (20 refs)

- 79-6402** Properties of DNA-dependent RNA Polymerases from Spleen of Rats Inoculated with Rauscher Leukemia Virus. (Rus) Pravdina, N. F. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Veselovskaia, T. V.; Galegov, G. A. *Biokhimiia* 44(6): 1137-1144; 1979.

This study was designed to evaluate the changes in RNA polymerase activity during leukemia development. RNA polymerase was isolated from the spleens of BALB/c mice inoculated ip with 0.25 ml of supernatant obtained after centrifugation of 10% spleen cell homogenate from mice with Rauscher viral leukemia. The spleen of intact (leukemia-free) mice contained three peaks of RNA polymerase activity which corresponded to RNA polymerases A(I), A(II), and B; all three polymerases had similar, relatively low activity. On day 3 after inoculation spleen wt increased to 200 g and the chromatographic profile and activities of polymerases were similar to those in controls. At early stages of leukemia development (day 5: spleen wt increased to 300 mg), there was a marked, twofold increase of RNA polymerase B activity. Progressive development of leukemia (increase of spleen wt to >600 mg) was associated with the increase of RNA polymerase activity and appearance of RNA polymerase C. In vitro incubation of polymerases with the semisynthetic antibiotic

dihydrorifampicin resulted in a 50% inhibition of RNA polymerase activity. (20 refs)

- 79-6403** Preparation of Syngeneic Tumor Regressor Serum Reactive with the Unique Determinants of the Abelson Murine Leukemia Virus-encoded P120 Protein at the Cell Surface. (Eng) Witte, O. N. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Rosenberg, N.; Baltimore, D. *J Virol* 31(3): 776-784; 1979.

Syngeneic tumor regressor serum reactive with the Abelson murine leukemia virus (A-MuLV)-specified P120 (anti-AbT sera) were produced in C57L/J mice. Of many mouse strains tested, only C57L/J reproducibly rejected syngeneic A-MuLV-induced tumor cells; after multiple immunizations, their sera would immunoprecipitate both P120 and Moloney-MuLV (M-MuLV) proteins. Using labeled A-MuLV-induced nonproducer cells, only P120 could be detected using anti-AbT sera, suggesting that it may be the only A-MuLV-specified protein. Reactivity of anti-AbT sera with P120 was not blocked by M-MuLV virion proteins, implying that the sera recognize a portion of P120 that is not homologous to any M-MuLV product. Anti-AbT sera stained the surface of live A-MuLV-transformed nonproducer cells in a two-stage immunofluorescence assay, and such staining was not blocked by M-MuLV protein. Also, intact A-MuLV-transformed cells absorbed much of the reactivity of certain anti-AbT sera for P120. Thus, a portion of P120 appears to be exposed on the surface of transformed cells. P120 lacked detectable carbohydrate, was not affected by endoglycosidase H, and could not be labeled by lactoperoxidase-catalyzed iodination, indicating that it is an unusual surface protein. (32 refs)

- 79-6404** Lack of Correlation of Onset of Lymphomas and Levels of Murine Leukaemia Virus in (AKR x CBA/H-T6Crc) F1. (Eng) Barnes, R. D. (Dept. Embryology and Foetal Development, Clinical Res. Centre, Watford Rd., Harrow, Middlesex, England); Tuffrey, M.; Simpson, M. *Eur J Cancer* 15(8): 1043-1049; 1979.

The onset of lymphoma development in (AKR x CBA/H-T6Crc)F1 hybrid mice was correlated with the levels of murine leukemia virus (MuLV) in these animals. Compared with the parental AKR mice, lymphoma development was delayed in reciprocal AKR x CBA crosses. The levels of p30 were considerably lower in CBA controls than in macroscopically normal AKR controls and were significantly higher in the (CBA x AKR)F1 hybrids than in the AKR parents ($p < 0.05$). No antibody activity against AKR virus was demonstrated in any of 75 individual serum samples obtained from (AKR x CBA)F1 mice, suggesting the absence of "free" anti-AKR MuLV activity in the F1 hybrids up to 1 yr of age. The data indicate that lymphoma susceptibility is not invariably linked to the viral load in AKR-derived hybrids. (21 refs)

- 79-6405** H-2-Dependent Regulation of the High Level of Expression of Ecotropic Murine Leukemia Virus. (Eng) Colombatti, A. (Dept. Pharmacology and Experimental Therapeutics, Johns Hopkins Univ., 725 N. Wolfe St., Baltimore, MD 21205); Dux, A.; Berns, A.; Demant, P.; Hilgers, J. *J Natl Cancer Inst* 63(3): 869-873; 1979.

Ecotropic virus expression was examined in an H-2 congenic mouse strain on a B10 background. Adult B10.Y mice, which are congenic with C57BL/10ScSn (B10) mice for the H-2 region, expressed a high titer of infectious ecotropic virus in the spleen. B10 mice uniformly lacked detectable virus expression in the XC plaque assay or by immunofluorescence. F₁ hybrids between B10.Y and B10 mice were negative or had very low levels of virus expression. Among (B10.Y x B10)F₂ segregant mice, 11/17 virus-positive mice were H-2^{pa/pa} homozygous and 6, H-2^{pa/b} heterozygous. None of the H-2^{b/b} mice had detectable virus levels. This demonstrates that B10.Y mice possess a recessive gene within or close to the H-2 complex for the high-grade virus expression and that the H-2^b haplotype prevents the spontaneous expression of ecotropic virus in this hybrid. Molecular hybridization experiments with a selected ecotropic AK/R murine leukemia virus cyclic DNA probe indicated that both parental strains possessed ecotropic virus sequences and that the number of sequences was the same in B10.Y and B10 mice. This finding excludes the possibility that the H-2-related effect might be due to the presence of additional viral structural genes without or close to the H-2 region of B10.Y mice. The results demonstrate that genes within the H-2 region regulate the expression of endogenous viral genomes. To date, the evidence indicates that the genetic effect that results in a high level of expression of ecotropic virus early in life is also responsible for the high incidence of lymphomas in the B10.Y strain. (29 refs)

79-6406 A Murine Teratocarcinoma Stem Cell Line Carries Suppressed Oncogenic Virus Genomes. (Eng) Huebner, K. (Wistar Inst. Anatomy and Biology, Philadelphia, PA 19104); Tsuchida, N.; Green, C.; Croce, C. M. *J Exp Med* 150(2): 392-405; 1979.

Stem cell lines and differentiated cell lines established from a murine strain 129 testicular teratocarcinoma (OTT6050) were characterized with regard to their interaction with murine leukemia virus (MuLV). The stem cell line, which was completely nonpermissive to productive infection by Moloney MuLV and consisted of 97% pluripotent stem cells, contained DNA copies of an RNA tumor virus that was indistinguishable from the N-tropic MuLV of AKR mice. The stem cells were negative for the expression of viral reverse transcriptase (RT), p30, and gp69/71, and no virus was found by the XC plaque assay or other biological tests. Differentiated cells established from the same tumor were 100% positive for viral gp69/71 and p30, and they produced large amounts of RT activity and N-tropic virus. The virus isolated from these cells was closely related, if not identical, to AKR N-tropic virus and, thus, was not an endogenous virus of strain 129 mice. The teratocarcinoma tumor from which these lines were established had been carried in strain 129 mice, and perhaps at some time in the passage history, the tumors were nonproductively infected with the N-tropic virus. The OTT6050-derived stem and differentiated cell lines should be useful in defining in stem cells the step at which ecotropic MuLV replication is blocked. (42 refs)

79-6407 The Spleen Focus-forming Virus (SFFV)-specific Neoantigen Shares Cross-reactive Determinants with Mink Cell Focus-inducing (MCF) Virus gp70. (Eng) Gillis, S. (Hematology Res. Lab., Dept. Medicine, Dartmouth-Hitchcock Medical Center, Hanover, NH 03755); Ruscetti, S. K.; Gillis, A. E.; Troxler, D. H.; Scolnick, E. M.; Smith, K. A. *Virology* 96(2): 421-428; 1979.

An attempt was made to determine whether the spleen focus-forming virus (SFFV)-specific neoantigen, as defined by in vitro

cytolysis, shared determinants with antigens coded for by mink cell focus (MCF)-inducing viruses, which, like SFFV, are also xenotropic/ecotropic recombinants. As detected by direct cytolysis of SFFV- and MCF-infected target cells, the SFFV-specific neoantigen was partially cross-reactive with determinants on the surface of MCF virus-infected cells. The cross-reactive determinants appeared to be coded for by the envelope region of both AKR and Moloney MCF viruses, in that antisera specific for MCF gp70 were capable of blocking SFFV-specific neoantigen-directed cytolysis. These results provide further evidence in support of the recombinant nature of the SFFV genome and its close relationship to MCF viral genetic information. However, in that the SFFV-specific neoantigen was not totally cross-reactive with MCF gp70, it is possible that additional antigenic determinants associated with SFFV-encoded transformation may be present. (13 refs)

79-6408 Spontaneous Regression of Friend Murine Leukemia Virus-induced Erythroleukemia. IV. Effects of Radiation and Athymia on Leukemia Regression in Mice. (Eng) Furmanski, P. (Dept. Biology, Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI 48201); Dietz, M.; Fouche, S.; Hall, L.; Clymer, R.; Rich, M. A. *J Natl Cancer Inst* 63(2): 449-454; 1979.

A study was made of the effects of immunosuppressive procedures (ie, x-radiation, congenital athymia, and ⁹⁰Sr irradiation of the bone marrow) on leukemia regression in mice. The spontaneous regression of the erythroleukemia (EL) induced by the regressing Friend murine leukemia virus (F-MuLV) complex was inhibited by irradiation of the animals prior to F-MuLV inoculation. This inhibition was proportional to the radiation dose used. Treatment of the mice with the bone-seeking isotope ⁹⁰Sr also inhibited EL regression, which implicates the same effector mechanisms involved in the resistance to F-MuLV- or F-MuLV-induced immunosuppression. EL's induced in athymic nude mice by the regressing F-MuLV complex exhibited higher rates of lethality than did the leukemias in heterozygous or homozygous thymus gland-containing controls. These data suggest the involvement of the immune system in EL regression and the specific participation of thymus cells and an ⁹⁰Sr-susceptible function, perhaps marrow-dependent cells, in the process of regression. (29 refs)

79-6409 Virus Expression in Various Tissues of Mice Inoculated With Variants of Gross Leukemia Virus. (Eng) Santillana, M. (Tissue Culture and Virus Lab., E.R. No. 38, C.N.R.S., Quai Anatole-France, Paris 7e, France); Chiric, E.; Youn, J. K. *Eur J Cancer* 15(7): 953-963; 1979.

An in vitro XC coculture technique and electron microscopy were used to study the evolution of virus expression in various lymphoid tissues of C3H/Fe mice inoculated with two variants of tissue culture-adapted Gross passage A virus. When neonates were inoculated with a highly leukemogenic variant (TGV virus), three phases of virus expression could be distinguished during the latent period (av, 2 mo). In the early phase (first 3 wk after virus inoculation) as well as in the later phase (after day 50), there were abundant levels of virus in the bone marrow and spleen, moderate levels in the thymus, and slight levels or no virus in the lymph nodes and kidneys. In the intermediate phase (days 20-50), the virus disappeared completely or decreased significantly in all tissues tested. When neonates were inoculated with a nonleukemogenic variant (N1 virus), no virus could be detected in all tissues examined during the 2-mo period after virus inoculation. The virus recovered

from in vitro explanted and cultured kidney cells taken from mice inoculated with TGV virus induced typical Gross-type lymphoid leukemia in all C3HeB/Fe mice inoculated as newborns. However, the in vitro cellular tropism of this virus was B-tropic, but that of the original TGV virus was N-tropic. Frequent differentiation to heterologous tissues was observed electron microscopically in the thymuses of mice inoculated with TGV virus. (18 refs)

- 79-6410** Molecular Cloning of the Harvey Sarcoma Virus Closed Circular DNA Intermediates: Initial Structural and Biological Characterization. (Eng) Hager, G. L. (Tumor Virus Genetics Branch, NCI, Bethesda, MD 20205); Chang, E. H.; Chan, H. W.; Garon, C. F.; Israel, M. A.; Martin, M. A.; Scolnick, E. M.; Lowy, D. R. *J Virol* 31(3): 795-809; 1979.

The circular forms of Harvey sarcoma virus (HaSV) DNA inserted in the λ gtWES.1B vector and cloned in an approved EK2 host were characterized by restriction endonuclease digestion, molecular hybridization, electron microscopy, and infectivity. Four of the six HaSV DNA inserts were identical, containing about 6.0 kilobase pairs (kbp) and comigrating in agarose gels with the infectious, unintegrated, linear HaSV DNA. One insert was approx 0.65 kbp smaller and one was approx 0.65 kbp larger than these four inserts. R-looping with HaSV RNA revealed that the smallest insert contained one copy of the HaSV RNA. Preliminary restriction endonuclease digestion of the recombinant DNAs suggested that the middle-sized inserts contained a 0.65-kbp duplication of sequences present only once in the smallest insert. This duplication corresponded to the 0.65-kbp terminal duplication of the unintegrated linear HaSV DNA. The largest insert apparently contained a tandem triplication of these terminally located sequences. DNA of all three sized inserts induced foci in NIH 3T3 cells, and focus-forming activity could be rescued from the transformed cells by superinfection with helper virus. Infectivity followed single-hit kinetics, suggesting that the foci were induced by a single molecule. (42 refs)

- 79-6411** Identification of a Sarcoma Virus-coded Phosphoprotein in Nonproducer Cells Transformed by Kirsten or Harvey Murine Sarcoma Virus. (Eng) Shih, T. Y. (Lab. Tumor Virus Genetics, NCI, NIH, Bethesda, MD 20205); Weeks, M. O.; Young, H. A.; Scolnick, E. M. *Virology* 96(1): 64-79; 1979.

A 21,000-dalton protein (p21) coded for by Harvey or Kirsten murine sarcoma virus (Ha- or Ki-MuSV) was identified in non-producer cells transformed by these two viruses. Antisera prepared from rats bearing tumors induced by syngeneic transplantation of normal rat kidney cells transformed by Ha-MuSV specifically precipitated the Ha-MuSV p21 from a nonproducer BALB/c mouse cell and a nonproducer dog cell transformed by Ha-MuSV. The same antisera also precipitated a similar protein, Ki-MuSV p21, from a nonproducer mink cell transformed by Ki-MuSV. Both p21's were phosphoproteins. Previous studies have reported the production of a virus-specific p21 polypeptide from the translation of Ha-MuSV RNA in cell-free protein synthesis systems. This p21 protein was specifically precipitated by the same antitumor sera. Similarly, a p21 polypeptide translated from Ki-MuSV RNA was also specifically precipitated by the antitumor sera. Therefore, it is concluded that the p21 of Ha-MuSV and Ki-MuSV are homologous proteins coded for by homologous sequences found in the recombinant genomes of Ha-MuSV and Ki-MuSV. (31 refs)

- 79-6412** Inhibition of Spontaneous Transformation of Rat Embryo Cells Releasing Endogenous Type C Virus by Virus-Specific Antiserum. (Eng) Rasheed, S. (Dept. Pathology, Univ. Southern California Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA 90033); Young, H.; Gardner, M. B. *J Natl Cancer Inst* 63(3): 745-750; 1979.

Three clonal Sprague-Dawley (SD-1) cell lines, each releasing endogenous rat leukemia virus (RaLV), were treated with RaLV-specific antiserum (1:250 dilution) for 3, 7, or 15 days. Following this treatment, transformation was delayed 6-28 wk after control SD cultures had transformed. Transformation of SD-1 cell clones in the absence of RaLV antiserum was a highly reproducible and predictable event. Treatment with RaLV-specific antiserum also reduced virus production and infectivity. Transformation in the SD-1 cell system was not correlated with increasing levels of Kirsten murine sarcoma virus-related *src* RNA because similar amounts of these transcripts were detected in both transformed and nontransformed (RaLV-antiserum-treated) cell clones. However, the non-transformed SD-1 cells contained 10-fold lower levels of RaLV-related RNA than did the transformed cells. These results indicate that a minimum threshold of infectious virus expression is required for transformation to occur. (18 refs)

- 79-6413** Moloney Murine Sarcoma Virions Synthesize Full-Genome-Length Double-stranded DNA In Vitro. (Eng) Benz, E. W. (Dept. Developmental Biology and Cancer, Albert Einstein Coll. Medicine, Bronx, NY 10461); Dina, D. *Proc Natl Acad Sci USA* 76(7): 3294-3298; 1979.

The in vitro synthesis of full-length viral double-stranded DNA by moloney murine sarcoma virus (MSV) virions disrupted by Triton X-100 is described. The major product, a 5,950-base pair (6-kilobase pair DNA) double-stranded DNA, was characterized by cleavage with restriction endonucleases and shown to contain a 600-nucleotide-long direct repeat at both ends of the MSV genome. Linear DNA molecules made in vivo shortly after infection were compared with the linear double-stranded DNA synthesized in vitro. The restriction maps of both viral DNA products were indistinguishable. The 600-base pair repeat resulted in a progeny DNA molecule that was longer than the parental MSV genomic RNA. The generation of this repeat must involve a mechanism that allows the viral reverse transcriptase (RNA-dependent DNA nucleotidyltransferase) to copy 5'- and 3'-terminal genomic (+) strand sequences twice. (27 refs)

- 79-6414** Heat-labile Character of Murine Sarcoma-Xenotropic Leukemia Virus Complex in Duck Cells. (Eng) Hirai, R. (Tokyo Metropolitan Inst. Medical Science, Honkomagome, Bunkyo-ku, Tokyo 113, Japan); Yuasa, Y.; Yamamoto, T. *Virology* 96(2): 615-621; 1979.

The infection of duck embryo (DE) cells with the xenotropic murine leukemia virus (X-MuLV) pseudotype of wild-type Moloney murine sarcoma virus (MSV) was investigated. The MSV(X-MuLV) complex induced foci and replicated in DE cells at 37 C. Both Japanese quail and chick embryo cells were resistant to infection with MSV(X-MuLV). At 41 C, the number of foci induced by MSV(X-MuLV) in DE cells was one-hundredth that induced at 37 C. In contrast, avian sarcoma virus (ASV) subgroup C transformed DE cells with almost equal efficiency at 37 and 41 C. The temperature-sensitive step of MSV(X-MuLV) resided in the early phase of infection (within 24 hr postinfection). MSV(X-

MuLV) virions were more heat-labile than ASV virions and phenotypically mixed ASV virions with X-MuLV properties. The virion-associated reverse transcriptase activity of X-MuLV was rapidly inactivated at 41 C, but the enzyme activity of ASV was stable at 41 C. The results suggest that the reduction of infectivity of MSV(X-MuLV) in DE cells at 41 C is due to the heat-labile character of the reverse transcriptase of X-MuLV. (26 refs)

- 79-6415 Heteroduplex Analysis of the Sequence Relationships Between the Genomes of Kirsten and Harvey Sarcoma Viruses, Their Respective Parental Murine Leukemia Viruses, and the Rat Endogenous 30S RNA. (Eng) Chien, Y. H. (Dept. Chemistry and Chemical Engineering, California Inst. Technology, Pasadena, CA 91125); Lai, M.; Shih, T. Y.; Verma, I. M.; Scolnick, E. M.; Roy-Burman, P.; Davidson, N. *J Virol* 31(3): 752-760; 1979.

The sequence relationships between Kirsten murine sarcoma virus (Ki-SV), Harvey murine sarcoma virus (Ha-SV), and a rat endogenous 30S RNA were studied by electron microscope heteroduplex analysis, as were the sequence relationships between the sarcoma viruses and their respective parental murine leukemia viruses (Kirsten and Moloney murine leukemia viruses) and between the two murine leukemia viruses themselves. The only observed nonhomology feature of the Kirsten murine leukemia virus/Moloney murine leukemia virus heteroduplexes was a substitution loop with two arms of equal length extending from 1.80 ± 0.18 kilobases (kb) to 2.65 ± 0.27 kb from the 3' end of the RNA. It is believed that this feature lies in the *env* gene region of the viral genomes. The Ha-SV and Moloney murine leukemia virus genomes (respective lengths, 6.0 and 9.0 kb) were homologous only in a 1.0 ± 0.05 -kb region at the 3' end and possibly over a 200-nucleotide region at the 5' ends. Ha-SV and Ki-SV (length, 7.5 kb) were homologous in the first 4.36 ± 0.37 -kb region from the 3' end and in a 0.70 ± 0.15 -kb-region at the 5' end. In between, there was a generally nonhomologous region, possibly containing a short (0.23-kb) region of partial or total homology. Rat endogenous 30S RNA and Ki-SV showed mixed regions of sequence homology and nonhomology at both the 5' and 3' ends. However, there was a large (4-kb) region of homology between Ki-SV and the rat 30S RNA in the center of the genomes, with only a small nonhomologous hairpin feature. The regions of homology between the Ha-SV and Ki-SV genomes and between these viruses and the rat endogenous 30S RNA may be related to the oncogenicity of the viruses. In particular, the 0.7-kb region of homology of Ha-SV with Ki-SV at the 5' ends may be related to the formation of a 21,000-dalton phosphoprotein in cells transformed by either virus. (20 refs)

- 79-6416 Mutant of B-Tropic Murine Leukemia Virus Synthesizing an Altered Polymerase Molecule. (Eng) Gerwin, B. I. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD 20205); Rein, A.; Levin, J. G.; Bassin, R. H.; Benjers, B. M.; Kashmiri, S. V.; Hopkins, D.; O'Neill, B. J. *J Virol* 31(3): 741-751; 1979.

A nonconditional mutant of B-tropic murine leukemia virus (MuLV), defective in polymerase, was isolated by cloning chronically infected cells. The mutant-containing clone produced virus particles which were noninfectious. However, superinfection of the cells by replication-competent XC-negative viruses resulted in the rescue of virus capable of forming plaques in a modified XC test, termed the "complementation plaque assay". Analysis of the

noninfectious virions produced without superinfection demonstrated that they contained only 2 to 5% of the wild-type level of reverse transcriptase activity. Purification of this activity indicated that it was associated with a smaller molecule than that produced by wild-type virus. Cells producing the mutant virions did not contain the *gag-pol* precursor Pr180-^{gag-pol}, but did contain proteins of 147K and 114K daltons precipitable with anti-*pol* serum. All of the normal structural proteins as well as 70S genomic RNA could be detected in the mutant particles. An interference test indicated that a functional ecotropic glycoprotein was synthesized by the mutant. These results indicate that the mutant has a unique defect in the *pol* gene. (43 refs)

- 79-6417 Studies on the DNA of an Oncogenic Papovavirus of the Syrian Hamster. (Eng) Scherneck, S. (Dept. Bioregulation, Central Inst. Molecular Biology, 1115 Berlin-Buch, E. Germany); Bottger, M.; Feunteun, J. *Virology* 96(1): 100-107; 1979.

The DNA of Syrian hamster papovavirus (HaPV) was characterized by physicochemical methods and by digestion with site-specific restriction endonucleases. The HaPV isolated from multiple skin tumors of Syrian hamsters contained supercoiled, double-stranded DNA with a guanine/cytosine content of 39.2% and a mol wt that was within the range of that of simian virus 40 (SV 40) and polyoma virus DNA. Spectrophotometric melting and annealing curves indicated a high thermal stability and a high sequence homogeneity of the HaPV DNA. Cleavage of the DNA with restriction endonucleases *Bam*H1, *Hind*II, and *Eco*RI produced one, three, and four fragments, respectively, and the electrophoretic pattern of the products of digestion was distinctly different from that of SV40 and all other known papovaviruses. The relative positions of the *Bam*H1, *Hind*II, and *Eco*RI restriction endonuclease sites were established, taking the unique *Bam*H1 site as a zero point. (17 refs)

- 79-6418 Replication of Vesicular Stomatitis Virus Facilitated by Shope Fibroma Virus In Vivo. (Eng) Crouch, N. A. (Dept. Biomedical Sciences, Rockford Sch. Medicine, Univ. Illinois Coll. Medicine, Rockford, IL 61101); Mitchell, R. L. *Infect Immun* 25(1): 213-219; 1979.

The possibility that Shope fibroma virus and vesicular stomatitis virus (VSV) can interact in vivo was examined. Rabbits inoculated id with both viruses together, or each separately, were examined for the formation of lesions or tumors and for the production of infectious virus. The presence of VSV interfered with tumorigenesis by Shope fibroma virus. Production of infectious VSV was greater in the tumors that formed than in normal skin. Hence, each virus affected the other. Sera and tissues of normal rabbits contained a substance that inhibited VSV; this substance may act to limit replication of VSV in rabbit skin. In addition, cultured rabbit skin cells appeared to adsorb VSV inefficiently. When persistently infected by Shope fibroma virus, however, adsorption of VSV was markedly improved. The results suggest that, in vivo, Shope fibroma virus may facilitate the adsorption of VSV to reduce the effect of a natural inhibitor and, consequently, enhance the production of infectious virus. (10 refs)

- 79-6419 Pathogenesis of Experimental Feline Leukemia Virus Infection. (Eng) Rojko, J. L. (Dept. Veterinary

Pathobiology, Ohio State Univ., 1925 Coffey Rd., Columbus, OH 43210; Hoover, E. A.; Mathes, L. E.; Olsen, R. G.; Schaller, J. P. *J Natl Cancer Inst* 63(3): 759-768; 1979.

Early events in the pathogenesis of feline leukemia virus (FeLV) infection were studied in 59 specific-pathogen-free cats. Young cats (≤ 8 wk old and highly susceptible to FeLV) and adult cats (> 6 mo old and relatively resistant to FeLV) were exposed to FeLV by oral-nasal, ip, or sc inoculation. The sequential distribution of FeLV group-specific antigen (GSA) in blood and tissues of susceptible vs resistant cats was correlated with alterations in hematologic and serologic parameters. Six sequential phases of FeLV infection (ie, viral replication) were identified: (1) lymphoreticular cells in local lymphoid tissues [2-4 days after exposure (DAE)]; (2) circulating lymphocytes and monocytes (early cell-associated viremia; 1-14 DAE); (3) lymphoid germinal cells in lymphoid tissues throughout the body (3-12 DAE); (4) bone marrow neutrophil and platelet precursor cells and intestinal crypt epithelium (7-21 DAE); (5) circulating neutrophils and platelets (with establishment of viremia) (≥ 14 -28 DAE); and (6) mucosal and glandular epithelial tissues (with excretion of FeLV; ≥ 28 -56 DAE). Early lymphoreticular virus replication (phases 1-3) was present in both progressive and transient infection. In cats that became persistently infected (80% of young cats and 14% of adult cats), FeLV infection was not contained in the initial lymphoreticular phases 1-3, and extensive virus replication occurred in the germinal cell populations of lymphoid, hematopoietic, and epithelial tissues (phases 3-6). In cats with progressive infections, lymphopenia and neutropenia (21-56 DAE) were associated with the appearance of FeLV GSA in circulating neutrophils and platelets (≥ 14 -28 DAE). In cats with self-limiting infections, virus containment in phases 3 or 4 correlated with transient lymphopenia (7-14 DAE) and development of antibody to the feline oncornavirus-associated cell membrane antigen. 79-6420 Partial Characterization of a New Type of Bovine Papilloma Viruses. (Eng) Pfister, H. (Institut für Virologie, Zentrum für Hygiene, Universität Freiburg, Hermann-Herder-Strasse 11, 7800 Freiburg, W. Germany); Linz, U.; Gissmann, L.; Huchthausen, B.; Hoffmann, D.; zur Hausen, H. *Virology* 96(1): 1-8; 1979.

Bovine papilloma virus (BPV) isolates from 13 individual bovine cutaneous warts were characterized by monospecific rabbit antisera. They fell into two groups without detectable crossreactivity when tested by immune electron microscopy or complement fixation. Complementary RNA transcribed from representatives of both groups did not hybridize with DNA from heterologous isolates. The two types of BPV also differed in the electrophoretic mobility of their proteins and in the mol wt of their DNA (4.5×10^6 and 4.9×10^6 daltons, respectively). One isolate with a DNA of 4.9×10^6 daltons and one isolate with a DNA of 4.5×10^6 daltons were analyzed by cleavage of their DNA with the restriction endonucleases *Bam*HI, *Eco*RI, *Hind*II, *Hind*III, and *Hae*III, and physical maps were established. The two genomes differed completely in their cleavage pattern. The *Hind*II cleavage pattern demonstrated the identity of the large DNA isolate with BPV type 2, which was recently characterized by restriction endonuclease cleavage and kinetic nucleic acid hybridization. The other apparently new type of BPV, which has been detected twice thus far, is tentatively designated as BPV type 3. (22 refs)

79-6421 The *Bevi* Locus (Chromosome 6) Encodes a Post-penetrational Cellular Function Required for Baboon Endogenous Virus Replication in Human Cells. (Eng) Lemons, R.

S. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD); O'Brien, S. J.; Sherr, C. J. *Cytogenet Cell Genet* 22(1-6): 255-259; 1978.

The genetic characteristics of a chromosome (CS) locus (*Bevi*, for baboon endogenous virus infection) on human CS 6 that positively controls baboon virus replication were studied. M7 baboon virus-infected hybrid cells were obtained by the fusion of mouse A1-2 cells (HPRT-) with six fresh human bone marrow specimens and WI38 fibroblasts and of Chinese hamster E36 cells (HPRT-) with two of the bone marrow specimens. Virus was detected in permissive cells within 3 wk after infection. Biological and immunological tests confirmed that it was distinct from murine leukemia virus (MuLV) and indistinguishable from M7. The host range of the recovered virus was identical to that of baboon endogenous virus, and group-specific anti-p30 sera yielded radioimmune precipitation curves identical to those for M7 p30 and distinct from those for Rauscher MuLV p30. Of 194 hybrid clones examined, 97% showed concordance between M7 replication and human CS 6; 39% were discordant with CS 19. These data exclude the specific participation of genes on CS 19 in baboon virus replication in human x rodent hybrids. In additional studies, human vA-2 cells (HPRT-) were infected with M7, cloned, and fused to Syrian hamster BHK-B1 cells (TK-). Again, a high concordance between human CS 6 and continued viral expression was demonstrated. Since the human parent was productively infected with M7 prior to fusion, the concordance of virus production, p30 synthesis, and CS 6 markers demonstrates that the *Bevi* locus function is subsequent to virus penetration but prior to viral protein synthesis. Preliminary molecular hybridization experiments showed that *Bevi* is the preferred integration site of baboon C-type DNA provirus in the human genome. (9 refs)

79-6422 Assignment of a Gene Required for Infection with Endogenous Baboon Virus to Human Chromosome 19. (Eng) Brown, S. (NCI-VA Oncology Branch, VA Hosp., Washington, DC); Oie, H.; Francke, U.; Gazdar, A. F.; Minna, J. D. *Cytogenet Cell Genet* 22(1-6): 239-242; 1978.

A parasexual approach using 29 independent primary human x hamster hybrid clones segregating human chromosomes was used to identify human genes required to support the replication of M7 baboon virus. Fresh human bone marrow cells from two sources were fused with Chinese hamster E36 cells, and clones were tested for susceptibility to M7 virus by a specific fluorescent antibody test that detects viral p30 protein in fixed cell preparations and by a reverse transcriptase assay. Using a modified Giemsa-trypsin banding technique, human and hamster chromosomes were identified in eight primary clones. Chromosomes 15 and 19 correlated most closely with virus replication. Each chromosome had only one discordant clone out of eight clones tested. The exceptional clone, which was virus-replication-positive without a recognizable chromosome 19, contained small fragments possibly derived from a 19. Three clones with intact chromosome 6's were unable to support infection, but one clone that supported infection had no recognizable chromosome 6. Enzyme and chromosome analyses revealed that human chromosome 19 was required for viral infection. It is not known whether the inconsistent results found with chromosome 6 represent human polymorphism or whether they indicate the existence of several genes for integration or receptor sites. (10 refs)

79-6423 Structural Analysis of the Genomes of Gibbon Ape and Woolly Monkey Leukosis Viruses. (Eng)

Sahagan, B. G. (Sidney Farber Cancer Inst., Boston, MA 02115); Haseltine, W. A. *J Virol* 31(3): 657-667; 1979.

The RNAs of gibbon ape and woolly monkey leukemia viruses were compared by two-dimensional polyacrylamide gel electrophoresis of the large RNase T1-resistant oligonucleotides. Polyadenylic acid-containing 70S genomic RNA was isolated from purified virions and fingerprinted. The fingerprints of two gibbon ape viruses (GaLV-H and GaLV-Br) were very similar, the majority of the oligonucleotides of these two viruses having the same electrophoretic mobility. Electrophoresis of 14 pairs of RNase T1-resistant oligonucleotides indicated that most such oligonucleotides that comigrated probably had the same sequences. The other viruses studied (simian sarcoma-associated virus, gibbon ape leukemia virus-Thailand, and gibbon ape leukemia virus-San Francisco) showed an extensive but somewhat lower degree of sequence identity (between 40% and 60% of the genomes). (28 refs)

79-6424 Establishment of a Lymphoblastoid Cell Line and Isolation of an Epstein-Barr-related Virus of Gorilla Origin. (Eng) Neubauer, R. H. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21701); Rabin, H.; Strnad, B. C.; Nonoyama, M.; Nelson-Rees, W. A. *J Virol* 31(3): 845-848; 1979.

An antigenically unique virus (Herpesvirus gorilla, HVG) isolated from cultured mononuclear cells (Machi cells) of the peripheral blood of a female gorilla (*Gorilla gorilla*) was characterized. The Machi cells contained surface IgG and released IgG, were positive for Fc receptors and negative for sheep RBC receptors, and were therefore considered to be of B-cell origin. Approx 1%-2% of the cells were positive for antibodies related to Epstein-Barr virus (EBV). The early antigen of EBV and HVG differed in some respects, however, as did the nuclear antigen of HVG, Herpesvirus papio, and EBV. HVG DNA hybridized 30%-40% to EBV DNA and was present in Machi cells at approx 40-50 genome copies/cell. Cells from two gibbons inoculated with Machi culture fluids showed signs of transformation within 14 days and gave rise to two lymphoid cell lines. Machi cells also showed a low level of positivity for type C RNA virus. (18 refs)

79-6425 Methylation of *Herpesvirus saimiri* DNA in Lymphoid Tumor Cell Lines. (Eng) Desrosiers, R. C. (New England Regional Res. Center, Harvard Medical Sch., One Pine Hill Drive, Southborough, MA 01772); Mulder, C.; Fleckenstein, B. *Proc Natl Acad Sci USA* 76(8): 3839-3843; 1979.

Several continuous lymphoid cell lines have been established from tumors induced by *Herpesvirus saimiri*. At least a portion of the viral DNA in the marmoset lymphoid cell line 1670, which does not produce detectable virus, is present as covalently closed circular episomal DNA. The use of restriction endonuclease digestion, transfer to nitrocellulose filters, and hybridization of the virus-specific DNA produced strong evidence that viral DNA sequences present in total 1670 cell DNA and in isolated episomes are extensively methylated. The restriction endonuclease *Hpa* II has the same recognition sequence as *Msp* I but, unlike *Msp* I, failed to cleave when the C of the C-G dinucleotide was methylated. Viral DNA sequences of 1670 cells were refractory to cleavage by *Hpa* II but not *Msp* I; greater than 80% of the *Hpa* II cleavage sites appeared to be methylated. Similarly, viral DNA sequences of 1670 cells were refractory to cleavage by *Sma* I (C-C-C-G-G-G)

and *Sac* II (C-C-G-C-C-G) but not *Sac* I, *Pvu* II, or *Pst* I, which lacked the dinucleotide C-G in their recognition sequences. Methylation of mammalian DNA has been previously found exclusively at C residues in the dinucleotide C-G. *H. saimiri* DNA sequences of another nonproducer cell line, 70N2, also appeared to be extensively methylated, but analysis of total cell DNA extracted from three virus-producing lymphoid lines revealed no evidence of methylation of viral DNA sequences. It remains to be seen if methylation of viral DNA plays a role in the lack of complete expression of *H. saimiri* genome information in nonproducing lymphoid cell lines. (22 refs)

79-6426 Association of Herpes Simplex Virus (HSV) with Cervical Cancer by Lymphocyte Reactivity with HSV-1 and HSV-2 Antigens. (Eng) Smith, J. W. (Dept. Microbiology, Louisiana State Univ. Medical Center, 1542 Tulane Ave., New Orleans, LA 70112); Torres, J. E.; Holmquist, N. D. *Am J Epidemiol* 110(2): 141-147; 1979.

Procedures for distinguishing subjects with previous herpes simplex virus (HSV)-1 and -2 infections by means of differences in lymphocyte reactivity to HSV-1 and HSV-2 antigens were developed and applied to the detection of past HSV-2 infection in 26 patients with invasive epidermoid cervical carcinoma and 26 controls matched for age, race, and socioeconomic class. In addition, lymphocyte blastogenesis (³H-thymidine uptake after 6 days incubation) induced by HSV-1 and HSV-2 antigens in persons with histories of HSV infection (11 with HSV-1, 11 with HSV-2, 16 with HSV-1 and -2, and 6 seronegative controls) was determined; lymphocytes from subjects with previous HSV-1 or HSV-2 infection had higher blastogenic responses to homologous virus antigen than to heterologous antigen. When the responses to HSV-2 were divided by the responses to HSV-1, the group with HSV-1 infection was significantly different from the HSV-2 group ($p < 0.005$), yielding a mean value of 28 compared with 132 from the HSV-2 group. Those exposed to both viruses had a value intermediate between those of the HSV-1 and HSV-2 groups. Lymphocyte populations from subjects seropositive for HSV were cross-reactive in all cases. These data suggest that the characteristic of cross-reactivity with antisera to HSV-1 and HSV-2 also occurs with cellular immune responses to viral antigens. Blood specimens were obtained from cancer patients prior to radiation therapy and separated into subpopulations by Ficoll-Hypaque centrifugation. Lymphocytes were cultured with autologous plasma and exposed to phytohemagglutinin (PHA), HSV-1, HSV-2, and control antigens. Stimulation ratios for blastogenic responses to HSV antigens and PHA were higher in cancer patients than controls. When blastogenic responses in the groups with known HSV infection were used to define ranges of HSV-2/HSV-1 ratios suggestive of previous HSV-2 infection in the cancer patients, up to 88% of cancer patients were found to have suffered previous HSV-2 infection, whereas <50% of controls had evidence of cellular immunity to HSV-2 ($p < 0.005$). When the same criteria were applied to analyses of lymphocytes from subjects who had had previous infection with both HSV-1 and HSV-2, past infection with HSV-2 was not detected in all cases, suggesting that dual infection may modify the blastogenic response to a degree sufficient to mask evidence of immunity to HSV-2. (16 refs)

79-6427 Regulation of Persistent Infection with Herpes Simplex Virus In Vitro by Hydrocortisone. (Eng) Nishiyama, Y. (Dept. Microbiology and Specialized Cancer Res. Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA 17033); Rapp, F. *J Virol* 31(3): 841-844; 1979.

About 1% of Raji cells showed sensitivity to herpes simplex virus type 2 (HSV-2) infection when tested by infectious center assays or immunofluorescence tests, and the percentage did not change during cell passage. The addition of hydrocortisone to Raji cells persistently infected with HSV-2 caused a marked increase in virus production and in the number of HSV-producing cells. In the case of HSV-1, the addition of hydrocortisone was required to maintain persistent infection. These observations suggest that control of replication of HSV-1 and HSV-2 in these cells is regulated by different mechanisms. (12 refs)

- 79-6428 Biological and Biochemical Observations on Isolates of EB Virus from the Malignant Epithelial Cells of Two Nasopharyngeal Carcinomas. (Eng) Crawford, D. H. (Dept. Pathology, Univ. Bristol Medical Sch., Univ. Walk, Bristol BS8 1TD, England); Epstein, M. A.; Bornkamm, G. W.; Achong, B. G.; Finerty, S.; Thompson, J. L. *Int J Cancer* 24(3): 294-302; 1979.

The behavior and biochemical nature of Epstein-Barr (EB) virus isolated from tumors of two separate nasopharyngeal carcinomas passaged in nude mice (NPC) were investigated. Fetal mononuclear cells infected with cyst fluid from nude-mouse-grown NPC proliferated into a cell line after 20 days in culture. Adult seronegative mononuclear cells also produced a cell line (J-ABA) after 40 days in coculture with nude-mouse-grown NPC fragments. Marmoset mononuclear cells cocultivated with x-irradiated J-ABA cells grew into a cell line after 47 days. Chromosome analysis indicated that the target cells had been transformed in each case, and immunofluorescence showed that each line contained >90% EB nuclear antigen (NA)-positive cells. The lymphoblastoid nature of all the cell lines was confirmed by light and electron microscopy. The fetal-derived lines did not produce virus spontaneously, could not be activated with various inducers, and carried only small numbers of genome copies per cell. Electron microscopy showed that the J-ABA and the marmoset lines produced C-type retrovirus particles and could be induced to produce more virus by treatment with 5-iododeoxyuridine or 12-O-tetradecanoylphorbol-13-acetate. These findings demonstrate that the incidence of productively infected cells in these lines is not determined by the intrinsic capabilities of the NPC-derived virus they carry but by the target cell from which the line originates. (52 refs)

- 79-6429 Production of Lymphoid Tumors in Hamsters by Direct Implantation of Human Umbilical Cord WBC. I. Production of Lymphoid Tumors and Their Culture and Serial Transplantation. (Jpn) Matsuda, Y. (Second Dept. Internal Medicine, Okayama Univ. Medical Sch., Okayama, Japan). *Acta Haematol Jpn* 42(3): 357-367; 1979.

Lymphoid tumors were produced in antilymphocyte serum-treated newborn Syrian hamsters that were given intraarterial transplants of human umbilical cord leukocytes (HCL) infected or noninfected with Epstein-Barr virus. Human lymphoblastoid cell lines were cultured from the lymphoid tumors and the tumors were transplanted serially. Lymphoid tumors were discovered by autopsy 10-27 days after administration of EBV-infected HCL in 25/25 hamsters and in 24/33 hamsters after administration of noninfected HCL. Histological examination showed lymphosarcoma-like lymph node enlargement and malignant cell infiltration of the organs. EBV-positive human lymphoblastoid cell lines were established from EBV-infected HCL-induced tumors, but not

from noninfected HCL-induced tumors. However, infection of the latter with EBV at culture initiation resulted in the establishment of EBV-positive human lymphoblastoid cell lines. These lines had a human diploid karyotype. The tumor cells were transplanted for two passages in newborn hamsters. The results indicate that EBV infection is not a prerequisite for the in vivo production of lymphoid tumors but that it is necessary for the in vitro establishment of lymphoblastoid cell lines from these tumors. The graft-vs-host reaction may have a role in the production of tumors in this experimental model. (24 refs)

- 79-6430 Epstein-Barr Virus DNA Is Amplified in Transformed Lymphocytes. (Eng) Sugden, B. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Phelps, M.; Domoradzki, J. *J Virol* 31(3): 590-595; 1979.

Leukocytes isolated from two adult donors who lacked detectable antibodies to Epstein-Barr virus-associated antigens were exposed to an av of 0.02 to 0.1 DNA-containing particles of Epstein-Barr virus per cell and immediately cloned in agarose. Within about 30 generations all transformed cell clones contained between 5 and 800 copies of viral DNA per cell. Only 1 in 10^4 to less than 1 in 10^5 of the cells of each clone released virus, and the frequency of release was not correlated with the av number of copies of viral DNA per cell. When one clone with an av of 5 copies of viral DNA per cell was recloned, the av number of copies in 4 of 6 subclones increased 15- to 50-fold while the subclones were being propagated sufficiently for study. These results indicate that Epstein-Barr virus DNA can undergo amplification relative to cell DNA at different times after it transforms cells. (18 refs)

- 79-6431 Analysis of Early and Late Epstein-Barr Virus Associated Polypeptides by Immunoprecipitation. (Eng) Mueller-Lantzsch, N. (Institut für Virologie, Zentrum für Hygiene der Universität Freiburg, Hermann-Herder-Strasse 11, D-7800 Freiburg, W. Germany); Yamamoto, N.; zur Hausen, H. *Virology* 97(2): 378-387; 1979.

The Epstein-Barr virus-producing cell lines P3HR-1 and B95-8 and the nonproducer cell lines Raji clone No. 7 and NC37 were induced to viral antigen synthesis by the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) and then analyzed by immunoprecipitation with human sera for early and late virus-associated polypeptides. After labeling of producer cells for a 4-day period with [35 S]methionine, two polypeptides with mol wt of 140,000 and 150,000 were identified, reacting predominantly with virus capsid antigen (VCA+) sera. Analysis of purified Epstein-Barr virus demonstrated that the 140,000 polypeptide presumably represents an envelope protein while the 150,000 polypeptide is a nucleocapsid protein. In 4-hr radioactively labeled producer cells, an additional polypeptide with a mol wt of 130,000 was immunoreactive with VCA+ sera. Immunoprecipitation of [35 S]methionine-labeled cell extracts from nonproducer cells resulted in the specific precipitation of two polypeptides (mol wt 85,000 and 35,000) which most likely represent early EBV-associated proteins. Producer cells exhibited three additional apparent early EBV-associated polypeptides (mol wt 120,000, 18,000 and 16,000). None of these polypeptides could be detected in EBV genome-negative Ramos cells after TPA treatment. (36 refs)

- 79-6432 Enhancement of Epstein-Barr Virus Replication in Producer Cell Lines by a Combination of Low

Temperature and Corticosteroids. (Eng) Magrath, I. T. (Section Infectious Disease, Pediatric Oncology Branch, NCI, Bldg. 10, Rm 2B-50, Bethesda, MD 20205); Pizzo, P. A.; Novikovs, L.; Levine, A. S. *Virology* 97(2): 477-481; 1979.

The effect of a combination of low temperature and corticosteroids on virus production was examined in three Epstein-Barr virus (EBV) producer cell lines. Mycoplasma-free P3HR1, B95-8, and AG-876 cells were cultured at 32 C in the presence or absence of either dexamethasone sodium phosphate or hydrocortisone sodium succinate in concentrations between 2.5×10^{-7} and 2.5×10^{-3} mM. EBV capsid antigen (VCA) was assayed by an immunofluorescent technique. Corticosteroid-stimulated P3HR1 cells grown at 32 C showed a marked increase in the fraction of cells expressing VCA (70%-90%) compared with that in unstimulated cultures (20%-35%), but this effect was very small at 37 C. Electron microscopy of P3HR1 cell pellets showed a comparable difference in the fraction of virus-containing cells at 32 C. The av number of virions per cell was increased up to 30-fold by steroids. This phenomenon was not seen in B95-8 or AG-876 cells. In DNA quantitation studies, a typical control culture yielded 0.33 $\mu\text{g/liter}$ of pure EBV DNA, while cultures optimally stimulated with corticosteroids yielded 3.2 $\mu\text{g/liter}$ of viral DNA. In another experiment, Raji cells were exposed for 1 hr at 37 C to P3HR1 culture supernatants and were examined at 48 hr by immunofluorescence for the appearance of early antigen. The results confirmed an increase in infectious virus in steroid-treated cultures. (33 refs)

79-6433 New Classes of Viable Deletion Mutants in the Early Region of Polyoma Virus. (Eng) Griffin, B. E. (Imperial Cancer Res. Fund, London WC2, England); Maddock, C. *J Virol* 31(3): 645-656; 1979.

Viable mutants of polyoma virus which have deletions in defined parts of the early region of the genome were isolated. One class of mutants has deletions (less than 1% of viral genome length) located between 71.5 and 73.5 on the physical map of polyoma virus DNA, near the origin of replication. These mutants appear to grow and to transform cells in a manner indistinguishable from wild-type virus. A second type of mutant with deletions (about 2% of viral genome length) located between about 88 and 94.5 units on the physical map of polyoma virus DNA have altered transformation properties. One of these (which maps between 88 and 91.5 units) also has altered growth characteristics, whereas another (which maps between 91.5 and 94.5 units) resembles wild-type virus in its growth properties. The regions with deleted sequences were defined by cleaving mutant DNAs with restriction endonucleases and analyzing pyrimidine tracts. (35 refs)

79-6434 Molecular Cloning of Polyoma Virus DNA in *Escherichia coli*: Oncogenicity Testing in Hamsters. (Eng) Israel, M. A. (Recombinant DNA Res. Unit, Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD 20205); Chan, H. W.; Martin, M. A.; Rowe, W. P. *Science* 205(4411): 1140-1142; 1979.

Inoculation of suckling hamsters with 2×10^8 live cells of *Escherichia coli* K12 strain χ 1776, carrying the complete genome of polyoma virus in a recombinant plasmid, failed to induce tumors in any of 32 recipients. Lambda phage DNA and particles with a monomeric insert of polyoma DNA also did not induce tumors. Purified recombinant plasmid DNA, as well as phage par-

ticles and DNA containing a head-to-tail dimer of polyoma DNA, showed a low degree of oncogenicity, comparable to that of polyoma DNA prepared from mouse cells. These findings support the previous conclusions, based on infectivity assays in mice, that propagation of polyoma virus DNA as a component of recombinant DNA molecules in *E. coli* reduces its biologic activity by many orders of magnitude relative to the virus itself. (10 refs)

79-6435 Cell Cycle Dependence of Transformation Expression in Mouse Cells Transformed by a Thermosensitive Mutant (Ts-121) of Polyoma Virus. (Eng) Okada, Y. S. (Natl. Inst. Radiological Sciences, Anagawa, Chiba 280, Japan); Hakura, A. *J Cell Physiol* 100(2): 263-272; 1979.

Changes in mitotic capability as a phenotypic expression of cellular transformation was investigated in 121-6-5 cells, a temperature-sensitive (ts) mutant of a polyoma virus-transformed BALB/3T3 cell line. Hyaluronidase treatment of contact-inhibited cells at 39 C induced a single round of cell division, which was then followed by inhibition of cell growth by cell density. However, when the cells were incubated at 35 C following enzyme treatment, the density-inhibition block disappeared and the cells entered a second cycle of cell division. The ability of cells to complete a second division was examined by shifting the cells from 39 C to 35 C during different phases of the first mitotic cycle after the enzyme treatment. Incubation of S phase cells at 35 C for 6 hr did not induce a second round of division. These results suggest that expression of the transformed phenotype in 121-6-5 cells is dependent upon both temperature and stage of mitosis. (26 refs)

79-6436 Kinetics of Reentry of Polyoma Progeny Form I DNA into Replication as a Function of Time Postinfection. (Eng) Roman, A. (Dept. Microbiology and Immunology, Indiana Univ. Sch. Medicine, Indianapolis, IN 46223). *Virology* 96(2): 660-663; 1979.

The fate of polyoma progeny Form I molecules was monitored at different times in the replication cycle. Molecules labeled by a 20-min pulse of [^3H]thymidine at 20 hr postinfection (PI) reentered replication at a greater rate than molecules labeled at 28 hr PI. In addition, a greater proportion of molecules labeled at 20 hr PI reentered replication than molecules labeled at 28 hr PI. However, regardless of the time postinfection examined, progeny molecules appeared to be removed from the replicating pool approx 3 hr following their initial synthesis. When replication was monitored by a continuous label of [^{14}C]BUDR, labeled molecules substituted with BUDR in both strands accumulated continuously for at least 6 hr. (5 refs)

79-6437 Cell-Free Assembly of a Polyoma-like Particle from Empty Capsids and DNA. (Eng) Barr, S. M. (Dept. Cellular and Developmental Biology, Univ. Arizona, Tucson, AZ 85721); Keck, K.; Aposhian, H. V. *Virology* 96(2): 656-659; 1979.

Conditions for the cell-free formation of a stable polyomalike particle (PLP) whose DNA is resistant to the action of pancreatic DNase are reported. A PLP is formed when polyoma DNA and purified empty capsids are incubated in a cell-free system. The DNA of this new particle is protected against the action of pancreatic DNase. The density of the purified PLP in CsCl is 1.32 g/cm^3 , which is intermediate between that of polyoma virions

(1.34 g/cm³) and empty capsids (1.29 g/cm³). Purified PLP sediments at 190S in sucrose and is stable in solns of high ionic strength. The DNA extracted from PLP with the use of a detergent and phenol is double-stranded with a mol wt of approx 1.1×10^6 . The particles are stable in CsCl at 4 C for at least 5 mo. Electron micrographs indicate that highly purified PLP's stained with 2% phosphotungstic acid have the same appearance as polyoma capsids. Neither aggregates nor complexes bound by loose ionic bonds appear reasonable to explain these results. The evidence indicates that the DNA of this new PLP is protected by the capsid. (8 refs)

- 79-6438 Comparisons of Two Early Gene Functions Essential for Transformation in Polyoma Virus and SV-40. (Eng) Fluck, M. M. (Dept. Microbiology and Public Health, Michigan State Univ., E. Lansing, MI 48824); Benjamin, T. L. *Virology* 96(1): 205-228; 1979.

Temperature-sensitive (ts-a) mutants of polyoma virus (PV) were compared with ts-A mutants of simian virus 40 (SV40), and host range transformation defective (hr-t) mutants of PV were compared with the viable deletion mutants of SV40 mapping between 0.54 and 0.59 map units (dl mutants). All four groups of mutants were either totally or partially defective in inducing stable transformation, as assayed by anchorage-independent growth. Two distinct functions essential for transformation were encoded within the early regions of these papovaviruses, and two approaches were taken to define the roles of these early viral genes in cell transformation. In the first approach, a clonal analysis was made of cells transformed at the permissive temperature by ts-a/A mutants. The majority of clones showed no temperature dependence of either selected or unselected properties when compared with wild-type virus-transformed clones. No correlation was seen between the appearance of a temperature-sensitive phenotype in individual clones and the expression of tumor-antigen species at permissive and nonpermissive temperatures. In the second approach, mutants of all four groups were tested for their ability to induce abortive transformation, as measured by the transient loss of anchorage-dependent growth. The ts-a/A mutagens retained their ability to induce abortive transformation, behaving like wild-type virus at the nonpermissive temperature. The hr-t mutants were negative, whereas the dl mutants showed a reduced ability to induce abortive transformation. (115 refs)

- 79-6439 Interrupting the Early Region of Polyoma Virus DNA Enhances Tumorigenicity. (Eng) Israel, M. A. (DNA Recombinant Unit, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD 20205); Simmons, D. T.; Hourihan, S. L.; Rowe, W. P.; Martin, M. A. *Proc Natl Acad Sci USA* 76(8): 3713-3716; 1979.

The tumorigenicity of DNA from polyoma virus after cleavage with a variety of restriction enzymes was evaluated in suckling Syrian hamsters. Cleavage with enzymes that interrupt the region of the genome coding for the large tumor (T) antigen of polyoma virus markedly enhanced the tumorigenicity above that observed with DNA I of the virus. Cell lines established in vitro from tumors induced by polyoma virions, polyoma virus DNA I, or polyoma virus DNA that had been cleaved with restriction endonucleases in the early region all contained the polyoma virus middle and small T antigens but not the large T antigen. These findings indicate that the large T antigen of polyoma virus is not required for the maintenance of the transformed state and probably not for the initiation of tumorigenesis by viral DNA. (32 refs)

- 79-6440 Structural Changes in Simian Virus 40 Chromatin as Probed by Restriction Endonucleases. (Eng) Liggins, G. L. (Hyland Div., Travenol Lab., Inc., Round Lake, IL 60073); English, M.; Goldstein, D. A. *J Virol* 31(3): 718-732; 1979.

The structure of simian virus 40 (SV40) chromatin was studied through its use as a substrate for single- and multiple-site bacterial restriction endonucleases. Approximately the same fraction of the chromatin DNA was cleaved by each of three different single-site endonucleases, indicating that the nucleosomes do not have unique positions with regard to specific nucleotide sequences within the population of chromatin molecules. However, the extent of digestion was strongly influenced by salt concentration. At 100 millimolar (mM) NaCl-5mM MgCl₂, only about 20% of the SV40 DNA I in chromatin was converted to linear SV40 DNA II. In contrast, at lower concentrations of NaCl (0.05 or 0.01 M), an additional 20 to 30% of the DNA was cleaved. These results suggest that at 100 mM NaCl only the DNA between nucleosomes was accessible to the restriction enzymes, whereas at the lower salt concentrations, DNA within the nucleosome regions became available for cleavage. When SV40 chromatin was digested with multiple-site restriction enzymes, less than 2% of the DNA was digested to limit digest fragments, whereas only a small fraction (9% to 15%) received two or more cuts. Instead, the principal digest fragment was full-length linear SV40 DNA II. The failure to generate limit digest fragments was not a consequence of reduced enzyme activity in the reaction mixtures or of histone exchange. When the position of the principal cleavage site was mapped after *HpaI* digestion, it was found that this site was not unique. Nevertheless, all sites were not cleaved with equal probability. An additional finding was that SV40 chromatin containing nicked-circular DNA II produced by random nicking of DNA I was also resistant to digestion by restriction enzymes. These results suggest that the initial cut which causes relaxation of topological constraint in SV40 chromatin DNA imparts resistance to further digestion by restriction enzymes. This effect may be accomplished by either "winding" of the internucleosomal DNA into the body of the nucleosome or by successive right-hand rotation of nucleosomes. (66 refs)

- 79-6441 A Poly(dT)-stimulated ATPase Activity Associated with Simian Virus 40 Large T Antigen. (Eng) Giachero, D. (Dept. Biochemistry, Univ. Illinois, Urbana, IL 61801); Hager, L. P. *J Biol Chem* 254(17): 8113-8116; 1979.

Highly purified SV40 large T antigen ATPase activity was stimulated approx 7-fold by the DNA homopolymer poly(dT). The poly(dT)-stimulated enzyme hydrolyzed various ribonucleotide and deoxyribonucleotide triphosphates, with ATP and deoxyATP serving as the best substrates. Purified large T antigen hydrolyzed ATP to adenosine diphosphate and inorganic phosphate (P_i), with a max specific activity of 13.5 μ moles of P_i released per hr per mg of protein. Of the various natural and synthetic polynucleotides tested, poly(dT) was by far the best activator. Long chain poly(dT) molecules proved to be much more effective activators than short chain length oligo(dT) molecules. The highly purified large T antigen contained no detectable protein kinase activity. (30 refs)

- 79-6442 Papovaviruses as Vehicles for the Transduction of Foreign Genes into Mammalian Cells. (Eng) Upcroft, P. (Dept. Microbiology and Immunology, Univ. California, Los Angeles, CA 90024); Ziemer, F.; Skolnik, H.; Fareed, G. C. *Brookhaven Symp Biol* (29): 207-217; 1978.

The hybrid simian virus 40 (SV40)-*Escherichia coli* DNA (SV40-*su*+III), which conserves the origin of replication and the A gene function of SV40, was found to transform secondary rat embryo cells, using the calcium transfection technique. Reassociation kinetics confirmed that the rat cells were transformed by DNA that had the structure of the hybrid SV40-*su*+III. Both SV40 and *E. coli su*+III DNA sequences were localized by hybridization on specific DNA fragments. An unexpected observation was the presence of free (unintegrated) as well as integrated hybrid viral DNA sequences. In another experiment, the TC7 subline of CV-1 African green monkey kidney cells was infected with the SV40-*su*+III DNA by the DEAE-dextran procedure and 48 hr later the cells were subcultured and serially diluted for cell cloning. Of a large number of cloned lines from the original DNA-infected cell culture, two cell populations that carried substantial amounts of free DNA were identified. Subcloning of cells from these persistently infected cell cultures revealed the persistence of free viral DNA in most subclones and expression of SV40 intranuclear T antigen. These studies show that both the SV40 vector and bacterial DNA sequences remain associated with transformed rat embryo cells and persistently infected monkey kidney cells. (19 refs)

- 79-6443 Simian Virus 40 Gene Expression in Permissive, Nonpermissive, and Virus-resistant Cells. (Eng) Graessmann, A. (Inst. Molecular Biology and Biochemistry, Free Univ. Berlin, West Berlin 33, W. Germany); Graessmann, M.; Mueller, C. *Brookhaven Symp Biol* (29): 197-206; 1978.

Simian virus 40 (SV40) gene expression was compared in infected nonpermissive 3T3 mouse cells and in 3T3 cells microinjected with viral DNA. In virus-infected cells, both the onset of accumulation of intranuclear T-antigen and the proportion of T-antigen-positive cells correlated with the multiplicity of infection (MOI). When confluent infected mouse cells were stimulated for DNA synthesis, there was neither demonstrable viral DNA replication nor viral capsid antigen (V-antigen) synthesis, even at a MOI of 1,000 plaque-forming units. However, T-antigen synthesis was demonstrable in 3T3 cells at 12 hr and V-antigen synthesis at 24 hr after microinjection of 1 mg DNA I/ml injection buffer. SV40 V-antigen synthesis was directly correlated with the number of injected DNA I molecules. Late SV40 gene expression appears to require the efficient synthesis of the virus-coded T-antigen. In both nonpermissive mouse cells and permissive monkey cells, V-antigen synthesis was demonstrable only if a threshold amount of intranuclear T-antigen was obtained. When isolated SV40 replicative intermediate DNA (RI-DNA) was microinjected into monkey kidney cells preincubated with an inhibitor of DNA synthesis, 30% of the recipient cells synthesized SV40 V-antigen within 24 hr. Following a 10-fold higher amount of DNA I, only T-antigen was detectable. These results indicate that late viral gene transcription depends on the availability of a template structure generated during the process of viral DNA replication. (23 refs)

- 79-6444 Sites Including Those of Origin and Termination of Replication Are Not Freely Available to Single-Cut Restriction Endonucleases in the Supercompact Form of Simian Virus 40 Minichromosome. (Eng) Das, G. C. (Univ. Tennessee-Oak Ridge Graduate Sch. Biomedical Sciences, Oak Ridge, TN 37830); Allison, D. P.; Niyogi, S. K. *Biochem Biophys Res Commun* 89(1): 17-25; 1979.

Conditions for the isolation of compact forms of the simian virus 40 (SV40) minichromosome from both virions and infected African green monkey kidney cells (BSC-1) were studied.

Minichromosomes isolated from both virions (MV) and infected cells (MI) had highly compact structures in buffer containing 0.15 M NaCl, and they sedimented with S values of about 90-100 and 115-130, respectively. MI also appeared to be the more compact of these structures under the electron microscope. Only 30%-35% of the sites of origin and termination of replication in MV were freely available to the restriction endonucleases *Bgl*I and *Bam*HI. MV were similarly resistant to *Eco*RI and *Hpa*II. In contrast, almost no sites in MI were available to any of these single-cut endonucleases. In 0.6 M NaCl, MV and MI changed to relaxed structures of 45S-55S and 50S-60S, respectively, containing 20-24 nucleosomes per genome. They also became more sensitive to *Bgl*I, *Bam*HI, *Eco*RI, and *Hpa*II. (28 refs)

- 79-6445 Antigenic Relationship of SV40 Early Proteins to Purified Large T Polypeptide. (Eng) Lanford, R. E. (Dept. Virology, Baylor Coll. Medicine, Houston, TX 77030); Butel, J. S. *Virology* 97(2): 295-306; 1979.

Rabbit antiserum was produced against SV40 large T antigen purified by immunoprecipitation and sodium dodecyl sulfate (SDS)-polyacrylamide gel electrophoresis. This antiserum immunoprecipitated both large T and small t antigens and reacted with SV40, T, U, and S antigens by immunofluorescence. These data establish the antigenic relatedness of all the known SV40 early gene products, with the exception of transplacental antigen activity, and confirm the virus-specific nature of each. The reactivity of the anti-T polypeptide serum was compared with the specificities of T-reactive antisera produced by different methods, including conventional tumor-bearing hamster sera, rabbit antiserum directed against whole-cell SDS-lysates of SV40-transformed rabbit kidney cells, and high-liter ascites fluid from hamsters (ascites induced by injection of SV40-transformed hamster ascites cells). Each of the antisera was reactive in all of the tests for SV40-induced early antigens, but the relative reactivity toward each protein varied considerably. It is postulated that the differences in reactivity to small t antigen and U antigen represent differences in the immune response of individual animals to the amino and carboxyl termini of the large T antigen polypeptide, respectively. Antiserum produced against the SDS-denatured large T polypeptide exhibited the highest reactivity to both small t and U antigenic sites relative to its reactivity against intranuclear large T antigen. (50 refs)

- 79-6446 The Influence of Fluorophenylalanine on the Synthesis of Simian Virus 40 DNA and T Antigens. (Eng) Kress, M. (Unites d'Immunologie et de Physiologie des Virus, Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, 94800 Villejuif, France); Girard, M. *Biochimie* 61(3): 419-423; 1979.

The influence of fluorophenylalanine (FPA) on the synthesis of simian virus 40 (SV40) DNA and tumor (T) antigens was investigated in CV1 monkey cells infected with the VA 4554 strain of SV40. Treatment of these cells with FPA resulted in an increased uptake of thymidine by the cells and progressive inhibition of both viral and cellular DNA synthesis. Viral DNA synthesis was more sensitive to the inhibition than cellular DNA synthesis. SV40 T-antigen synthesis was unaffected by FPA, as judged from the results of immunofluorescence assays. The mol wt of the major polypeptides immunoprecipitated from cell extracts by antibodies from tumor-bearing hamster sera was also unaffected. It is suggested that T antigen synthesized in the presence of FPA is non-functional. (22 refs)

- 79-6447 Roles of the Simian Virus 40 Tumor Antigens in Transformation of Chinese Hamster Lung Cells: Studies with Simian Virus 40 Double Mutants. (Eng) Martin, R. G. (Lab. Molecular Biology, Natl. Inst. Arthritis, Metabolism and Digestive Diseases, NIH, Bethesda, MD 20205); Setlow, V. P.; Edwards, C. A. *J Virol* 31(3): 596-607; 1979.

Simian virus 40 (SV40) mutants containing both a *tsA* mutation [rendering the 90,000 mol wt (90K) T-antigen thermolabile] and a deletion between 0.54 and 0.59 map units (reducing the size and amount of the 20K t-antigen) were used to study the roles of SV40 tumor antigens in the transformation of Chinese hamster lung (CHL) cells. SV40 mutants with deletions between 0.54 and 0.59 map units failed to transform resting cells; but actively growing CHL cells were transformed at comparable rates by wild-type, *tsA*, and *tsA*-deletion mutant virus. The frequency of transformation by the double mutants was markedly reduced relative to the *tsA* mutants when resting rather than growing cells were used in the transformation assays. The double mutants, like the *tsA* mutants, were unable to transform growing or resting CHL cells at the nonpermissive temperature. Growth-arrested cells were transformed by the deletion mutants at less than 2% the frequency found when the 20K t-antigen was normal. Growth arrest had very little effect on the temperature sensitivity of the resulting transformed cell line whether or not the deletion was present. (24 refs)

- 79-6448 Assessment of Host Immune Status During Progressive Growth and After Excision of DNA Virus (Simian Virus 40) Tumors in Hamsters: Comparison of Tumor-specific and Tumor-unrelated Parameters of Immune Responsiveness. (Eng) Houston, K. J. (Dept. Medicine, Univ. Medical Center, Jackson, MS 39216); Blasecki, J. W. *J Natl Cancer Inst* 63(3): 665-673; 1979.

The kinetics of cellular immune responses to simian virus 40 (SV40) tumor-specific transplantation antigen (TSTA) were compared with the kinetics of responses to T- and B-cell mitogens and tumor-unrelated antigens in inbred MHA/SsLAK hamsters during the course of progressive syngeneic SV40 tumor growth and following tumor excision. Using the tumor cell neutralization test in vivo and the macrophage migration inhibition assay in vitro, specific cellular immunity to TSTA was detected within 4 days after tumor cell inoculation, when the tumor was small; this response was no longer detected after 7 days, when the tumor had reached a diameter of 12.5 mm, but it returned 14 days after tumor excision. The kinetics of the mitogen responses of spleen cells from tumor bearing hamsters generally showed a lack of correlation with the kinetics of tumor-specific cellular immunity. Suppression of the response to pokeweed mitogen was observed 14 days after tumor inoculation, and suppression of phytohemagglutinin responsiveness was detected 21 days after inoculation. Concanavalin A responses were either at or above control levels at all times. The kinetics of the humoral immune response to murine RBC correlated much more closely with the kinetics of tumor-specific immunity than did the responses to mitogens. IgG antibody (T-dependent) responses were more affected by progressive tumor growth than were IgM (T-independent) responses. The data suggest that, when tumor-unrelated assay procedures are used to assess the immune status of cancer patients, an accurate picture may not be obtained even with a battery of such tests. (43 refs)

- 79-6449 Reactivation of Silent rRNA Genes by Simian Virus 40 in Human-Mouse Hybrid Cells. (Eng) Soprano, K.

J. (Dept. Pathology and Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA 19140); Dev, V. G.; Croce, C. M.; Baserga, R. *Proc Natl Acad Sci USA* 76(8): 3885-3889; 1979.

Mouse-human hybrid cells were used to study the ability of simian virus 40 to regulate the expression of ribosomal RNA (rRNA) genes in vivo. In these hybrid cells, only the rRNA genes of the dominant species are expressed. The genes for the rRNA of the recessive species are silent. Simian virus 40 infection of the hybrids led to the production of two distinct 28S rRNA species as analyzed by agarose/2.4% polyacrylamide gel electrophoresis. These species were identified as human and mouse rRNAs. This result was confirmed by histochemical studies that indicated that the nucleolus organizer regions of both mouse and human chromosomes were actively synthesizing rRNA in the virus-infected hybrid cells. These results indicate that simian virus 40 infection can induce the expression of otherwise silent rRNA genes. (29 refs)

- 79-6450 Evidence for Non-spliced SV40 RNA in Undifferentiated Murine Teratocarcinoma Stem Cells. (Eng) Segal, S. (Lab. Experimental Pathology, NIAMDD, NIH, Bethesda, MD 20014); Levine, A. J.; Khoury, G. *Nature* 280(5720): 335-338; 1979.

The F-9 line of mouse teratocarcinoma cells infected with simian virus 40 (SV40) was used to study the basis for the absence of expression of SV40 genetic information in such cells. Using polyacrylamide gel electrophoresis, two distinct polypeptides with apparent mol wts of 105,000 and 55,000 were identified after immunoprecipitation with anti-SV40 tumor (T) serum. SV40 T antigens were not detected in the infected F-9 cells. The in vitro sarkosyl method for the detection of viral transcription demonstrated that viral transcription was initiated in SV40-infected F-9 cells, substantial fractions of viral transcription being initiated on both early and late viral DNA strands. Determinations of the proportion of the SV40 genome that is transcribed in vivo demonstrated the presence of two spliced early SV40 messenger RNA's (mRNA's) coding for T and t antigens. Spliced early mRNA was shown to be synthesized during the infection of differentiated mouse embryo cells by SV40, the mature cytoplasmic spliced RNA's being derived from this primary transcript. The data indicate that a major block to SV40 gene expression in F-9 cells is related to their inability to splice the primary transcripts. (27 refs)

- 79-6451 The 55K Protein on the 5' Termini of Adenovirus Type 2 DNA Is Unrelated to Virus-coded Candidate Transformation Proteins (E1-53K, E1-40K-50K) and DNA-Binding Proteins (E2-42K/47K/73K). (Eng) Green, M. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, St. Louis, MO 63110); Wold, W. S.; Brackman, K. H.; Cartas, M. A. *J Virol* 31(3): 836-840; 1979.

Further investigations are reported on a polypeptide of 55,000 daltons (55K) that has been shown to be linked, probably covalently, to the 5'-termini of adenovirus type 2 DNA, is synthesized during early stages of infection, and thus may function in viral DNA replication, gene regulation, or cell transformation. Several virus-coded early polypeptides have been identified that could correspond to the terminal 55K, including the E1-40K-50K and E1-53K candidate transformation polypeptides and the E2-42K/47K/73K single-stranded DNA-binding polypeptide. Two-dimensional trypt-

tic [35 S]methionine-peptide maps of the terminal 55K, however, differed completely from [35 S]methionine-peptide maps of four related E1-40K-50K polypeptides, the E1-53K, and the related E2-42K, E2-47K, and E2-73K polypeptides. It was concluded that the terminal 55K polypeptide does not correspond to any of the known virus-coded early polypeptides. (18 refs)

- 79-6452 Adenovirus Type 2 Terminal Protein: Purification and Comparison of Tryptic Peptides with Known Adenovirus-coded Proteins. (Eng) Harter, M. L. (Cold Spring Harbor Lab., Cold Spring Harbor, New York, NY 11724); Lewis, J. B.; Anderson, C. W. *J Virol* 31(3): 823-835; 1979.

The protein covalently bound to the 5' termini of adenovirus type 2 DNA was purified from virus labeled with [35 S]methionine. Using exclusion chromatography of disrupted virions, the DNA-protein complex was isolated and was then digested with DNase. The terminal protein isolated from mature virus was most effectively labeled if the cells were exposed to [35 S]methionine during the "intermediate" period of 13 to 21 hr postinfection, suggesting that the protein is synthesized during this interval. The tryptic peptides of the terminal protein were compared with those of several known adenovirus-coded proteins and found to be unrelated. In particular, the terminal protein was not related to the 38-50K early proteins encoded by the leftmost 4.4% of the adenovirus genome, one region essential for the transforming activity of the virus; nor was it related to the 72K single-strand-specific DNA binding protein, the minor virion component IVa₂, or the major capsid component hexon. (45 refs)

- 79-6453 A Spliced Sequence at the 5'-Terminus of Adenovirus Late mRNA. (Eng) Berget, S. M. (Center Cancer Res., Massachusetts Inst. Technology, Cambridge, MA 02139); Sharp, P. A. *Brookhaven Symp Biol* (29): 332-344; 1978.

Poly(A)-containing RNA was isolated from polyribosomes prepared 32 hr after infection with adenovirus type 2 (Ad2) and fractionated on polyacrylamide gels. The predominant viral messenger RNA (mRNA) isolated by this procedure was that coding for the major virion capsid polypeptide, hexon (II). This RNA was mapped by hybridizing the purified hexon (II) mRNA to restriction endonuclease fragments of Ad2 DNA under R-loop conditions and ultrastructural study of the hybrids. The hexon (II) mRNA mapped within 51.7 and 61.3 units on the viral genome. Electron microscopy of hybrids formed between purified hexon (II) mRNA and single-stranded *Hind*III A DNA showed that the 5'-end of hexon (II) mRNA consists of 160 bases of RNA covalently attached to the main body of the RNA and not coded for by DNA sequences adjacent to those coding for the rest of the mRNA. Experiments involving hybridization of purified hexon (II) mRNA to single-stranded Ad2 *Eco*RI A DNA indicated that these spliced sequences are complementary to three regions of the viral genome located at 17, 20, and 27 units. These three sequences are arranged tandemly in the tail sequences in the order in which they are found on the genome, which suggests that the leader sequences might have become attached to the remainder of the mRNA following looping back, excision, and ligation of an initial large nuclear transcript. This model requires the existence of an RNA ligase in mammalian cells and some control element, either a protein or a small RNA. (29 refs)

of Human Adenovirus Type 2. (Eng) Green, M. (Inst. Molecular Virology, St. Louis Univ. Sch. Medicine, 3681 Park Ave., St. Louis, MO 63110); Wold, W. S.; Brackmann, K. H.; Cartas, M. A. *Virology* 97(2): 275-286; 1979.

Antisera against four lines of adenovirus (Ad) 2-transformed rat cells, including F17 cells which contain only early gene region 1 (map position 1.5-11, the transforming region), can immunoprecipitate major polypeptides of 53,000 (53K) and 15,000 (15K) daltons. The 53Ks precipitated by three of these antisera as well as Ad1-SV40 induced hamster tumor sera were all shown to possess identical two-dimensional tryptic [35 S]Met-peptide maps. Similarly, all 15Ks precipitated by these antisera had identical maps. Tryptic and chymotryptic maps demonstrated that most if not all of the [35 S]Met-peptides of 15K are shared by 53K. Four [35 S]Met-labeled polypeptides of 40K-50K, specific to Ad2 early infected human cells, were isolated in O'Farrell-type 2D gels. These polypeptides are coded within map position 1.5-4.5, whereas the 53K and 15K are coded within map position 4.5-11. As expected, tryptic and chymotryptic peptide maps of these four polypeptides indicated no relationship to 53K or 15K. Two of the 40K-50K polypeptides were highly related, the other two were highly related, and all four were partially related. In addition to 53K and 15K, the F17 antiserum precipitated a 28K polypeptide and minor bands of 14K-16K, 18K-20K, and 11K-12K. Tryptic and chymotryptic maps of these polypeptides showed that 14K-16K and 18K-20K polypeptides are members of the 53K/15K family, 11K-12K polypeptides are related to each other but are unrelated to any other polypeptides, and 28K is unrelated to any other polypeptides. It was concluded that early region 1 codes for two (53K/15K family, 40K-50K family) or possibly more (eg, 11K-12K family) families of polypeptides; the polypeptides included in each family overlap in amino acid sequence and therefore may be translated from overlapping spliced messenger RNAs. The possible contribution of these polypeptides to the phenotype of Ad2-transformed cells is discussed. (48 refs)

- 79-6455 Protease of Adenovirus Type 2: Partial Characterization. (Eng) Bhatti, A. R. (Departement de Microbiologie, Centre Hospitalier Universitaire, Université de Sherbrooke, Sherbrooke, Quebec J1H 5N4, Canada); Weber, J. *Virology* 96(2): 478-485; 1979.

An adenovirus type 2 (Ad2)-associated protease activity specific for the cleavage of core polypeptide PVII to polypeptide VII was identified, and its properties were studied in an in vitro assay system. All temperature-sensitive (ts) mutants examined failed to induce protease activity at 39 C. Activity was restored in the revertants. The protease activity was inhibited completely by 1 mM tosylamide phenylethylchloromethyl ketone, but phenylmethylsulfonylfluoride and tosyllysinechloromethyl ketone at 1 mM reduced enzyme activity to 36% and 10% of control values, respectively. In contrast, EDTA had no effect. Optimum enzyme activity was observed at neutral pH. Enzyme activity was stable up to, but not beyond, 45 C. Polypeptide PVII was cleaved whether it was in the soluble, bound, or heat- or acid-precipitated form. Wild-type young virions contained endogenous protease activity, but the virions produced at 39 C by ts1-infected cells did not. The PVII contained in these ts1-39 virions, however, may be processed by exogenous wild type enzyme after the particles have been frozen-thawed several times. These results suggest that Ad2-associated protease is a chymotrypsinlike, nonmetallo-, neutral protease. (26 refs)

- 79-6454 Identification of Families of Overlapping Polypeptides Coded by Early "Transforming" Gene Region I

- 79-6456 In Vitro Translation Products Specified by the Transforming Region of Adenovirus Type 2. (Eng)

Halbert, D. N. (Dept. Pathology, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO 63110); Spector, D. J.; Raskas, H. J. *J Virol* 31(3): 621-629; 1979.

Proteins specified by purified region 1 RNAs of adenovirus type 2 were characterized. Region 1 RNAs were purified by hybridization selection, using restriction fragments bound to nitrocellulose membranes, and by size fractionation. The isolated RNAs were then translated in cell-free systems derived from wheat germ and rabbit reticulocytes. The family of RNAs specified by 0 to 4.4 sequences includes two RNAs, which are 12S and 13S in size; these were partially separated by mol wt and translated. The 13S RNA produced 53,000-dalton (53K) and 41K peptides, and the 12S RNA synthesized 47K and 35K products. The family of RNAs mapping from 4.4 to 11.0 encoded three separate polypeptides, each of which could be assigned to a specific RNA. A 12K product that comigrated with structural polypeptide IX was synthesized from the 9S RNA, as previously reported. The 13S RNA encoded a 15K polypeptide that corresponded to a 15K polypeptide in infected cell extracts. The 22S RNA encoded a 52K protein distinct from the 0 to 4.4 polypeptides. (46 refs)

79-6457 On the Mechanism of Arginine Requirement for Adenovirus Synthesis. (Eng) Plaat, D. (Departement de Microbiologie, Centre Hospitalier Universitaire de l'Université de Sherbrooke, P.Q., J1H 5N4, Canada); Weber, J. *Arch Virol* 60(3/4): 187-196; 1979.

The effects of arginine (AG) deprivation at different times during infection with human adenovirus type 2 on the synthesis and processing of viral proteins, on the assembly of incomplete and complete virions, and on the activity of polypeptide PVII-specific endoprotease were studied. AG deprivation greatly reduced the synthesis of all viral proteins, particularly the precursor to core protein VII. The inhibition was completely reversible by the addition of AG to the medium. AG deprivation between 7 and 20 hr postinfection inhibited the processing of PVII to VII, suggesting that PVII is not cleaved autocatalytically. The assembly of incomplete virions was sensitive to AG deprivation between 0 and 20 hr postinfection, but the assembly of complete virions was dependent on the continuous presence of AG. This observation supports the hypothesis that incomplete virions are precursors of complete virions. Experiments on PVII-specific endoprotease activity showed that AG deprivation caused only a slight reduction in *in vitro* activity, although no activity was observed *in vivo*. The results lead to the hypothesis that AG deficiency inhibits the synthesis of a functional protein essential for virion maturation, other than the synthesis or processing of PVII. (18 refs)

79-6458 Association of Tumor Induction by Ultraviolet Light-inactivated Adenovirus 2-Simian Virus 40 Recombinants with a Specific Segment of Simian Virus 40 DNA. (Eng) Lewis, A. M. (Office Scientific Director, Natl. Inst. Allergy and Infectious Diseases, NIH, Public Health Service, Dept. Health, Education and Welfare, Bethesda, MD 20205); Cook, J. L. *J Natl Cancer Inst* 63(3): 695-705; 1979.

The development of virus-induced tumors was studied in Syrian golden hamsters neonatally inoculated sc with 0.1 ml of adenovirus type 2 (Ad2), nondefective (ND) Ad2-Simian virus 40 (SV40) hybrids (Ad2*ND₂ and Ad2*ND₄), or B55 virus that had been inactivated by UV. Four of 27 and 3/34 hamsters inoculated with UV-inactivated Ad2*ND₄ virus, which contains the segment of the SV40 genome between map positions 0.11 and 0.59,

developed tumors; 1/33 hamsters inoculated with the inactivated B55 hybrid developed tumors. One of 31 animals inoculated with 8-16 U of Ad2-neutralizing antibody also developed a tumor. The tumors were either SV40-type fibrosarcomas (4/9), Ad2-type small cell sarcomas (2/9), or a mixture of these types (3/9). Ad2 and the Ad2*ND₂ hybrid, which contains the segment of the SV40 genome between map positions 0.11 and 0.43, were not oncogenic after inactivation by UV. Tumors removed from hamsters inoculated with the inactivated Ad2*ND₄ and B55 viruses contained serologically detectable virus-specific Ad2 T- and SV40 T-antigens. Ad2- and SV40-specific antibodies were detected in sera from hamsters carrying primary and transplanted neoplasms by complement fixation and fluorescent antibody assays. These results indicate that the incorporation of a specific segment of SV40 DNA into the Ad2 genome can alter the pathogenesis of the Ad2*ND₄ virus by rendering it oncogenic for hamsters. (58 refs)

79-6459 Type C Particles in Culture of Human Glioblastoma Cells. (Eng) Yutani, C. (Dept. Pathology, Natl. Cardiovascular Center, 125 Fujishirodai Suita, Osaka 565, Japan); Satoh, M.; Kanai, N.; Kitamura, H.; Hori, M.; Hayakawa, T.; Nakagawa, H.; Sakamoto, Y.; Nakata, Y. *Acta Pathol Jpn* 29(4): 643-652; 1979.

Biochemical, virological, and electron microscope studies were made of a human glioblastoma cell culture after 10-15 passages. The cultures produced reverse transcriptase activity. ³H-uridine was incorporated into particles with a buoyant density of 1.07 g/ml, equal to that of oncornavirus (OV) particles. ³H-thymidine was not incorporated, which suggests that the virus particles contain only RNA as their nucleic acid. Reverse transcriptase activity was also demonstrated in the particles, suggesting that the cultured human glioblastoma cells were producing C-type OV. Ultrastructural observations of the cell culture showed many viruslike particles whose morphological features were characterized by three electron-dense, ring-shaped, membranelike shells (envelope) surrounding a relatively electron-lucent core, consistent with mature OV. The mean diameter of the particles was approx 100 nanometers (nm). Spikes measuring 1.1 nm protruded from the outer layer. Budding of the virus was seen on the surface of the tumor cells. (18 refs)

79-6460 Assay of Mouse-Cell Clones for Retrovirus p30 Protein by Use of an Automated Solid-State Radioimmunoassay. (Eng) Kennel, S. J. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Tennant, R. W. *Virology* 97(2): 464-467; 1979.

A solid-state radioimmunoassay (SS-RIA) was developed for retrovirus protein p30 that is suitable for large-scale application. Secondary antibody bound to Sepharose beads is used to bind antigen-antibody complexes, which can subsequently be separated from free antigen by an automated cell harvester in a microtiter plate system. Using this assay, 50% competition was achieved with 1 nanog of unlabeled p30 showing its usefulness for quantitation in the 0.5-5.0 nanog range. Assays for interspecies and type-specific antigenic determinants of p30 were used to identify clones of cells producing this protein. Cell clones identified in the interspecies SS-RIA were assayed for virus production by fluorescent antibody tests. Of 15 clones tested, 11 were positive in the FA test. Clones positive in the SS-RIA for type-specific p30 determinants were analyzed by quantitative fluid-phase RIA; both assays gave identical results. It is claimed that one investigator can analyze up to

1,000 clones/day for p30 production and that the assays are sensitive and give reproducible results. (9 refs)

- 79-6461 Molecular Evidence for a Type C Retrovirus Etiology of the Lymphoproliferative Disease of Turkeys. (Eng) Gazit, A. (Dept. Human Microbiology, Sackler Sch. Medicine, Tel-Aviv Univ., Tel-Aviv, Israel); Yaniv, A.; Ianconescu, M.; Perk, K.; Aizenberg, B.; Zimber, A. *J Virol* 31(3): 639-644; 1979.

The role of a new type C retrovirus isolated from the blood of turkeys infected with lymphoproliferative disease (LPD) in the etiology of LPD was studied. The virus is distinct from the avian leukosis-sarcoma virus complex and the reticuloendotheliosis virus (REV) group. LPD complementary DNA (cDNA) hybridized readily to cellular RNA from LPD tumors but not to that from REV-induced tumors or normal turkey embryos. Approx 0.16% of LPD tumor RNA appeared to be virus specific. REV cDNA did not hybridize with cellular RNA from LPD virus-induced tumors or with RNA from normal turkey tissues. Melting temperatures for RNA-cDNA hybrids of LPD virus and REV were 88 and 85 C, respectively. LPD viral cDNA readily associated with cellular DNA from LPD tumors, the melting point of the hybrids being 82 C. LPD cDNA annealed to a much lower extent with a lower degree of base pair homology (melting point 77 C) with DNA from REV-induced tumors. Normal turkey and chicken DNA and the DNA of other species examined lacked LPD viral sequences, suggesting that LPD virus is not an endogenous virus of turkeys. (32 refs)

- 79-6462 Polypeptide Profile of HBsAg Excreted by a Human Hepatoma Cell Line. (Eng) Monjardino, J. (Div. Cell Studies, Clinical Sciences Building, Royal Free Hosp., Pond St., London NW3 2QG, England); Crawford, E. *Virology* 96(2): 652-655; 1979.

The polypeptide composition of hepatitis B surface antigen (HBsAg) particles secreted by a human hepatoma cell line (Alexander) was analyzed. Five major components with mol wts of 22,000, 28,000, 33,000, 38,000, and 49,000 were identified. The two smaller species (mol wts of 22,000 and 28,000) were found to be the major components. The polypeptide profile was similar to that described for HBsAg derived from the sera of acute hepatitis patients and chronic carriers. Data suggesting that the various HBsAg polypeptide components are aggregates and glycosylated derivatives of the 22,000-dalton polypeptide subunit are presented. (13 refs)

- 79-6463 Possible Role of Viruses or Virus-like Factor(s) in Malignancies of Animal and Microbial Cells. (Eng) Babbar, O. P. (Central Drug Res. Inst., Chattar Manzil Palace, Lucknow-226001, India). *Indian J Med Res* 69: 874-885; 1979.

The possible role of viruses or viruslike factor(s) in animal and microbial cell malignancies was studied. Mortality and lesions or symptoms characteristic of mycoplasma infections were observed in chick embryos and 1-day-old chicks infected with avian mycoplasma strains DPV or F5V but not in those infected with strains F5 or DP. Mortality and disease in plant embryos infected with DPV or F5V were greater than in those infected with DP or F5. Lysates prepared from $2-4 \times 10^7$ DPV cells or $1-6 \times 10^6$ F5V cells caused mortality and typical lesions in chick and plant em-

bryos, whereas 100-fold higher concentrations of lysates from DP or F5 cells were nonlethal in chick embryos and much less harmful in plant embryos. These results suggested that the virulence of DPV and F5V was due to their increased synthesis of toxic factor(s). The biochemical properties of DPV and DP and those of F5V and F5 did not differ, but the duration of exponential phase growth required by DPV and F5V to reach a max concentration of cells was longer than that of DP and F5. DPV and F5V grown in the presence of chick interferon (CIF) lost their virulence for chick embryos and behaved like DP and F5. With increasing CIF concentrations in the growth media, the number of *Salmonella typhimurium* (nonlysogenic) or *Escherichia coli* (lysogenic) required per mouse to cause 50% mortality increased. CIF-induced inhibition of endotoxin production by these organisms led to a corresponding increase in their rate of multiplication. CIF-induced inhibition of the production of exotoxins by *Staphylococcus aureus* and *Clostridium welchii* also led to an increase in their rate of multiplication. CIF appeared to block only those functions of Walker 256 carcinoma cells associated with their malignancy, and it had no direct cytotoxic effect on them. These results indicate that (1) the production of toxins in nonlysogenic pathogenic bacterial cells may be initiated by a cellular gene activated to assume such a function and that (2) malignancy in animal cells may be initiated by genes activated to function as oncogenes. (26 refs)

- 79-6464 Further Characterization of Mengo Subviral Particles: A New Hypothesis for Picornavirus Assembly. (Eng) Lee, P. W. (Dept. Microbiology and Immunology, Duke Univ. Medical Center, Durham, NC 27710); Colter, J. S. *Virology* 97(2): 266-274; 1979.

The "50S particle" found in Mengo virus-infected L cells was further characterized. Centrifugal analysis in sucrose density gradients gave an estimated sedimentation coefficient of 53S. When, during the isolation of 53S particles, the KCl concentration in the suspending buffer was increased to 150 mM or higher, some of the particles were converted to structures having a significantly larger sedimentation coefficient. A similar conversion of 53S to more rapidly sedimenting particles occurred when the former were centrifuged to equilibrium in a CsCl density gradient. The sedimentation coefficient of this new particle was estimated to be 75S. Mol wt determinations of the previously described 14 S particles and of the 53S and 75S particles by means of Sepharose 4B exclusion chromatography suggested that the molecular compositions of these particles are $(\epsilon\alpha\gamma)_3$, $(\epsilon\alpha\gamma)_{25}$, and $(\epsilon\alpha\gamma)_{50}$, respectively. Based on these data and on previously reported evidence suggesting a precursor role for the 53S particles, a new hypothesis for the mechanism of Mengo virus assembly is proposed according to which the viral RNA interacts with either a 75S particle or two 53S particles to form a complex represented by $\text{RNA}[(\epsilon\alpha\gamma)_5]_{10}$ before assembly is completed by the addition of two 14S subunits. - 79-6465 Interaction Between Mitogenic Lectins and Lymphocyte Plasma Membranes. (Rus) Sitkovskii, M. V. (Lab. Physicochemistry Biological Membranes, M. V. Lomonosov State Univ., Moscow, USSR); Shestakova, S. V.; Kozlov, Iu. P. *Biull Eksp Biol Med* 88(7): 89-91; 1979.

An attempt was made to evaluate the possible molecular mechanism of lymphocyte activation. A purified suspension of mesenteric lymph node cells from Wistar rats was incubated with medium containing concanavalin A (Con A) or phytohemagglutinin (PHA). After 14- or 20-hr of incubation, the cells were washed, and Con A or PHA was added again. Replacement of Con A by PHA induced DNA synthesis, but each mitogen alone did not induce DNA synthesis. - 79-6466 Mutagen-induced Disturbances in the DNA of Human Lymphocytes Detected by Antinucleoside Antibodies. (Eng) Bases, R. (Dept. Radiology, Albert Einstein Coll. Medicine, 1300 Morris Park Ave., Bronx, NY 10461); Rubinstein, A.; Kadish, A.; Mendez, F.; Wittner, D.; Elequin, F.; Liebeskind, D. *Cancer Res* 39(9): 3524-3530; 1979.

The antinucleoside antibody (ANA) method for studying the action of alkylating mutagens on the DNA of human cells was applied to human peripheral blood lymphocytes (PBL). N-Methyl-N'-nitro-N-nitrosoguanidine, methyl methanesulfonate, and N-nitrosomethylurea induced immunoreactivity to ANA's in human PBL in vitro. This could also be detected in lymphocytes taken from a patient soon after iv administration of cyclophosphamide. The immunoreactivity response, which indicates denatured DNA or DNA single-strand breaks, was scored by immunofluorescent or immunoperoxidase techniques. Examination of blood from 10 normal subjects showed that $32 \pm 4\%$ (SE) of resting PBL were immunoreactive to ANA's. These naturally occurring immunoreactive lymphocytes were largely accounted for by a subpopulation of thymus-derived lymphocytes bearing the Fc receptor for IgM. The presence of these cells did not interfere with the use of PBL for in vitro measurement of additional immunoreactivity caused by alkylating mutagens. The response proved to be dose dependent; up to 90% of lymphocytes could be rendered immunoreactive. Parallel studies with HeLa cells showed a similar dose-response relationship between mutagen action and immunoreactivity. With some agents, the immunoreactivity technique detected effects at lower concentrations than those at which effects could be detected by HeLa cell survival studies. With N-nitrosomethylurea, measurement of DNA repair synthesis by [³H]thymidine autoradiography showed that in HeLa cells, these two parameters of response to DNA damage increased in parallel. The results provide a new basis for detecting the action of alkylating mutagens on human lymphocytes in vitro or in vivo. (26 refs)

- 79-6467 Idiopathic Paraproteinemia--A Consequence of an Age-related Deficiency in the T Immune System.

Three-Stage Development--A Hypothesis. (Eng) Radl, J. (Inst. Experimental Gerontology TNO, Rijswijk, Netherlands). *Clin Immunol Immunopathol* 14(2): 251-255; 1979.

On the basis of information gained from recent experiments with an animal model of idiopathic paraproteinemia (the aging C57BL mouse), the following stages were hypothesized to occur in the development of this disease. (1) During aging, involution of the thymus and a genetically determined selective decline in certain T-cell populations lead to an impairment of the T-cell functions. The extent and the progression of these changes may be influenced by some extrinsic factors, such as environment, chronic antigenic stimulation, and virus infection. (2) Consequently, cooperation with and control of B cells by the T cells becomes impaired. Restriction of heterogeneity of the immune response and excessive clonal expansions with an overshoot production of homogeneous immunoglobulins-antibodies appear as a result of this imbalance in the immune system network. (3) The repeated mono- or oligoclonal expansions result in a higher probability for either spontaneous or virus-induced mutation of the regulatory genes within a given B-cell clone. In this way, monoclonal proliferation and paraprotein production would continue, even without antigenic stimulation. This intrinsic defect in cell regulation is, however, different from that seen in B-cell malignancies. (28 refs)

- 79-6468 Requirement of Parental T Lymphocytes for the In Vitro Induction of F₁ Hybrid Anti-parent Cytotoxicity. (Eng) Nakamura, I. (Dept. Pathology, State Univ. New York at Buffalo, 232 Farber Hall, Buffalo, NY 14214); Cudkowicz, G. *Eur J Immunol* 9(5): 371-379; 1979.

A model is described in which the induction of primary F₁ anti-parent cell-mediated lympholysis (CML) required the presence of a subpopulation of T lymphocytes, as judged by the lack of induction following T-cell depletion of parental cells by (1) separation on nylon wool columns, (2) treatment with anti-thymocyte-1.2 antiserum and complement, (3) treatment of donor mice with rabbit anti-mouse thymocyte serum, or (4) congenital absence of the thymus in nu/nu donors. The parental T lymphocytes required were relatively mature, as indicated by their resistance to cortisone, persistence after adult thymectomy, and sensitivity to xenogeneic antithymocyte antiserum. T-depleted cell populations retained their ability to induce allogeneic CML. Parental lymphoma cells, spleen cells stimulated by mitogens for T or B lymphocytes, normal cells of central and peripheral lymphoid organs, and peritoneal exudate cells all served to a varying extent as targets for anti-parent cytotoxic effectors (CTL), but there was no close correlation with their ability to serve as stimulators. Spleen or peritoneal exudate cells of athymic mice also served as "antigenic" targets for specific F₁ anti-parent CTL, but they failed to induce the response. Thus, the role of parental T cells in the induction of F₁ anti-parent cytotoxicity was not that of bearing the "antigen." It is concluded that irradiated parental T lymphocytes provide back-stimulation to F₁ hybrid responders, either directly or indirectly via the activation of macrophagelike cells. Under certain circumstances, however, the requirement for parental T cells can be circumvented. (23 refs)

- 79-6469 The Pathology and Homing of a Transplantable Murine B Cell Leukemia (BCL₁). (Eng) Warnke, R. A. (Lab. Experimental Oncology, Dept. Pathology, Stanford Univ., Sch. Medicine, Stanford, CA 94305); Slavin, S.; Coffman, R. L.; Butcher, E. C.; Knapp, M. R.; Strober, S.; Weissman, I. L. *J Immunol* 123(3): 1181-1188; 1979.

The pathology and early and late homing patterns of a spontaneous B cell leukemia (BCL₁) that arose in a BALB/c mouse are described. The most striking gross finding in the original leukemic mouse was massive enlargement of the spleen. Frozen sections stained for κ and λ -light chains showed a homogenous population of λ -bearing B lymphocytes in the white pulp of the spleen including the periarteriolar T cell domains. Five minutes after the iv injection of 5×10^7 or 2.5×10^7 labeled BCL₁ cells, large numbers of labeled cells were present throughout the pulmonary interstitium of BALB/c mice, and small numbers were present in the marginal zones of the spleen. Eighteen hours after injection, a large number of labeled cells were in the spleen, the majority in the marginal zones and in the red pulp; moderate numbers also occurred in the white pulp. Both the number and distribution of cells within the liver were similar at 5 min and 18 hr. The thymus was devoid of labeled cells. In additional mice given 5×10^6 unlabeled BCL₁ cells iv, leukemic infiltrates were not detected until 35 days after injection. Tissues observed grossly, microscopically, and with immunofluorescent staining in the two mice examined at that time were similar to those observed in the original leukemic mouse. It is concluded that this unusual murine B cell neoplasm is a lymphoma with a striking predilection for the spleen and that the other organs, including bone marrow and peripheral blood, are secondarily involved. (24 refs)

- 79-6470 In Vitro Immune Response of Human Peripheral Lymphocytes. IV. Specific Induction of Human Suppressor T Cells by an Antiserum to the T Leukemia Cell Line HSB. (Eng) Hirano, T. (Third Dept. Internal Medicine, Osaka Univ. Medical Sch., Fukushima-ku, Osaka, 553, Japan); Kishimoto, T.; Kuritani, T.; Muraguchi, A.; Yamamura, Y.; Ralph, P.; Good, R. A. *J Immunol* 123(3): 1133-1140; 1979.

An antiserum to the human T leukemic cell line, HSB, absorbed with the autologous B cell line, SB, was tested for complement (C)-mediated cytotoxicity against a variety of human hematopoietic cell lines. T lymphocyte lines HSB and CEM were strongly positive, and line 45 was weakly positive. T lines SKW3 and MOLT-4, five B cell lines (VM, DAUDI, SB, 1788, and BM), and three lines from non-T acute lymphoblastic leukemia (NALL-1), histiocytic lymphoma (U937), and myeloid leukemia (K562) origin were negative. In six normal donors, cytotoxicity of the absorbed antiserum (dHSB) ranged from 23% to 56% of T cells killed at 1:20 dilution. Treatment of purified peripheral blood lymphocyte (PBL) T cells with dHSB and C had no specific effect on their mitogenic responses to phytohemagglutinin (PHA) and concanavalin A (Con A), but partially inhibited mixed lymphocyte culture (MLC) reactions. dHSB and C had no effect on helper T cells or B lymphocytes in pokeweed mitogen (PWM)-induced immunoglobulin production. When dHSB was present during the 7-day culture for PWM-induced immunoglobulin production, there was complete suppression of both IgG and IgM production at a concentration of 1:400. T cells pretreated with dHSB for 3 days and washed were capable of inhibiting immunoglobulin production by normal PBL at ratios <1:100. dHSB-treated B cells had no effect on PWM induction of immunoglobulins. The results show that the dHSB serum does not recognize antigen(s) expressed on the surface on helper T cells and those T cells responding to PHA and Con A, but does recognize T cells responding in MLC and

suppressor T cells in PWM-induced immunoglobulin production. The results further demonstrate that dHSB-treated T cells secrete a soluble factor that suppresses immunoglobulin production by PWM-stimulated PBL. (41 refs)

- 79-6471 Characterization of a Spontaneous Murine B Cell Leukemia (BCL₁). II. Tumor Cell Proliferation and IgM Secretion After Stimulation by LPS. (Eng) Knapp, M. R. (Howard Hughes Medical Inst. Lab., Stanford Univ. Medical Center, Stanford, CA 94305); Severinson-Gronowicz, E.; Schroder, J.; Strober, S. *J Immunol* 123(3): 1000-1006; 1979.

The susceptibility of tumor cells from a spontaneous BALB/c B lymphocyte leukemia (BCL₁) to activation by the polyclonal B cell activator lipopolysaccharide (LPS) was examined. The kinetics of increased [³H]thymidine incorporation by BCL₁ tumor cells after in vitro stimulation with LPS differed from those of normal BALB/c spleen cells. Normal cells showed a peak proliferation on day 3 of culture, while LPS-activated cells showed a peak on day 1. The response to LPS by both cell types showed only a minor dependence on mitogen concentration over a range of 10-500 μ g/ml. The tumor cells responded optimally when cultured at 2.5×10^6 /ml; the response was enhanced in the presence of 5×10^{-5} M 2-mercaptoethanol. Tumor cells from the spleen, but not those from the peripheral blood, could be induced by LPS to secrete IgM. Karyotype analysis of dividing LPS-activated BCL₁ cells showed that the tumor cells themselves proliferated in response to LPS. Immunoprecipitation showed that the light chains on secreted IgM molecules were the λ isotype, which is further evidence that the tumor cells, and not some residual normal B lymphocytes (which secrete IgM bearing both κ and λ light chains), were responding to LPS stimulation. (29 refs)

- 79-6472 Characterization of a Spontaneous Murine B Cell Leukemia (BCL₁). I. Cell Surface Expression of IgM, IgD, Ia, and FcR. (Eng) Knapp, M. R. (Howard Hughes Medical Inst. Lab., Stanford Univ. Medical Center, Stanford, CA 94305); Jones, P. P.; Black, S. J.; Vitetta, E. S.; Slavin, S.; Strober, S. *J Immunol* 123(3): 992-999; 1979.

The surface marker expression of a spontaneous BALB/c B lymphocyte leukemia (BCL₁) was examined. The tumor cells bore surface immunoglobulins that included both μ - and δ -chains associated with the γ light chain. The presence of IgD with BALB/c (Ig^b) allotypic determinants was demonstrated on the surface of tumor cells growing in BAB/14 (Ig^b) animals, demonstrating the endogenous production of IgD by BCL₁ cells. Alloantigens coded for within the murine H-2 complex, including H-2D, H-2K, and I-region products, were identified on the tumor cells. Although normal B lymphocytes are thought to express products coded for within both I-A and I-E subregions, the BCL₁ expressed only normal amounts of I-E subregion products. In addition, H-2 and Ia antigens revealed by 2-dimensional gel electrophoresis exhibited an abnormal pattern of post-translational modifications. The Fc, but not the complement receptor (CR), was present on the surface of tumor cells. The presence of several B cell surface markers suggests that BCL₁ is derived from the B lymphocyte lineage. Since surface IgD and Ia antigens are first seen on mouse cells around the time of birth, after which they are found on most B lymphocytes, the present findings suggest that the BCL₁ tumor represents a later differentiative stage than murine B lymphocyte tumors previously described. The absence of CR may be explained by the immaturity of the BCL₁ cells, the restriction of cells to a CR-negative subpopulation, or to loss of a differentiated function by this cell line. (41 refs)

- 79-6473 Aggressive Biologic Behavior of Basal- and Squamous-Cell Cancers in Patients with Chronic Lymphocytic Leukemia or Chronic Lymphocytic Lymphoma. (Eng) Weimar, V. M. (209 Converse Drive, Jacksonville, NC 28540); Ceilley, R. I.; Goeken, J. A. *J Dermatol Surg Oncol* 5(8): 609-614; 1979.

The aggressive behavior of basal- and squamous-cell carcinomas (BCC and SCC, respectively) in seven patients with chronic lymphocytic leukemia (CLL) or lymphocytic lymphoma (LL) is reported. SCC was first diagnosed 6 yr after the diagnosis of CLL in a 51-yr-old white man, at the same time as CLL in an 80-yr-old man, 2 yr after CLL in a 61-yr-old white man, and 2 yr after LL in a 63-yr-old white man. BCC was first diagnosed 8 yr after diagnosis of CLL in an 88-yr-old white woman, 8 yr after diagnosis of CLL in an 82-yr-old white man, and 6 yr before LL in a 66-yr-old white woman. All patients had normal absolute numbers of T lymphocytes, but the percentage of T cells was decreased in the patients with CLL. The number and percentage of B cells was decreased in two patients with CLL. None of the patients reacted to id tests with common antigens, and they could not be sensitized to dinitrochlorobenzene. The age at onset of the cutaneous cancers was similar to that in the general population, and the cancers were all on sun-exposed skin. However, the incidence of multiple skin cancers was higher (57%) than in the general population (16%), and the incidence of SCC relative to BCC was higher (3:2) than in the general population (1:4). All patients with SCC developed metastases. The data indicate that BCC and SCC may be more aggressive and more resistant to treatment in some patients with CLL or LL. Actinic keratosis in such patients should be treated early and vigorously to prevent transformation into carcinomas, and all BCCs and SCCs larger than 1 cm should be treated by microscopically controlled excision. (25 refs)

- 79-6474 A Chemotactic Inhibitor Produced by Blast Cells and Present in the Serum of a Patient with Acute Lymphoblastic Leukemia. (Eng) Blumenfeld, W. (Dept. Medicine, Univ. California at Los Angeles, Center Health Sciences, Los Angeles, CA 90024); Territo, M. *Blood* 54(2): 412-420; 1979.

A chemotactic factor inhibitor (CFI) found in the serum of a 26-yr-old man with acute lymphoblastic leukemia was characterized. The factor was heat-labile, and it was active against complement-dependent chemotactic factors and against the chemotactic factor produced by *Escherichia coli*. This suggested that the defective chemotaxis in the patient resulted from increased amounts of CFI. Normal sera and sera from seven other patients with acute leukemia also demonstrated heat-labile inhibitory activity against complement-dependent chemotactic factors, but not against the *E. coli*-derived chemotactic factor. Supernatants from cultured lymphoblasts of the patient also possessed CFI activity similar in character to that found in his serum. It is suggested that in vivo, the lymphoblasts were responsible for the chemotactic defect observed in his serum, presumably by manufacturing and releasing a CFI. (12 refs)

- 79-6475 Cultured Human Leukemic Non-T/Non-B Lymphoblasts and Their Stimulating Capacity in "One-Way" Mixed Lymphocyte Reaction. Suggestive Evidence for Early T-Cell or B-Cell Precursors. (Eng) Han, T. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263); Dadey, B.; Minowada, J. *Cancer* 44(1): 136-140; 1979.

The stimulating capacity of cultured leukemia lymphoblasts from five non-T/non-B cell lines in one-way mixed lymphocyte reac-

tions was studied and compared with the stimulating capacities of cultured leukemic T and B lymphoblasts. Lymphoblasts from three non-T/non-B cell lines (NALL-1, NALM-6, and NALM-16) consistently exerted strong stimulation on allogeneic lymphocytes, whereas those from two other non-T/non-B lines (REH and KM-3) consistently failed to stimulate. Leukemic B lymphoid cells from four cell lines consistently excited a strong stimulation, whereas those from four T lymphoid cell lines consistently failed to stimulate allogeneic normal lymphocytes. The data support the hypothesis that leukemic non-T/non-B cells that possess stimulating ability may represent less differentiated leukemic B lymphoid cells (pre-B cells) and that leukemic non-T/non-B cells that possess no stimulating activity may represent pre-T cells. - 79-6476 In Vitro Induction of Cytotoxic Effector Cells Against Human Neoplasms. I. Sensitization Conditions and Effect of Cryopreservation on the Induction and Expression of Cytotoxic Responses to Allogeneic Leukemia Cells. (Eng) Kedar, E. (Lautenberg Center General and Tumor Immunology, Hadassah Medical Sch., Hebrew Univ., Jerusalem, Israel); Raanan, Z.; Kafka, I.; Holland, J. F.; Bekesi, G. J.; Weiss, D. W. *J Immunol Methods* 28(3/4): 303-319; 1979.

The parameters that govern the in vitro sensitization of peripheral blood lymphocytes (PBL) against freshly obtained human leukemia cells were defined using PBL from normal human donors that were sensitized in vitro against allogeneic human acute myelocytic leukemia (AML) cells by a unidirectional mixed lymphocyte-tumor cell culture (MLTC) technique. The cytotoxic responsiveness of the sensitized lymphocytes, determined in vitro by the ^{51}Cr -release assay, varied among individual lymphocyte donors and was generally dependent on the sensitization culture conditions. Induction of cytotoxic effector cells was augmented appreciably by adding minute amounts of the immunopotentiating agent methanol-extracted residue of BCG to the cultures. Responding lymphocytes and stimulating leukemia cells cryopreserved for several weeks in liquid nitrogen were as effective as fresh cells in generating effector lymphocytes; the cytotoxic capacity of previously sensitized lymphocytes was retained by cryopreservation. (42 refs)

- 79-6477 Loss of H-2* Gene Product(s) from an AKR Spontaneous Leukemia. (Eng) Schmidt, W. (Dept. Immunology, London Hosp. Medical Coll., Turner St., London E1 2AD, England); Atfield, G.; Festenstein, H. *Immunogenetics* 8(4): 311-321; 1979.

The H-2 antigenic specificities on the AKR (H-2*) spontaneous leukemia K36 were studied using serological absorption and immunochemical techniques. Of five anti-H-2.23 alloantisera against the private specificity of the H-2* haplotype, two (C23 and WSF7) were cytotoxic for the K36 tumor. Absorption of serum C23 with B10.A cells completely removed activity against B10.A only, whereas absorption with C3H.OH and K36.16 cells removed activity only against C3H.OH and K36.16. Thus, anti-H-2.23 and not anti-H-2.23 activity in the C23 serum appeared to be responsible for the reactions against C3H.OH and tumor. Absorption of serum WSF7 with B10.A removed all reactivity against all test cells, whereas absorption with C3H.OH and K36 removed only reactivity against C3H.OH and K36.16. The concordant reactivity of WSF7 with all three test cells appeared to be directed against an H-2 public specificity common to all and not anti-H-2.23. Cytotoxicity and absorption studies were conducted with sera

directed against the private and public specificities of the *H-2^k* haplotype. The results suggested that not only the private specificities of the *H-2K^k* gene, but also the public specificities that are known to be associated and present on the same molecule, are either missing or have greatly reduced expression on the K36 tumor cell. The *H-2D^k* gene products were present as expected. Non-cytotoxic antisera D23.b did not immunoprecipitate K36 glycoprotein in the mol wt range of histocompatibility antigens on electrophoresis. A precipitate in the 45,000-dalton range obtained by unabsorbed anti-*H-2.23* serum appeared not to be *H-2*. The results confirm the absence of the *H-2K^k* gene product from the cell surface of K36 and from detergent-solubilized tumor cells. (39 refs)

- 79-6478 Immunopotentiality Against the L1210 Leukemia by Pyran Copolymer and Crude Tumor Antigen. (Eng) Mohr, S. J. (Div. Urology, Univ. Colorado Medical Center, Denver, CO 80220); Chirigos, M. A. *Prog Cancer Res Ther* 7: 415-426; 1978.

The immunopotentiating properties of pyran in the L1210 tumor system were studied using adult male B6D2F₁, DBA/2, and CD2F₁ mice. Animals vaccinated with irradiated L1210 cells plus pyran copolymer showed significantly prolonged survival times after challenge with live L1210 cells, compared with controls vaccinated only with irradiated tumor cells. Significant immunity was present as early as 24 hr after pyran-vaccine treatment, and the protection afforded by this treatment appeared to be systemic. All three strains of mice responded well, although the hemisynthetic CD2F₁ mice showed the greatest response. The potentiating effect of pyran was also seen with other immunoadjuvants, such as BCG and glucan, and with all of the newly synthesized preparations of divinyl ether-maleic anhydride. However, the ability to potentiate immunity was not necessarily shared with all compounds possessing similar physical properties to pyran. When animals with established L1210 leukemia were treated with pyran, the drug proved to be only weakly therapeutic. However, pyran-vaccine treatment given 3 days after cytoreductive chemotherapy for established leukemia increased the survival time with chemotherapy alone by another 25%. (11 refs)

- 79-6479 Induction of Tumor Resistance in Mice By L1210 Leukemia Cells Persistently Infected with HVJ (Sendai Virus). (Eng) Takeyama, H. (Sloan-Kettering Inst. Cancer Res., New York, NY); Kawashima, K.; Yamada, K.; Ito, Y. *Gann* 70(4): 493-501; 1979.

The ability of L1210 leukemia cells persistently infected with HVJ (Sendai virus) to induce resistance against L1210 leukemia was studied using various inbred and hybrid mouse strains. L1210 cells infected with wild-type HVJ (L1210/c-HVJ-w cells) did not proliferate in growth medium and were damaged by HVJ-w. A paramyxovirus (HVJ-pi) from baby hamster kidney cells persistently infected with HVJ had no cytopathic effect on L1210/c cells, and L1210/c-HVJ-pi cells grew well in growth medium. Serially subcultured L1210/c-HVJ-pi cells carried viral antigens of HVJ. L1210/c-HVJ-w cells inoculated ip into DBA/2 or BDF₁ mice did not grow, whereas viable L1210/c-HVJ-pi cells showed a low degree of transplantability in normal syngeneic mice. The percentage of viral antigen-positive cells appeared to be inversely correlated with the growth of L1210/c-HVJ-pi cells in vivo. More than 90% of BDF₁ or CDF₁ mice immunized with 10⁵ L1210/c-HVJ-pi cells were protected against subsequent ip challenge with 10⁵ intact L1210/c cells. HVJ-pi or homogenized L1210/c cells offered no such protection. In the mice preimmunized with L1210/c-

HVJ-pi cells that died after tumor cell challenge, tumor development was markedly delayed. The induction of immune resistance was more prominent in (C57BL/6 x DBA/2)F₁ or (BALB/c x DBA/2)F₁ mice than in DBA/2 mice. Preimmunization with L1210/c-HVJ-pi cells did not protect against challenge with tumor other than L1210. (27 refs)

- 79-6480 Cell-Surface Characteristics of Hairy Cell Leukemia in Seven Patients. (Eng) Yanovich, S. (Dept. Tumor Immunology, Sidney Farber Cancer Inst., 44 Binney St., Boston, MA 02115); Marks, S. M.; Rosenthal, D. S.; Moloney, W. C.; Schlossman, S. F. *Cancer* 43(6): 2348-2351; 1979.

Surface marker studies were made of circulating peripheral blood hairy cells from seven patients with hairy cell leukemia (HCL). None of the patients had received chemotherapy. Sensitive analytic techniques, including specific antisera and the Fluorescence Activated Cell Sorter (FACS-1), were used to further define the abnormal cells. Four different antisera were used to investigate the cell-surface characteristics of these patients: (1) anti-p23,30, an antiserum reactive with B cells and a subset of monocytes; (2) anti-311, which reacts only with T cells; (3) pepsin-digested anti-F(ab')₂, which reacts only with B cells; and pepsin-digested antilysozyme, which is reactive with monocytes and myeloid cells but not with B or T cells. In all cases, strong reactivity was observed with anti-p23,30 and anti-F(ab')₂, but no reactivity was observed with anti-311. Five of the patients were reactive with antilysozyme in a pattern similar to that of normal monocytes. Furthermore, when cells were separated according to binding to anti-p23,30, anti-F(ab')₂, and anti-lysozyme and, in two cases, according to cell size, the majority of reactivity and large cells were "hairy" when examined under the microscope. In contrast, the small and nonreactive (dull cells) had the appearance of normal mature lymphocytes. Thus, the data support the view that HCL cells bear, in most cases, B-cell and monocytic membrane markers. (29 refs)

- 79-6481 Lipopolysaccharide Responsiveness of Malignant Lymphoid Cells in a Patient with Hairy Cell Leukemia. (Eng) Tatsumi, E. (First Div. Internal Medicine, Faculty Medicine, Kyoto Univ., Kyoto, Japan); Domae, N.; Takiuchi, Y.; Sawada, H.; Shirakawa, S.; Uchino, H. *Blood* 54(2): 524-529; 1979.

A positive response to lipopolysaccharide (LPS) by the malignant lymphoid cells of a 52-yr-old Japanese man with hairy cell leukemia (HCL) is reported. In medium supplemented with either fetal calf serum or human plasma, the cells showed a remarkable degree of stimulation by LPS 026:B6 and LPS 055:B5. The cells of normal individuals and individuals with other forms of leukemia showed a much lower degree of stimulation. The LPS-stimulated cells of the HCL patient showed a broadened and slightly basophilic cytoplasm, a dilated endoplasmic reticulum, and an increase in the number and the size of mitochondria; they were clearly distinct from unstimulated cells. (26 refs)

- 79-6482 Immunological Studies in Hairy Cell Leukemia. (Eng) Davey, F. R. (State Univ. New York, Upstate Medical Center, 750 E. Adams St., Syracuse, NY 13210); Dock, N. L.; Terzian, J.; Bala, R.; Gottlieb, A. J. *Arch Pathol Lab Med* 103(9): 433-436; 1979.

The results of cytochemical and immunological studies of tissues and mononuclear cell suspensions from 10 patients with hairy cell

leukemia are presented. In all cases studied, tartrate-resistant acid phosphatase was noted within the cytoplasm of the hairy cells (HC's). In two-thirds of the cases, α -naphthyl acetate esterase was observed in the HC's. In addition, HC's did not form spontaneous rosettes with sheep RBC. A variable number of HC's displayed complement receptors. The nonspecific binding of conjugated immunoglobulin (Ig) to HC's probably reflected the presence of a high concentration of Fc receptors on the surface of the HC's. In three cases, the conjugated Ig reacted predominantly to one light chain, suggesting the presence of a monoclonal Ig. In four of six cases, mononuclear cell suspensions of HC's demonstrated latex phagocytosis. In one case, HC's displayed resynthesis of surface membrane Ig, the presence of B-cell antigen, and phagocytosis of latex. These findings suggest that HC's are distinctive and contain properties of both B lymphocytes and monocytes. (32 refs)

- 79-6483 Definition of a Unique Cell Surface Antigen of Mouse Leukemia RL[Female]1 by Cell-mediated Cytotoxicity. (Eng) Nakayama, E. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Shiku, H.; Takahashi, T.; Oettgen, H. F.; Old, L. J. *Proc Natl Acad Sci USA* 76(7): 3486-3490; 1979.

The specificity of the cytotoxic T-cell response to the x-ray-induced BALB/c leukemia RL[female]1 [RL(f)1] was investigated. RL(f)1 is strongly immunogenic for (BALB/c x C57BL/6)F₁ mice. Transplants of RL(f)1 regressed after initial growth, and after tumor regression mice could resist repeated inocula of 10⁷ RL(f)1 cells. Spleen cells from immunized mice after in vitro stimulation with RL(f)1 were cytotoxic for RL(f)1 cells in 3-hr ⁵¹Cr assays. Pretreatment of immune spleen cells with Thy-1, Lyt-2, or Lyt-3 antisera and complement eliminated cytotoxic activity, indicating that effector cells for RL(f)1 lysis are T cells. Tests with other target cells showed little or no cytotoxicity. Analysis of the specificity of T-cell killing of RL(f)1 by competitive inhibition assays with unlabeled cells indicated that only RL(f)1 could inhibit killing. Other BALB/c tumors (13 x-ray or murine leukemia virus-induced leukemias and 3 myelomas) failed to inhibit lysis of RL(f)1. Various alloantisera and heteroantisera were tested for their capacity to block lytic activity in the absence of added complement. H-2^d antisera and Lyt-2 and -3 antisera blocked lysis, the latter at the level of the effector cell. Antisera to other cell-surface alloantigens, murine leukemia virus-related antigens, and immunoglobulins did not block RL(f)1 lysis. Thus, T cells from mice immunized against RL(f)1 recognize an individually distinct or unique antigen that does not appear to be related to any of the serologically defined cell-surface determinants of RL(f)1. In its restriction to a single leukemia, the RL(f)1 antigen resembles the individually distinct antigens of chemically induced tumors and other tumor types of rodents. (23 refs)

- 79-6484 Tumor Metastases and Cell-mediated Immunity in a Model System in DBA/2 Mice. VI. Similar Specificity Patterns of Protective Anti-Tumor Immunity In Vivo and of Cytolytic T Cells In Vitro. (Eng) Bosslet, K. (Institut für Immunologie und Genetik, Deutschen Krebsforschungszentrum, Heidelberg, W. Germany); Schirmacher, V.; Shantz, G. *Int J Cancer* 24(3): 303-313; 1979.

In an attempt to analyze mechanisms of immunity against tumor metastases, protective antitumor immunity in vivo was compared with cytotoxic T-cell activity in vitro in a well-defined syngeneic tumor model system. The system consisted of a chemically induced murine lymphoma (Eb) with little or no metastatic potential and its

spontaneous variant (ESb) with pronounced metastatic properties. Tumor protection experiments revealed the presence of tumor-associated transplantation antigens (TATAs) on both Eb and ESb tumor cells. TATAs of Eb and ESb were found to be distinct and did not cross react. One of several unrelated tumors, however, RL(male)1, expressed TATAs which cross-reacted with those of Eb. Protective immunity against the nonmetastasizing tumor was much stronger than that against the metastasizing variant. Striking differences were found in the optimal procedures for induction of in vivo immunity to each tumor. Tumor-specific cytotoxic T lymphocytes (CTLs) were obtained after sensitization in vivo with viable tumor cells and restimulation in vitro for 4-5 days with mitomycin-C-treated autologous tumor cells. Both anti-Eb and anti-ESb CTLs showed high cytolytic activity in a 4-hr ⁵¹Cr release assay against the autologous tumor lines. The target antigens recognized by these cells were similar to the TATAs as defined in the protection experiments (ie, distinct and non-cross-reactive). Only one of 14 unrelated syngeneic and allogeneic tumors expressed a target antigen which cross-reacted with that of Eb. This tumor was the radiation-induced BALB/c lymphoma RL(male)1 which also cross reacted at the level of the TATAs. The correlations between protective immunity obtained in vivo and cytolytic T cells induced in vitro suggest that cytolytic T cells can recognize TATAs and may thus play an important role in the establishment of protective immunity. (40 refs)

- 79-6485 Morphological Changes During Late Ontogenesis in Offspring of Mice with Induced Graft-vs-Host Reaction. (Rus) Fedosov, E. A. (Dept. Microbiology, Medical Inst., Smolensk, USSR); Zarudin, V. V. *Biull Eksp Biol Med* 88(7): 111-114; 1979.

A hypothesis concerning the existence of a direct relationship between disturbances of the immune system in mothers and the development of pathological changes of the immune system in their offspring was tested. Pregnant (CBA x C57BL/6)F₁ mice were inoculated with lymph node and spleen cells from normal C57BL/6 mice, and pregnant CBA mice were inoculated with cells (unspecified) from C57BL/6 donors immunized with spleen cells of CBA mice. The offspring of females with an induced graft-vs-host reaction were followed for 2 yr. Various malignancies were recorded in 18/62 of these offspring (compared with 1/24 controls). There were 11 lymphocytic neoplasms and 7 reticulocellular neoplasms. Tumorigenesis was associated with marked splenomegaly (up to 2-3 g) in eight mice and increased thymus wt (up to 90 mg, vs 20-30-mg in controls) in three mice. (17 refs)

- 79-6486 Opposing Tumorigenic and Immunogenic Properties of the In Vitro and the In Vivo Sublines of Moloney Induced Tumor. (Eng) Devens, B. (Dept. Immunology, Hebrew Univ.-Hadassah Medical Sch., Jerusalem, Israel); Galili, N.; Naor, D.; Klein, E. *Proc Leukocyte Cult Conf* (12): 707-714; 1979.

The tumorigenic and immunogenic properties of the in vitro (YAC-1) and in vivo (YAC) sublines of a Moloney virus-induced tumor carried in A mice were studied. Injection of one YAC cell into the peritoneal cavity of a normal syngeneic mouse resulted in death within about 7 wk. In contrast to the YAC tumor, the YAC-1 tumor showed remarkable immunogenic properties. The results of a co-target competition experiment indicated that the antigenic structure of the YAC tumor is different from that of the YAC-1 tumor, and that YAC-1 priming stimulates separate populations of effector cells to the two targets YAC and YAC-1. Spleen cells from A/J mice primed with the allogeneic Rauscher virus-induced RBL5

tumor of C57BL/6 mice cultivated for 6 days in vitro could generate cytotoxic responses against YAC and YAC-1 tumors. Spleen cells from A mice injected with YAC-1 or RBL5 cells could also generate a cytotoxic response against RBL5. The YAC tumor could not stimulate antitumor-reactive cells in A mice. It is concluded that the suppressor cells can discriminate between RBL5-primed cells and YAC-1-primed cells and exert their suppressive effect on cells that possess specificity to YAC-1 only. The antitumor reactivity induced by YAC-1 tumor could confer partial but significant antitumor resistance on A/J mice injected with low doses of viable tumor. (8 refs)

- 79-6487 Angioimmunoblastic Lymphadenopathy. Evolution to a Burkitt-like Lymphoma. (Eng) Mazur, E. M. (Dept Medicine, Yale Univ. Sch. Medicine, LC1 802, 333 Cedar St., New Haven, CT 06510); Lovett, D. H.; Enriquez, R. E.; Breg, W. R.; Papac, R. J. *Am J Med* 67(2): 317-324; 1979.

A primitive lymphoid neoplasm characterized by generalized lymphadenopathy, hepatosplenomegaly, and bone marrow and peripheral blood infiltration by lymphoid blast cells developed in a 64-yr-old woman with angioimmunoblastic lymphadenopathy of 1.5 yr duration. The blast cells demonstrated a high nuclear-cytoplasmic ratio, a deeply basophilic cytoplasm, and prominent cytoplasmic vacuoles, features similar to those described in both immunoblastic and Burkitt's cell leukemias. The clinical course resembled that of Burkitt's lymphoma, with markedly elevated serum lactate dehydrogenase levels that paralleled disease activity, hyperuricemia before therapy, and marked tumor sensitivity to the administration of cyclophosphamide, vincristine, cytosine arabinoside and prednisone that resulted in acute hyperkalemia, hyperphosphatemia and hypocalcemia. The patient died 3.5 mo after malignant transformation with leukemic meningitis. Cytogenetic studies of circulating blast cells revealed a distinctive translocation from the long arm of chromosome 8 to the long arm of chromosome 14 [46XX, t(8q-; 14q+)]. This karyotype has been correlated with Burkitt's lymphoma. The blast cells possessed no demonstrable B- or T-cell surface markers, nor did they transform to a continuous cell line in tissue culture. Antibody to Epstein-Barr viral capsid antigen was minimally increased at a titer of 1:80. No antibody to Epstein-Barr early antigen was present. This patient demonstrates the clinical, pathologic, and cytogenetic overlap among Burkitt's cell and immunoblastic leukemias and lymphomas. These disease processes appear to be part of a continuum in which this patient represents an intermediate form. (44 refs)

- 79-6488 Suppression of Cell-mediated Tumor Cell Lysis and Complement-induced Cytotoxicity by Trypan Blue. (Eng) Scornik, J. C. (Res. Service, Veterans Admin. Medical Center, Gainesville, FL 32602); Ruiz, P.; Hoffman, E. M. *J Immunol* 123(3): 1278-1284; 1979.

The effects of trypan blue (TB) on cell-mediated lysis (CML) of Ehrlich ascites tumor (EAT) cells and complement-induced cytotoxicity were studied. Different forms of CMC were suppressed in the presence of TB. The systems affected included antibody-coated EAT cells lysed by normal and *Corynebacterium parvum*-stimulated mouse peritoneal cells, and allogeneic targets lysed by immune effector cells. The inhibition, which was measured in a 4-hr ^{51}Cr -release assay, was reversible and did not occur in the presence of 30% fetal calf serum or albumin. Binding between effector and target cells through Fc receptors was unaffected, and lysis of allogeneic cells was inhibited at the lytic step rather than at the binding step. In contrast, lysis of sensitized RBCs was not inhibited by TB, suggesting that the lysis of these

targets may not involve the steps involved in tumor cell lysis. TB blocked the function of antibody before binding to target cells and also suppressed complement-induced cytolysis. Most individual complement components were susceptible to the inhibitory action of TB. These results reveal an affinity of TB for proteins that may be responsible for many of its biological actions. (30 refs)

- 79-6489 Lymphocyte Surface Membrane Immunoglobulin in Myeloma. I. M315-bearing T Lymphocytes in Mice with MOPC-315. (Eng) Gebel, H. M. (Dept. Pathology, Div. Biology and Biomedical Sciences, Washington Univ. Sch. Medicine, St. Louis, MO 63110); Hoover, R. G.; Lynch, R. G. *J Immunol* 123(3): 1110-1116; 1979.

Studies were conducted to determine whether the small M315 antibody-bearing mononuclear cells, which account for more than one-third of the circulating mononuclear cells in mice with 315/+ tumors, are myeloma cells or host lymphocytes. 315/+ is derived from the MOPC-315 plasmacytoma and differentiates from M315 producing, nonsecreting, lymphocytoid cells to large M315 secreting plasmacytoid cells. Experiments in CBF₁ mice demonstrated that the circulating M315-bearing cells were of F₁, rather than tumor origin. Serologic and ultrastructural studies demonstrated that the cells were post-thymic T lymphocytes. After proteolytic removal, surface M315 was re-expressed in vitro by 315/+ cells, but not by T cells. M315-bearing T cells accounted for 0% to 4% of circulating mononuclear cells in mice with 315/P, a variant of MOPC-315 in which all cells synthesize M315, but only 2% of the cells are secretory. There was no obvious relationship between the frequency of M315 bearing lymphocytes and development of the humoral immunodeficiency that accompanies myeloma. These findings (1) identify an association between high levels of M315 secretion and development of M315-bearing T cells; (2) favor the view that M315 is acquired, rather than produced by host T cells; and (3) raise the possibility that T cells with IgA-Fc receptors may be increased in mice with 315/+ tumors. (29 refs)

- 79-6490 Binding Constants of NZB Myeloma Antidextran for Dextran and Isomaltose Oligosaccharides Determined by Affinity Electrophoresis. (Eng) Sugii, S. (Dept. Microbiology, Columbia Univ., Coll. Physicians and Surgeons, New York, NY 10032); Takeo, K.; Kabat, E. A. *J Immunol* 123(3): 1162-1168; 1979.

The association constants of two NZB mouse myeloma antidextran, PC3858 and PC3936, were measured by affinity electrophoresis. With linear dextrans or with those with a low degree of branching, the association constants of dextrans ranged from 2.7×10^3 to 5.4×10^4 ml/g for PC3858 and from 1.3×10^4 to 2.6×10^5 ml/g for PC3936. Completely linear α -(1 \rightarrow 6)-linked dextrans, LD7 and D3, showed high affinities for the two NZB antidextran. The association constants of oligosaccharides (K_a) increased as the number of α -(1 \rightarrow 6)-linked glycosyl residues increased. Isomaltoheptaose (IM7) showed the highest K_a (1.9×10^4 M $^{-1}$ for PC3858 and 1.63×10^4 M $^{-1}$ for PC3936). Pullulan and glycogen showed very weak affinity for PC3936, but they did not react at all with PC3858. These findings indicate that NZB myeloma antidextran, PC3858 and PC3936, are specific for internal chains of α -(1 \rightarrow 6)-linked dextrans. (21 refs)

- 79-6491 Cloning of Immunoglobulin Kappa Light Chain Genes from Mouse Liver and Myeloma MOPC 173. (Eng) Steinmetz, M. (Institut fur Physiologische Chemie,

Physikalische Biochemie und Zellbiologie, Universität München, München, W. Germany; Zachau, H. G.; Mach, B. *Nucleic Acids Res* 6(10): 3213-3229; 1979.

The organization of the κ -chain constant-region gene was compared in DNA from an immunoglobulin-producing mouse myeloma (MOPC 173) and from BALB/c mouse liver. In situ hybridization using the Southern blotting technique revealed constant-region gene-containing EcoRI-DNA fragments of 14 and 20 kilobases (kb) in the myeloma tissue, whereas one EcoRI-DNA fragment with a length of 15 kb was found in liver DNA. After enrichment by RPC-5 chromatography and preparative electrophoresis, the 14-kb fragment from MOPC 173 DNA and the 15-kb fragment from liver DNA were cloned in the bacteriophage λ vector Charon 4A using in vitro packaging. Extensive characterization of the two fragments by restriction endonuclease mapping, in situ hybridization, and electron microscopy (R-loop and heteroduplex) showed that both contain the constant-region but no MOPC 173 variable-region gene. Both fragments are homologous over a length of 12.5 kb, including the constant region, but they differ from one another starting about 2.7 kb from the 5' end of the constant-region gene. This indicates that the 14-kb EcoRI-DNA fragment from the myeloma tissue clearly resulted from somatic DNA rearrangement, although it does not seem to carry the MOPC 173 variable-region gene. These observations suggest that somatic DNA rearrangement of immunoglobulin light-chain genes can involve both homologous chromosomes. (36 refs)

79-6492 Similarity of Casein- and Endotoxin-induced, Myeloma-associated and Aged SJL/J Amyloid in Various Strains of Mice. (Eng) Baumal, R. (Dept. Pathology, Univ. Toronto, Medical Sciences Bldg., Toronto, Ontario M5S 1A8, Canada). *Int Arch Allergy Appl Immunol* 59(1): 20-27; 1979.

Myeloma-associated amyloids of Balb/C mice, amyloids arising spontaneously in aged SJL/J mice, and amyloids induced by casein or endotoxin were compared. None of the amyloid preparations reacted with various anti-Ig antisera, but anti-casein and anti-myeloma amyloid antisera reacted with all three forms of amyloid. Analysis of the casein- and endotoxin-induced amyloids by electrophoresis revealed similar peaks of mol wt 12,000 in both cases. Similar results were obtained with the spontaneous amyloids, and it was concluded that all three forms existed as non-covalently bonded dimers. All three forms were also susceptible to potassium permanganate and oxalic acid, with or without trypsin digestion, as assessed by incubation of formalin-fixed, paraffin-embedded sections of amyloidotic spleens with these reagents prior to Congo-red staining. All forms of amyloid yielded similar peptide maps following digestion with trypsin and resolution on a Dowex column. Since the casein-induced murine amyloid resembles the nonimmunoglobulin form of human amyloid, it is concluded that an immunoglobulin form in mice has yet to be characterized. (20 refs)

79-6493 Immunologically Nonspecific Enhancement of Artificial Lung Metastases in Tumor-bearing Mice. (Eng) Ando, K. (Section Experimental Radiotherapy, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX 77030); Hunter, N.; Peters, L. J. *Cancer Immunol Immunother* 6(3): 151-156; 1979.

Enhancement of tumor growth in the lungs of tumor-bearing male C₃Hf/Bu mice inoculated iv with cells of the same syngeneic

transplantable fibrosarcoma (NFSA) was studied. Compared with untreated controls, mice bearing tumors for 14 days, but not less, developed significantly more lung colonies ($p < 0.01$). The number of lung colonies depended on the number of tumor cells injected, and spontaneous metastases were not the major reason for the enhancement. Mice showing enhanced lung tumor growth showed concomitant resistance to im tumor challenge. The tumor-induced enhancement disappeared shortly after surgical removal of the original tumors and was decreased relative to tumor-bearing controls even after subsequent iv tumor challenge. Whole-body γ irradiation (600 rad) and treatment of tumor-bearing mice with *Corynebacterium parvum* prior to iv tumor challenge prevented the enhancement phenomenon. Tumor-induced enhancement of lung colonies was also prevented by T-cell depletion (thymectomy followed by whole-body irradiation and bone-marrow reconstitution), but was not affected by adult thymectomy alone. Enhancement was not tumor-specific in that mice bearing another fibrosarcoma (FSA), which does not cross react immunologically with NFSA, also showed enhancement when challenged iv with NFSA. 79-6494 Cell-mediated Immune Response to Syngeneic UV-induced Tumors. IV. The Presence of I-A and I-E Subregion-coded Antigens on the Accessory Cell Required for the In Vitro Differentiation of Cytotoxic T Lymphocytes. (Eng) Woodward, J. G. (Dept. Pathology, Univ. Utah Medical Center, Salt Lake City, UT 84132); Daynes, R. A. *J Immunol* 123(3): 1227-1231; 1979.

The I-subregion-defined antigens present on the accessory cell required for the generation of antisynthetic tumor immunity were studied in mice, using the UV-induced C3H fibrosarcoma, RD-87. The removal of both anti-I-A and anti-I-E activity from anti-Iak serum by absorption was required to deplete cytotoxic activity against the accessory cells. Antisera specific for the A, B, and J subregions of the *k* haplotype as well as an antiserum specific for the J, E, or E, C subregions detected specificities present on both draining lymph node (DLN) accessory cells and splenic accessory cells. It was not possible to reduce accessory cell function with antisera specific for only J subregion-coded determinants. When antisera containing only the known specificities mapping in I-A or I-E were used, accessory cell function was eliminated from DLN cultures. When antisera specific for only Ia.7 of the *K* haplotype were used, accessory cell function was also eliminated. The data suggest that the accessory cell required for the in vitro generation of a tumor immune response expresses antigens that code in both the I-A and I-E subregions of the major histocompatibility complex. Ia.7 may be the important serologic specificity coding in the I-G subregion. Both A- and E-subregion-coded determinants appear to be expressed on the same population of accessory cells. (21 refs)

79-6495 Specific Triggering of Macrophage Accumulation at the Site of Secondary Tumor Challenge in Mice with Concomitant Tumor Immunity. (Eng) Hopper, K. E. (Kolling Inst. Medical Res., Royal North Shore Hosp. of Sydney, St. Leonards, New South Wales 2065, Australia); Nelson, D. S. *Cell Immunol* 47(1): 163-169; 1979.

The peritoneal cellular response to tumor challenge was studied in CBA/J mice bearing sc isografts of syngeneic 3-methylcholanthrene-induced fibrosarcoma C-4 or C-15. In mice bearing C-4 isografts for 7 days and challenged ip with C-4, but not in those challenged with C-15, there was a significant increase in peritoneal macrophages. The macrophage counts in mice bearing

C-4 tumors for 14 days were significantly raised after ip challenge with either C-4 or C-15. Peritoneal macrophage numbers were also significantly elevated in normal mice injected ip with C-4 cells plus peritoneal cells from mice bearing C-4 tumor for 7 days as compared with normal mice injected with C-4 cells only or C-4 cells plus peritoneal cells from non-tumor-bearing mice. The new population of peritoneal cells were young monocyte-derived macrophages as determined by their morphology, position, sedimentation velocity profiles, chemotaxis, and labeling in vivo following [^3H]thymidine injection. The data suggest that the expression of immunity to some methylcholanthrene-induced fibrosarcomas involves reactions akin to delayed-type hypersensitivity in which an immunologically specific reaction triggers the delivery of nonspecific effector cells to the site of tumor challenge. (7 refs)

- 79-6496 **Passive Enhancement of Mouse Tumor Allografts by Alloantibodies is Fc-Dependent.** (Eng) De Waal, R. M. (Dept. Pathology, Univ. Nijmegen, Geert Grooteplein Zuid 24, 6500 HB Nijmegen, Netherlands); Cornelissen, I. M.; Capel, P. J.; Koene, R. A. *J Immunol* 123(3): 1353-1355; 1979.

The role of the Fc and F(ab')₂ antibody fragments in the enhancement of mouse tumor allograft growth following the injection of alloantisera against donor transplantation antigens in tumor-bearing recipients was investigated. The tumor used was a mouse fibrosarcoma induced in a B10.D2 female mouse by sc injection of methylcholanthrene. A suspension of tumor cells (2×10^6) was injected intracutaneously in female B6AF₁ recipients, and tumor growth was followed macroscopically. Enhancement of tumor growth was induced by ip injections of alloantiserum on days 0, 2, and 4 after transplantation. No macroscopically detectable tumor growth occurred without treatment with an enhancing antiserum. Dose-response studies with intact IgG showed that the threshold dose for induction of enhancement by IgG was 300-960 μg . F(ab')₂ in a dose of 2,200 μg was ineffective. Multiple daily injections of F(ab')₂ (1,000 $\mu\text{g} \times 2$ on day 0; $\times 3$ on day 1, 2, 3, 4, and 5) were also ineffective (0/10 mice with growing tumors). These data indicate that administration of F(ab')₂ fragments of alloantibodies to recipients of mouse tumor allografts does not result in enhancement of tumor growth. This finding is contrary to other reports, which may be explained by contamination with undigested IgG. It is concluded that the Fc part of the alloantibody molecule is required for the induction of enhancement of mouse tumor allografts. (21 refs)

- 79-6497 **Competition Between Foetal Tissue and Macrophage-dependent Natural Tumour Resistance.** (Eng) Keller, R. (Immunobiology Res. Group, Inst. Medical Microbiology, Univ. Zurich, Zurich, Switzerland). *Br J Cancer* 40(3): 417-423; 1979.

Competition between fetal liver cells and macrophage-dependent natural cytotoxicity was studied in vitro, and the enhancement of tumor growth by irradiated fetal liver cells was demonstrated. Prolonged interaction between *Corynebacterium parvum*-induced adherent phagocytic peritoneal cells and syngeneic or xenogeneic tumor targets consistently produced marked cytotoxicity. In the presence of irradiated (2,000 rad) liver cells from 14- to 16-day-old syngeneic (DA rat) or allogeneic (Zbz:Car) embryos, this spontaneous cytotoxicity against various target cells was blocked in a dose-dependent manner. Irradiated liver cells from adult donors manifested no such competition with tumor targets. The ability of irradiated liver cells to compete with tumor targets such as DMBA-

12, Py-12, or P-815 cells was progressively and rapidly lost after birth as indicated with assays using liver cells obtained on day 1, 3, or 5 after birth. Inoculation of 7,12-dimethylbenz(a)anthracene (DMBA)-induced syngeneic ascites tumor cells (DMBA-12: 10^7 cells, ip) into DA rats consistently resulted in progressive tumor growth. The inoculation of 10^6 - 10^7 irradiated syngeneic (or allogeneic) fetal liver cells 1 day before tumor cell challenge promoted tumor growth. Irradiated liver cells from adult donors had no such effect. Tumor growth promotion by fetal liver cells was consistently marked in rats >9 mo old, but was less pronounced in younger rats. Tumor growth was markedly enhanced when irradiated fetal cells were administered either shortly before or after tumor cell inoculation. These findings are consistent with a role for nonspecific immunity in tumor resistance and underline the critical nature of the initial phase of tumor nidation. (24 refs)

- 79-6498 **Recognition of RSV-induced Tumor Cells in Syngeneic Mice and Semisyngeneic Reciprocal Hybrid Mice.** (Eng) Yoshida, T. O. (Dept. Microbiology, Hamamatsu Univ. Sch. Medicine, Handa-cho 3600, Hamamatsu 431-31, Japan); Haraguchi, S.; Miyamoto, H.; Matsuo, T. *Gann Monogr Cancer Res* 23: 201-212; 1979.

The immunogenetic control of the growth of virus nonproducing tumor cells induced by Schmidt-Ruppin strain of Rous sarcoma virus in inbred mice was investigated in syngeneic, F₁ hybrid semisyngeneic and H-2 identical allogeneic mice. The data on recognition (blastogenesis) in vitro and the resistance (transplantability, survival period, and injection) of F₁ hybrid semisyngeneic mice against BALB/cCr sarcoma cells C-SA-1M (derived from male mouse) and C-SA-9F (derived from female mouse) suggested that reciprocal semisyngeneic mice, H-2(d/k), (C \times C3)F₁, (C \times B10BR)F₁; H-2(k/d), (C3 \times C)F₁, (B10BR \times C)F₁; H-2(d/b), CBF₁; H-2(b/d), BCF₁, showed high resistance; H-2(d/a), (C \times B10A)F₁ showed a moderate resistance; and H-2d/d, CDF₁, DCF₁, (C \times B10D2)F₁, (B10D2 \times C)F₁, showed a low resistance. Further evidence in reciprocal F₁ hybrid mice suggested that even if reciprocal semisyngeneic F₁ hybrid mice are the same at gene level, the phenotypic resistance of the mice to the transplantation of parental tumor cells is markedly different. This phenomenon may be related to maternal inheritance. The role of H-Y antigen on the surface of tumor cells in relation to the immunological xenogenization of tumor cells may prove to be a very important factor. (26 refs)

- 79-6499 **Induction of Sarcomas in Nude Mice by Implantation of Syrian Hamster Fetal Cells Exposed In Vitro to Nickel Subsulfide.** (Eng) Costa, M. (Dept. Medical Pharmacology and Toxicology, Texas A&M Univ. Coll. Medicine, College Station, TX 77843); Nye, J. S.; Sunderman, F. W.; Allpass, P. R.; Gondos, B. *Cancer Res* 39(9): 3591-3597; 1979.

Athymic (nude) mice were used to evaluate the tumorigenicity of Syrian hamster fetal cells that had been exposed to nickel subsulfide. In vitro exposure of the cells to $\alpha\text{Ni}_3\text{S}_2$ yielded positive colony assays for morphological transformation. A dose-response relationship was found between the concentration of $\alpha\text{Ni}_3\text{S}_2$ and the incidence of morphological transformation. Exposures to $\alpha\text{Ni}_3\text{S}_2$ induced morphological transformation at concentrations (0.1 or 1.0 $\mu\text{g}/\text{ml}$ culture medium) that did not impair cell plating efficiency. Nickel monosulfide did not induce morphological transformation of the fetal cells under the same conditions. Clones of $\alpha\text{Ni}_3\text{S}_2$ -transformed cells were able to grow in soft agar medium, and they demonstrated increased basal and induced activities of ornithine decarboxylase. Undifferentiated sarcomas

developed in 26/27 nude mice at the site of sc injection of clones of $\alpha\text{Ni}_3\text{S}_2$ -transformed cells. No tumors developed in 19 control nude mice that were given sc injections of nontransformed fetal cells that had not been exposed to $\alpha\text{Ni}_3\text{S}_2$. Thus, fetal cells that undergo transformation following exposure to $\alpha\text{Ni}_3\text{S}_2$ are capable of producing malignant tumors in nude mice. (47 refs)

- 79-6500 Action of Complement in the Lysis of Mouse Sarcoma Cells Sensitized with H-2 alloantibody. (Eng) Reske-Kunz, A. B. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Scheid, M. P.; Abbott, J.; Metakis, L. J.; Polley, M. J.; Boyse, E. A. *Transplantation* 28(2): 149-153; 1979.

Sequential steps in complement binding and activation and their effects on nucleated cell lysis were studied using a modified cytotoxicity assay in which complement components were added in sequence to antibody-sensitized cells. The assay was applied to a model system in which mouse sarcoma cells were sensitized with H-2 alloantibody. The concentration of C1 giving optimal lysis in the nucleated cell system was $50 \mu\text{l}$ per 5×10^6 cells. With iodine-oxidized whole human serum (^{125}I -HS) at 1:40, C4 inhibited the lysis of Meth A cells by H-2 antibody at concentrations $>4 \mu\text{g}$, and max cytolysis was obtained without the addition of C4, indicating that ^{125}I -HS contained enough C4 for optimal lysis. The time of max formation of EAC142 (tmax) in the Meth A system was longer than tmax in the classical reaction sequence in erythrocytolysis, and an approx twofold increase in lytic activity was achieved by incubating sensitized cells complexed with C1 and C4 (TAC14) with ^{125}I -HS or ^{125}I -C2 for 60 min rather than 11 min. ^{125}I -HS in the modified assay was 20-fold more active than guinea pig serum and HS in the conventional assay, and approx 1.5-fold more active than rabbit serum. The activity of ^{125}I -HS was 6.3-fold greater than PO_4 -HS and 4-fold more active than HS when each serum was incubated for its respective tmax. The antiserum-specific lysis of Meth A tumor cells appeared to be mediated to some extent by the alternative pathway alone, and C2-deficient HS appeared to contain heteroantibodies capable of activating the alternative pathway and leading to cytolysis. The data may suggest that multiple complement-mediated functional lesions are necessary for immune lysis of nucleated cells. (26 refs)

- 79-6501 Age-related and Thymus-dependent Rejection of Adenovirus 2-transformed Cell Tumors in the Syrian Hamster. (Eng) Cook, J. L. (Natl. Inst. Allergy and Infectious Disease, NIH, Bethesda, MD 20205); Lewis, A. M.; Kirkpatrick, C. H. *Cancer Res* 39(9): 3335-3340; 1979.

The age-related and thymus dependent rejection of adenovirus 2 (Ad2)-transformed cell tumors in Syrian hamsters was investigated. Ad2-transformed hamster cell-induced newborn tumor lines were usually rejected when transplanted sc into 21-day-old syngeneic, weanling hamsters. The tumor-inducing capacity of two of these lines (Ad2HTL3 and Ad2HTL6) was tested in intact and neonatally thymectomized hosts. After sc injection of suspensions prepared from these lines, none of the weanling hamsters developed tumors, but 100% of the newborns and 35.2% of neonatally thymectomized, weanling hamsters developed progressively enlarging neoplasms. The susceptibility of neonatally thymectomized hamsters to tumor challenge was directly related to the degree of immunosuppression observed following thymectomy, as indicated by the amplitude of the in vitro response of blood WBC to concanavalin A. Pretreatment of thymectomized weanlings with syngeneic adult lymphoid cells (ip) resulted in a significant reduction in tumor susceptibility ($p = 0.03$). These findings

suggest that acquisition of resistance to Ad2-transformed cells during the first 21 days of life may be a thymus-dependent cellular immune process. (24 refs)

- 79-6502 Rejection of Tumor Cells In Vitro: Morphological Studies on Killer T Cells and Damaged Tumor Cells. (Eng) Berczi, I. (Dept. Immunology, Faculty Medicine, Univ. Manitoba, Winnipeg, Manitoba, Canada); Kovacs, K.; Horvath, E.; Sehon, A. H. *Int Arch Allergy Appl Immunol* 59(1): 1-12; 1979.

The in vitro destruction of methylcholanthrene-induced guinea pig sarcoma (MC-D) by killer T lymphocytes was studied using light and electron microscopy. Killer lymphoblasts (LBC) usually emerged between days 5 and 7 and destroyed the MC-D monolayer within 48-72 hr. The LBC were extremely mobile and, once all the MC-D cells were killed, floated freely in the supernatant, stopped proliferating, and gradually lost their viability. Some of the LBC remained viable for up to 3 wk, and upon restimulation achieved by adding MC-D target cells, they started to proliferate. The LBC closely resembled antibody-forming plasma cells but lacked the extensive network of rough endoplasmic reticulum (RER) and did not produce immunoglobulin. In MC-D cells with slight LBC-induced injury, dilatation, vesiculation, fragmentation, and degeneration of the RER were the most characteristic findings. In cells with extensive injury, widespread nuclear and cytoplasmic alterations were evident; and many of these cells were fragmented into smaller portions and finally transformed into granular membranous and amorphous debris. Many cells contained mature and immature particles resembling C-type viruses. These particles were detected in both intact and injured cells. It is suggested that the LBC cells are end cells similar to those of B lymphocyte-derived plasma cells and that the virus particles observed became activated during the interaction of LBC with MC-D. (36 refs)

- 79-6503 Immunocytochemical Studies of Human Myeloma Cells by Light and Electron Microscopy. (Eng) Biberfeld, P. (Dept. Pathology, Karolinska Inst., Stockholm, Sweden); Mellstedt, H.; Pettersson, D. *Isr J Med Sci* 15(8): 687-692; 1979.

Monoclonal cells from the blood of myeloma patients were studied using immunocytochemical techniques. The presence of various numbers of lymphoid cells expressing myeloma protein determinants on their surface was consistently demonstrated. The relative number of these surface idiotype-positive cells (sld+) varied from 3%-45% before treatment to 0% or slightly more during remission; during relapse and the terminal stages of the disease, the number increased to up to 60%-70%. The idiotype determinants were of endogenous and monoclonal origin, and they expressed only one type of light chain. In general, the number of cells stainable for intracellular immunoglobulin paralleled the number stainable for myeloma protein. Only 4/15 patients had demonstrable cytoplasmic immunoglobulin in their monoclonal, circulating cells; these myelomas were cytologically the most well differentiated. Both immunocytochemical and ultrastructural observations indicated various morphological types of myeloma cells ranging from lymphoid cytology to definite plasmacytoid differentiation. However, most patients showed some lymphoidlike myeloma cells in their blood. Monitoring the blood levels of idiotype-positive and immunoglobulin-positive cells appears to be a sensitive probe for following the development of human myeloma. (11 refs)

79-6504 Partial Characterization of an Antigen from a Human Myeloma Cell and Its Reactivity with an Anti-myeloma Cell Serum. (Eng) Krueger, R. G. (Lab. Molecular Oncology, Christ Hosp. Inst. Medical Res., 2141 Auburn Ave., Cincinnati, OH 45219); Hilton, P. *Int J Cancer* 24(2): 134-140; 1979.

The antibody specificity of a rabbit antiserum generated to the RPMI 8226 line of human myeloma cells was studied and the antigen was isolated and characterized. In a quantitative semimicro complement fixation assay, the antiserum reacted to a significantly higher titer with RPMI 8226 cells than with RPMI 4098 human lymphocytes or normal human bone marrow cells, particularly after absorption with RPMI 4098 cells. A similar difference in reactivity was noted for cell-free lysates of the three different cell types. Of various solubilization procedures used, deoxycholate treatment of sonicated or freeze-thaw extracts, 3 M KCl, autolysis, and papain digestion solubilized antigens from RPMI 8226 cells that reacted with anti-RPMI 8226 cell serum absorbed with RPMI 4098 cells. The solubilized RPMI 8226 cell antigens did not react with an antiserum to RPMI 4098 cells. Components solubilized from RPMI 4098 cells by similar procedures did not react with the absorbed anti-RPMI 8226 cell serum to a significant extent. The material solubilized from the RPMI 8226 cells consisted of three proteins with approx mol wts of 66,000, 55,000, and 31,000 daltons, as estimated by acrylamide gel electrophoresis. The results indicate that the RPMI 8226 cell line possesses antigens not found on the RPMI 4098 line, that these antigens can be solubilized, and that they react with an antiserum generated to intact RPMI 8226 cells. (17 refs)

79-6505 Receptor Sites for Complement and for Immune Complexes on Human Nonhemopoietic Tumor Cells. (Eng) Biran, H. (Dept. Development Therapeutics, M. D. Anderson Hosp. and Tumor Inst., Univ. Texas System Cancer Center, 6723 Bertner Ave., Houston, TX 77030); Mavligit, G. M.; Moake, J. L. *Cancer* 44(1): 131-135; 1979.

Primary cultures of tumor cells derived from 11 untreated nonhematopoietic cancer patients were reacted with specifically coated sheep erythrocytes (E's). Rosette formation between tumor and indicator cells was assessed. Eight of the primary cultures reacted positively with both IgG-coated (EA_{I_gG}) and with IgM-human complement-coated (EA_{I_gM}C or EA_{I_gM}C 4,3) sheep E's. EA_{I_gG} rosette formation in positive cultures ranged from 25% to 85%, and for EA_{I_gM}C/EA_{I_gM}C 4,3, reactivity ranged between 22% and 95%. Rosette formation with E (uncoated) and EA_{I_gM} was negligible. These findings suggest that human nonhematopoietic tumor cells may carry on their surface receptor sites for an IgG component of immune complexes and for human complement. These receptor sites may be important in the host-tumor relationship. (33 refs)

79-6506 Histocompatibility Antigens in Patients with Hepatocellular Carcinoma and Their Relationship to Chronic Hepatitis B Virus Infection in These Patients. (Eng) Kew, M. C. (Dept. Medicine, Univ. Witwatersrand Medical Sch., Hospital Hill, Johannesburg, South Africa 2001); Gear, A. J.; Baumgarten, I.; Dusheiko, G. M.; Maier, G. *Gastroenterology* 77(3): 537-539; 1979.

Forty histocompatibility antigens (HLA) of 102 South African blacks with histologically confirmed hepatocellular carcinoma (HCC) were compared with those of 208 healthy controls using a standard two-stage lymphocyte microcytotoxicity assay. The fre-

quencies of only three antigens (HLA-A1, HLA-A W36, and HLA-B7) differed significantly between HCC patients and controls, and these differences were not significant when the data were corrected for the total number of antigens tested. The frequency of HLA antigens did not differ significantly between 50 patients positive for hepatitis B surface antigen (HBsAg) and 50 HBsAg-negative patients. Of 92 patients tested, 88% were positive for antibody against hepatitis B core antigen (anti-HBc). The pattern of HLA antigens in these patients did not appear to differ significantly from that in anti-HBc-negative patients. The data show no evidence of a genetic predisposition to either hepatocellular carcinoma or to chronic hepatitis B surface antigenemia in patients with HCC. (14 refs)

79-6507 Activity of Syngeneic Complement for Revealing Antibody-induced Cytotoxicity Against a Rat Hepatoma. (Eng) Price, M. R. (Cancer Res. Campaign Lab., Univ. Nottingham, University Park, Nottingham NG7 2RD, England); Hoffken, K.; Baldwin, R. W. *Transplantation* 28(2): 140-143; 1979.

The cytotoxicity of tumor-bearer serum against a transplanted aminoazodye-induced rat hepatoma (D23) was studied using normal WAB/Not rat serum as the source of complement and a short-term ⁵¹Cr release test. Hepatoma D23-bearer serum displayed complement-dependent cytotoxicity for hepatoma D23 cells, and both normal and tumor-bearer rat serum contained the appropriate and sufficient complement components required to mediate antibody lysis in vitro. Treatment of rats with normal rat serum or heat-inactivated normal rat serum following an sc challenge of 10³ D23 cells had no effect on the incidence of sc tumors. Similar results were obtained when the D23 cells were injected into the peritoneal cavity. However, when unheated sera were used in similar tests and an incubation of 2 hr was performed prior to injection, the cytotoxic action of the tumor-bearer serum was demonstrated. These findings indicate that tumor-specific complement-dependent cytotoxicity of tumor-bearer serum against syngeneic rat hepatoma cells occurs when rat serum is used as the source of complement. That the tumor-bearing rat contains both antibody and complement sufficient for tumor lysis suggests that this may impose some immunological control upon the survival of cells released from the developing tumor. (21 refs)

79-6508 The Nude Mouse as a Tissue Amplifier for Studies of Experimental and Human Pancreas Cancer. (Eng) Fitzgerald, P. J. (Dept. Pathology, Memorial Sloan-Kettering Cancer Center, New York, NY); Sharkey, F. E.; Fogh, J.; Varricchio, F.; Cubilla, A.; Pour, P. In: *The Nude Mouse in Experimental and Clinical Research*. Fogh, J.; Giovanella, B. C., eds. (New York: Academic Press): 502 pp.; 267-279; 1978.

The use of the nude mouse as a tissue amplifier for studies of experimental and human pancreatic cancer was studied. A human duct cell adenocarcinoma, a nitrosamine-induced hamster duct adenocarcinoma, and a rat azaserine-induced acinar cell carcinoma were transplanted into nude mice and maintained over a few generations. Of the three tumors, the acinar cell tumor grew the fastest. With regard to the human pancreatic tumors, the shorter the time between removal of the tissue and its transplantation, the greater the chance of growth in the nude mouse. Three of five rat tumors grew in the nude mouse, and the hamster tumor grew in 1/4 mice. All three tumor types retained the general morphological appearance of the original tumor, although there was a tendency for the adenocarcinomas to become more glandular. The

original hamster tumor did not appear to be malignant, but the mouse transplant was malignant. The presence of a relatively high concentration of amylase in the acinar cell cancer and its absence in the duct cell cancers were in keeping with their origins. The observed relative decrease in the H1^o histone in the rat acinar cell carcinoma was associated with the focal anaplasia of this tumor. The nude mouse provides a means whereby large amounts of tumor tissue can be harvested for biochemical, immunologic, and morphologic studies. (13 refs)

- 79-6509 Temperature-dependent Alteration in Immunogenicity of Tumor-associated Transplantation Antigen Monitored via Paraformaldehyde Fixation. (Eng) Oikawa, T. (Lab. Pathology, Cancer Inst., Hokkaido Univ., Sch. Medicine, Sapporo 060, Japan); Gotohda, E.; Austin, F. C.; Takeichi, N.; Boone, C. W. *Cancer Res* 39(9): 3519-3523; 1979.

Paraformaldehyde-fixed mKSA tumor cells, a simian virus 40-transformed BALB/c kidney cell line, were shown to retain tumor-associated transplantation antigen (TATA) activity to a degree comparable to that of x-ray-inactivated tumor cells under the optimal conditions of 1% paraformaldehyde for 30 min at 37 C. Unexpectedly, the TATA activity of cells fixed below 10 C was greatly reduced. This temperature effect was reversible. TATA activity was restored if the cells were returned to 37 C before fixation. Fixation at all temperatures for >2 hr or at paraformaldehyde concentrations >1% also caused a decrease in immunogenicity. In the Winn assay, spleen cells from mice immunized with tumor cells fixed at 37 C were able to neutralize tumor growth more effectively than those from mice immunized with cells fixed at 0 C. Immunization with paraformaldehyde-fixed tumor cells was completely specific. Mice immunized with an antigenically unrelated tumor were not rendered immune to tumor challenge. Fixed tumor cells could be stored for at least 1 mo without loss of TATA activity. (30 refs)

- 79-6510 HLA System in Wilms' Tumor of the Kidneys and in Neuroblastoma. (Cze) Abrahamova, J. (Onkologicka klinika, Fakulta vseobecneho lekarstvi KU, U nemocnice 2, 128 08 Prague 2, Czechoslovakia); Majsky, A.; Koutecky, J. *Cesk Pediatr* 34(5): 268-270; 1979.

Twenty-three HLA antigens of loci A and B were detected in lymphocytes of 46 children (24 boys and men, 12 girls and women; aged 1-24 yr) with Wilms' tumor and in those of 20 patients (9 boys and men, 11 girls and women, aged 1-24 yr) with neuroblastoma. Three hundred and one healthy subjects served as controls. The frequencies of HLA-A1 and A9 were increased in the patients with Wilms' tumor (45.65% and 36.95%, respectively, vs 28.24% and 19.27% in controls). The incidence of the HLA-B₁₃ and Bw₂₁ antigens was increased in patients with neuroblastoma (25% and 15%, respectively), compared with controls (8.98% and 4.65%, respectively). (5 refs)

- 79-6511 The Immune Reactivity of Patients with Cancer of the Esophagus. (Ita) Ancona, E. (Istituto di Patologia Chirurgica III, Universita degli Studi di Padova, Padua, Italy); Amadori, G.; Ninfo, V.; Bardini, R.; Semenzato, G.; Gasparotto, G.; Peracchia, A. *Minerva Med* 70(23): 2311-2320; 1979.

The immune reactivity of 50 patients with various stages of epidermoid cancer of the esophagus was evaluated in several tests. In general, erythrocyte (E)-rosette formation and the lymphocyte response to phytohemagglutinin were significantly depressed in the

patients compared with controls. However, the responses of individual patients varied. (56 refs)

- 79-6512 Carcinoembryonic Antigen (CEA) in the Gastric Mucosa After Partial Gastrectomy. (Eng) Janunger, K. G. (Dept. Surgery, Univ. Hosp., Umea, Sweden); Lindgren, J.; Sipponen, P.; Domellof, L. *Scand J Gastroenterol* 14(5): 555-560; 1979.

Carcinoembryonic antigen (CEA) was studied by the three-layer bridge immunoperoxidase technique in gastric biopsy specimens taken from 49 patients, 13-20 yr after partial gastrectomy. Routine histological examination revealed various degrees of chronic atrophic gastritis in all patients. A positive CEA reaction was found in 6/9 patients with malignant or premalignant mucosal changes and in 4/40 without these changes. In two cases of carcinoma the biopsies revealed a positive CEA reaction. Of 4 patients with carcinoma diagnosed 1-2 yr after the first examination the initial nonmalignant biopsies were CEA-positive in one case. All biopsies from mucosa with severe dysplasia and adenomatous polyps were CEA-positive. Four patients without malignant or premalignant changes in the gastric mucosa had CEA-positive biopsies. No carcinoma has been found in these patients at re-examinations after 1 yr. The results indicate that the occurrence of immunohistochemically detectable CEA in the gastric mucosa may be associated with malignant transformation. (32 refs)

- 79-6513 Lysis of Allogeneic Tissue Cultured Colorectal Cancer Cells by Blood Group Isoantibody in Normal Human Serum. (Eng) Cohen, A. M. (Cox Cancer Center, Massachusetts General Hosp., Boston, MA 02114); Wood, W. C. *J Surg Res* 27(1): 1-7; 1979.

Established tissue culture colorectal cancer lines were evaluated for the presence of cell-surface blood group isoantigen activity. Four tumor cell lines obtained from donors of blood groups A or AB were used as targets in complement-dependent cytotoxic antibody and mixed hemagglutination assays. The presence of cell-surface isoantigen A-like activity was demonstrated on these lines by a micromixed hemagglutination reaction. The majority of sera obtained from type O normal donors was cytotoxic. The B sera were less frequently reactive. Despite the presence of isoantigen B-like activity on one cell line, sera from normal A donors were not reactive. Human serum was an adequate source of complement in these reactions. The specificity of these reactions was confirmed by RBC absorption experiments. Blood group isoantigen activity represents another area of potential confusion in the study of human tumor cell-surface antigens using allogeneic colorectal cancer cells. (28 refs)

- 79-6514 Analysis of the Expression of H-2 and H-2-linked Antigens on Mammary Tumor Cells. (Eng) Snoek, M. (Div. Genetics, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Amsterdam, Netherlands); Demant, P. *Int J Cancer* 24(2): 165-167; 1979.

The products of the recently discovered H-2L locus were expressed on BALB/c mammary tumor cells and behaved as histocompatibility antigens, in contrast to the products of H-2-linked loci (Qa loci), which did not influence the acceptance or rejection of tumor transplants in syngeneic and allogeneic recipients. (19 refs)

- 79-6515 Lack of Relationship of Transplantation Immunogenicity in C3H/He Mammary Carcinomas,

with Lymphoid Hyperplasia and Radiation-induced Growth Enhancement. (Eng) Vaage, J. (Dept. Cancer Therapy Development, Pondsby Hosp., Walpole, MA 02081). *Cancer Immunol Immunother* 6(3): 185-189; 1979.

Lymphoid hyperplasia during the progressive growth of three syngeneic C3H/He mammary carcinomas (immunogenic MC31-1B, growth-stimulating MC31-5B, and neutral MC31-7B) in female C3H/He mice was studied. After sc implantation, all three mammary carcinomas (MC) caused lymphoid hyperplasia in the hosts, as did sc pieces of autochthonous or syngeneic normal liver or kidney; sterile styrofoam implants had no effect. All three MC grew significantly better in irradiated (300 rad total-body irradiation 2 days before challenge) mice than in normal hosts. The spleen was consistently smaller in irradiated than in nonirradiated hosts. On the basis of these observations, it is concluded that neither lymphoid hyperplasia in normal hosts nor growth enhancement in immunosuppressed hosts is a reliable in vivo test for tumor-specific transplantation immunogens. (12 refs)

79-6516 Inhibition of Lymphocyte Function in Rats Fed High-Fat Diets. (Eng) Kollmorgen, G. M. (Cancer Res. Program, Oklahoma Medical Res. Foundation, Oklahoma City, OK 73104); Sansing, W. A.; Lehman, A. A.; Fischer, G.; Longley, R. E.; Alexander, S. S.; King, M. M.; McCay, P. B. *Cancer Res* 39(9): 3458-3462; 1979.

The effects of high-fat diets [20 g polyunsaturated fat (PSF) or saturated fat (SF) per 100 g of feed] on lymphocyte function were studied in female outbred Sprague-Dawley rats. 7,12-Dimethylbenz(a)anthracene (DMBA) was given via a stomach tube as a single 10-mg dose. The mammary tumor incidence after DMBA was significantly lower in rats on the SF diet than in those on the PSF diet or the control low-fat (LF) diet. Lymphocytes from rats on the LF diet showed a comparable blastogenic response when grown in autologous serum, allogeneic serum from rats on the LF diet (ASLF), or horse serum. A significantly lower response was observed when these lymphocytes were grown in serum from rats on the PSF diet. Lymphocytes from rats on the PSF diet showed a significantly lower blastogenic response in serum when compared with those from rats on the LF diet. Lymphocytes from the PSF rats showed a significantly higher response when grown in horse serum or ASLF than when grown in serum or allogeneic serum from PSF rats. Serum deficiency was not responsible for these observations, and it was concluded that blastogenesis was inhibited by one or more serum factors. Lipoprotein-free serum from rats on the LF diet did not inhibit the blastogenic response of LF lymphocytes, but significant inhibition was associated with the lipoprotein fraction. In contrast, lipoprotein-free serum from rats on the PSF diet did inhibit the blastogenic response; and very severe inhibition was observed when the lipoprotein fraction from this serum was evaluated. (32 refs)

79-6517 Immunity to the T1699 Murine Mammary Tumor. II. Thymic Influence on the In Situ Inflammatory Response, Metastatic Growth and Invasiveness. (Eng) Parthenais, E. (Transplantation Lab., Univ. Helsinki, Haartmaninkatu 3A, SF 00290 Helsinki 29, Finland); Haskill, S. *J Immunol* 123(3): 1334-1338; 1979.

The influence of cellular vs humoral immunity on the syngeneic mammary adenocarcinoma T1699 was investigated using adult thymectomized, lethally irradiated, bone-marrow-repopulated (ATXBM) and nonthymectomized, irradiated-repopulated, (CXBM) DBA/2 female mice. Tumors were induced by sc injection of

T1699 tissue culture tumor cells in the abdominal area. Median survival time for ATXBM tumor bearers was 38 days, compared with 86 and 91 days for CXBM and nonirradiated tumor bearers, respectively. At 14 days after tumor cell injection, the number of in situ monocyte-macrophages, eosinophils, and lymphocytes was markedly reduced, whereas neutrophils were more numerous in the ATXBM hosts than in tumors from CXBM or nonirradiated mice. Dissemination and metastatic growth occurred at a high frequency in the ATXBM hosts (23/29) but not at all in the CXBM hosts (0/32); one pulmonary metastatic nodule was observed in 1/41 nonirradiated tumor bearers. Invasion from the primary subcutaneous site through the peritoneal wall and seeding of the peritoneal cavity occurred in the ATXBM mice but not in the CXBM or nonirradiated tumor bearers. These studies suggest distinct roles for the two immunoglobulin subclasses that localize within the T1699 tumor. It appears that the thymus-independent IgG2b antibody promotes the in situ inflammatory response through an immediate hypersensitivity reaction and that the thymus-dependent IgG2a antibody, which supports antibody-dependent cellular cytotoxic reactions, restrains tumor growth at both the primary and metastatic sites. (29 refs)

79-6518 Immunity to the T1699 Murine Mammary Tumor. I. Thymic Influence and Long-Term Effect of Irradiation on the Humoral Response. (Eng) Parthenais, E. (Transplantation Lab., Univ. Helsinki, Haartmaninkatu 3A, SF 00290 Helsinki 29, Finland); Haskill, S. *J Immunol* 123(3): 1329-1333; 1979.

Immediate hypersensitivity reactions, macrophage-mediated antibody-dependent cellular cytotoxicity (ADCC), and membrane-fluorescent tumor-directed immunoglobulins were assessed in adult-thymectomized, lethally irradiated, bone-marrow-repopulated (ATXBM), syngeneic DBA/2 female mice. ATXBM animals bearing T1699 mammary tumors in the subcutaneous abdominal area displayed normal immediate but not delayed hypersensitivity reactions (DHR) to 3 M potassium chloride T1699 extracts injected into the footpad. Sera from ATXBM tumor bearers passively transferred immediate hypersensitivity but did not support tumor-specific macrophage-mediated ADCC reactions. Macrophage-mediated ADCC antibody synthesis was greatly reduced in the nonthymectomized lethally-irradiated bone-marrow-repopulated (CXBM) animals when compared to nonirradiated tumor bearers. The CXBM mice showed normal T cell function as measured by allograft rejection, antibody response to sheep RBC, and DHR to T1699 antigens. At 14 days after tumor induction, normal levels of IgG2b were found in both ATXBM and CXBM tumor bearer sera by indirect membrane fluorescence. Depressed levels of all other antibody classes tested (IgA, IgM, IgG1, IgG2a, and IgG3) were observed in both the ATXBM and CXBM tumor bearers. These results indicate that IgG2b antibody production in response to T1699 syngeneic tumor antigens is thymus-dependent and suggest that this antibody is the mediator of immediate hypersensitivity. The results also indicate that IgG2a and IgM antibody synthesis is not only thymus-dependent but also sensitive to the long-term effects of irradiation. (16 refs)

- 79-6519 Malignant Transformation of a Warthin Tumor: Case Report, Review of the Literature, and Discussion of Pathology. (Eng) Caldwell, E. H. (Div. Plastic Surgery, Strong Memorial Hosp., 601 Elmwood Ave., Box 661, Rochester, NY 14642); Armiger, W. G.; McDonald, H. M. *Ann Plast Surg* 3(2): 177-181; 1979.

A case history is presented of a 33-yr-old man in whom a benign papillary cystadenoma lymphomatosum (PCL; Warthin's tumor) underwent malignant transformation without previous radiation therapy. The tumor was excised, and histological and electron microscopic studies confirmed that the malignancy originated from the PCL. A review of the literature indicated that several reports of malignant transformation of PCL have been published, but only three have been convincingly proved. These three confirmed cases were all in patients with a previous history of radiation to the neck. In the present case, light microscopy revealed malignant undifferentiated carcinoma in which a single focus of benign PCL was found. Electron microscopy showed malignant epithelial cells of two types: polyhedral or cylindrical cells with dark and light nuclei corresponding to the dark and light cells of the benign PCL; however, the tumor cells had larger nucleoli, a higher nucleus to cytoplasm ratio, and more prominent cytoplasmic rough endoplasmic reticulum and microfilaments. It is believed that this case represents the first report of proved malignant transformation of PCL in a patient with no previous history of radiotherapy. (11 refs)

- 79-6520 Cutaneous Acute Myeloblastic Leukaemia and Squamous Cell Carcinoma. (Eng) Harrison, P. V. (Dept. Dermatology, General Infirmary, Leeds LS2 3EX, England); Rowell, N. R. *Br J Dermatol* 101(2): 207-210; 1979.

The development of a cutaneous deposit of leukemic cells within a squamous cell carcinoma as the first presentation of acute myeloblastic leukemia in a 77-yr-old man is reported. The lesion was excised, ultimate healing was excellent, and the initial response to chemotherapy was excellent, but the patient died from bronchopneumonia. A blood film was characteristic of acute myeloblastic leukemia (85% blast cells), and a bone marrow examination and the postmortem examination confirmed the diagnosis. The fibrinogen level and kaolin cephalin clotting time were reduced, and the prothrombin time, thrombin time, and fibrin degradation products were elevated. Histologic examination of the skin showed a deposit of acute myeloblastic leukemia cells within a poorly differentiated keratinizing squamous cell carcinoma. (23 refs)

- 79-6521 Lymphoepithelioid Cell Malignant Lymphoma (Lennert). (Eng) Bednar, B. (Hlava's 1st Pathological-Anatomical Institute, Faculty Medicine, Charles Univ., Albertov 2039, 128 00 Prague, Czechoslovakia). *Virchows Arch [Pathol Anat]* 382(3): 313-322; 1979.

A prospective study was made of lymphoepithelioid cell malignant lymphoma (LCMM). Typical epithelioid cell formations were found in 175/500 cases of various types of Hodgkin's disease. No distinctive behavior was found in cases with epithelioid structures.

A more detailed study was made of a further series of 23 LCMM's marked by focal nuclear atypicality in their epithelioid cell granulomas. The atypicality destroyed the basic neoplastic structure of the lymph node in many cases, necessitating further biopsy. In this series, not only Hodgkin's disease (7 cases), but also some non-Hodgkin's type malignant lymphomas (3 immunoblastomas, 3 immunocytomas, and 2 T-cell lymphoblastomas) were found. In 6/23 cases, only a tentative diagnosis of LCMM could be made. The epithelioid granulomatous reaction tended to disappear gradually in all cases and was apparently a secondary phenomenon. The cause of the epithelioid cell atypia was not evident, although it proved to be an important diagnostic feature identifying an independent form of LCMM. The subsequent development of this lesion suggested a mildly pleiomorphic, highly malignant lymphoma that might be of B- or T-cell origin. (10 refs)

- 79-6522 Chromosomes and Causation of Human Cancer and Leukemia. XXXII. Unusual Features of Ph⁺-positive Acute Myeloblastic Leukemia (AML), Including a Review of the Literature. (Eng) Abe, S. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263); Sandberg, A. A. *Cancer* 43(6): 2352-2364; 1979.

Five cases of Philadelphia chromosome (Ph⁺)-positive acute myeloblastic leukemia (AML) are described. In all cases, a Ph⁺ chromosome was shown by banding techniques to be due to a translocation between chromosomes 9 and 22. Cases 2 and 4 had more than one Ph⁺, with evidence of only one Ph⁺ translocation accompanying other chromosome abnormalities. Two cases represented an unusual pattern of appearance and disappearance of the Ph⁺-positive clone during their clinical courses. Case 2 was originally Ph⁺-positive (46,XY,Ph⁺), but 2 mo before expiration, the Ph⁺-positive clone was completely replaced by a newly developed Ph⁺-negative clone with an abnormal chromosome 21 (46,XY,21q+). Case 3, primarily Ph⁺-negative, developed a Ph⁺-positive clone among the previously karyotypically normal cells 1 mo before death. The Ph⁺-positive AML cases are discussed in relation to (1) the genesis and significance of the Ph⁺-positive clone, (2) differentiation from the blastic phase of chronic myelocytic leukemia, and (3) general experience with Ph⁺-positive acute nonlymphocytic leukemia (ANLL). Ph⁺-positive cases of ANLL in the world literature are tabulated. (43 refs)

- 79-6523 A Case of Burkitt's Lymphoma. (Pol) Rupniewska, Z. M. (Klinika Hematologii, Instytut Chorob Wewnętrznych AM, ul. Jaczewskiego 8, 20-950 Lublin, Poland); Korobowicz, E.; Metera, M. *Pol Arch Med Wewn* 61(5): 411-414; 1979.

Burkitt's lymphoma was diagnosed in a 21-yr-old man who had never been in an endemic region. The diagnosis was based on the histological examination of a lymph node, which displayed a characteristic starry sky appearance. In the pleural exudate and in the bone marrow, large cells with strongly basophilic cytoplasm and numerous vacuoles (Burkitt's lymphoma cells) were found. The characteristic chromosome markers (14q⁺ and 8q⁺) were absent. The diagnosis was confirmed at autopsy. (7 refs)

79-6524 Burkitt's Lymphoma: Review of the Literature and Report of Four Cases in Denmark. (Dan) Pallesen, G. (Univ. Inst. Pathology, Univ. Aarhus, Kommunehospitalet, DK-8000 Aarhus C, Denmark); Andersen, H.; Jensen, M. K.; Philip, P.; Hansen, N. E.; Badsberg, E.; Vilholm, H. E. *Ugeskr Laeger* 141(27): 1827-1832; 1979.

The histopathology, clinical manifestations, etiology, immunology, and cytogenetics of Burkitt's lymphoma (BL) are reviewed. In addition, the case reports of four BL patients (3 women and 1 man with a mean age of 19.4 yr) are presented. The disease presented as acute leukemia in two patients. In all four patients, the disease was disseminated and predominantly abdominal, corresponding to Stage IV. All the women had bilateral ovarian tumors; one patient had involvement of the jaw and one had sparse involvement of the peripheral lymph nodes. The antibody titer against Epstein-Barr virus (EBV) capsid antigen was slightly but not significantly elevated in the two patients examined. B-lymphocyte markers were demonstrated in both tumors examined and both showed a weak reaction for intracytoplasmic monoclonal immunoglobulin. The tumor cells from three patients were characterized by chromosome abnormalities. In two patients, the marker chromosome 14q+ was demonstrated; in the third, the investigation was inconclusive because of the absence of one chromosome 14 in all mitoses. This feature of the nonendemic type of BL (in which there is no firm association with EBV) is another trait in common with the endemic type of BL (associated with EBV). (59 refs)

79-6525 A Re-examination of the Alleged Monocytic Features of Hairy-Cell Leukaemia. (Eng) Burns, G. F. (Dept. Haematological Medicine, Univ. Cambridge, Cambridge, England); Cawley, J. C. *Scand J Haematol* 22(5): 386-396; 1979.

Several monocytic features of the hairy cells (HC's) of hairy cell leukemia (HCL) were studied in detail. By means of a rosette assay employing erythrocytes (E's) coated with IgG (EAG), a receptor for the Fc of IgG was shown to be strongly expressed on all HC's, whether in suspension or in monolayer. This receptor was shed and reexpressed over a period of approx 6 hr. In EAG rosette formation, the indicator E's were deformed, and the receptor was not blocked by an antiserum to immune-associated-like antigen. Ultrastructural acid phosphatase cytochemistry showed that HC's phagocytose latex particles, but they do not phagocytose a variety of other particles to a significant extent. These features plus data found in the literature are compatible with the current view that HCL is a form of B-cell lymphoproliferation. (47 refs)

79-6526 Ultrastructural and Immunohistological Study of Immunoblastic Sarcoma Developing in Child with Immunoblastic Lymphadenopathy. (Eng) Morris, J. A. (Dept. Pathology, Univ. Leeds, Leeds LS2 9JT, England); Bird, C. C. *Cancer* 44(1): 171-182; 1979.

The ultrastructural and immunohistological features of the first case of immunoblastic lymphadenopathy progressing to immunoblastic sarcoma to occur in a child (a 7-yr-old boy) is reported. The sarcoma cells showed light and electron microscopic features of transformed lymphocytes (immunoblasts), but it was not possible to establish their B-cell origin using a peroxidase-antiperoxidase technique for the demonstration of intracellular immunoglobulins. In the affected lymph nodes there was marked proliferation of reticulum and endothelial cells, both of which contained numerous intranuclear inclusions that may have been of

viral origin. Ultrastructural studies suggest that the amorphous eosinophilic interstitial material, an important diagnostic morphological feature of immunoblastic lymphadenopathy, results from the oblique sectioning of the elongated and branching cytoplasmic processes of reticulum cells. It is postulated that in immunoblastic lymphadenopathy, the proliferation of reticulum and endothelial cells may be the primary event, perhaps stimulated by viral infection, and that the intense lymphocytic and plasmacytic infiltration and sarcomatous transformation occur as secondary phenomena. (26 refs)

79-6527 The Potential Histogenic Relationship of the Peripheral Nerve to Synovioma. (Eng) Ichinose, H. (Dept. Pathology, Tulane Univ. Sch. Medicine, New Orleans, LA 70112); Powell, L.; Hoerner, H. E.; Derbes, V. J.; Byers, J. F. *Cancer Res* 39(10): 4270-4273; 1979.

Three cases illustrating nerve involvement in synoviomas are reported. A 4.4-cm synovial sarcoma of the endothelioid type was found in the deep fascia of the right upper thigh of a 34-yr-old man with an 18-mo history of severe localized tenderness. The tumor contained typical calcospherites and small nonmyelinated nerves, and the peripheral edges showed myxoid deposits adjoining other nerves. A 2.2-cm synovial sarcoma of the epithelioid type was found infiltrating the fascia of the medial aspect of the left os of the second patient, a 70-yr-old woman. The tumor had interstitial areas of myxoid differentiation and small unmyelinated nerves, and a large neighboring nerve showed prominent atypical proliferation of Schwann cells. In the left axilla of the third patient, a 35-yr-old man with an 18-mo history of pain and numbness in the affected area, a synovial sarcoma with calcospherites, multifocal myxoid areas, and cellular epithelioid areas margined by spindle cell fascicles was found. A large nerve of the brachial plexus passed through the tumor, and several other branches were draped across the exterior surface of the tumor. Nonmyelinated nerves within the interior of the tumor seemed to blend with adjoining cancer spindle cells. The data support the hypothesis that synovioma may be neural in origin. (23 refs)

79-6528 Intrathoracic Meningoceles and Neurofibromatosis. (Eng) Erkulvawatr, S. (Dept. Neurology, Medical Coll. Georgia, Augusta, GA 30901); Gammal, T. E.; Hawkins, J.; Green, J. B.; Srinivasan, G. *Arch Neurol* 36(9): 557-559; 1979.

Four cases of intrathoracic meningoceles associated with neurofibromatosis are reported. In all cases, the diagnosis of neurofibromatosis was antecedent to the discovery of the meningocele. All patients were women (19-60 yr old). One patient suffered from severe paraparesis, two from headaches, and the fourth was seen for evaluation of a possible lung carcinoma following the discovery of a soft-tissue mass on a routine chest roentgenogram. These 4 cases bring to 88 the number of thoracic meningoceles, 75 of which have been associated with neurofibromatosis. Several skeletal abnormalities are associated with this lesion, indicating that osseous dysplasias are intrinsic to the disorder. It is conceivable that a combination of regional vertebral and dural dysplasia could lead to the formation of meningocele. (15 refs)

79-6529 Intracranial Meningiomas Related to External Cranial Irradiation. (Eng) Spallone, A. (Istituto di Neurochirurgia, Universita di Roma, Viale dell'Universita 30, 00185 Rome, Italy); Gagliardi, F. M.; Vagnozzi, R. *Surg Neurol* 12(2): 153-159; 1979.

Two cases of multiple meningiomas following irradiation for tinea capitis and one case of meningioma following radiotherapy for a vascular nevus of the scalp are reported. Two patients (a 51-yr-old man and a 25-yr-old man) had been irradiated in infancy and the third (a 44-yr-old woman) at the age of 5. The patients who had been treated for tinea capitis received <800 R, and the third patient received a total of 1,500 R. The latent period was 25-45 yr, which is much shorter than that usually seen in intracranial meningiomas following high-dose irradiation for intracranial tumors (2-10 yr). The difference in latent period suggests that the oncogenic mechanism is different in the two groups and/or dose-related. The previously reported concept of "misregeneration" may explain the causal relationship between low dose irradiation and the development of meningiomas. This theory could account for the long latency period between irradiation and tumor development and might also explain why the tumor is almost always benign. (39 refs)

- 79-6530 Rhabdomyosarcoma Arising in a Pineal Teratoma. (Eng) Preissig, S. H. (Dept. Pathology, Duke Medical Center, Durham, NC 27710); Smith, M. T.; Huntington, H. W. *Cancer* 44(1): 281-284; 1979.

A rhabdomyosarcoma developed in a pineal teratoma in a 14-yr-old boy and was rapidly fatal despite radiation therapy. The teratoma contained anaplastic spindle cells with cross-striations. This is the second reported case of a pineal teratoma giving rise to a rhabdomyosarcoma. (17 refs)

- 79-6531 Sublingual Keratosis and Malignant Transformation. (Eng) Pogrel, M. A. (H. M. Stanley Hosp., St. Asaph, Wales). *J Oral Pathol* 8(3): 176-178; 1979.

The rate of malignant transformation in 19 patients with sublingual keratosis (SK) was studied. Carcinoma subsequently developed in three patients. The SK patients ranged in age from 48-73 yr and included 12 women and 7 men. Among the patients who developed carcinoma there were two men aged 48 and 61 yr and a 65-yr-old woman. The carcinomas developed 4-7 yr after SK. Eight SK patients were heavy smokers, and carcinoma developed in two of them. A fourth SK patient developed carcinoma of the lateral border of the tongue 5 yr later in an area unaffected by leukoplakia. Of the 16 patients who showed no malignant transformation of leukoplakia, 3 remained unchanged, three had repeated biopsies taken, 4 improved, and 6 could not be evaluated on the basis of available information. In a series of 23 patients with carcinomas of the floor of the mouth, the carcinoma arose in a preexisting white lesion in 8 cases. The results suggest that SK has a considerable risk of malignant transformation and that biopsy and meticulous follow-up are mandatory. (5 refs)

- 79-6532 Herpes Simplex Type 2 Encephalitis Concurrent with Known Cerebral Metastases. (Eng) Manz, H. J. (Dept. Pathology, Georgetown Univ. Medical Center, 3900 Reservoir Rd., Washington, DC 20007); Phillips, T. M.; McCullough, D. C. *Acta Neuropathol (Berl)* 47(43): 237-240; 1979.

The case report of a patient with disseminated Herpes simplex encephalitis concurrent with cerebral metastases from a lung carcinoma is presented. The patient, a 62-yr-old woman developed neurologic deficits 7 mo after pulmonary lobectomy for alveolar cell carcinoma of the lung. Computerized tomography scan of the head demonstrated two metastases with marked peritumoral

edema. Dysphasia and right hand paresis improved with therapy, but she developed rhythmic, involuntary movements of the left hand almost 2 mo later. There was progression to multifocal seizures, grand mal seizures, postictal depression, status epilepticus, and coma; the patient died 9 days after the onset of the movement disorder. At autopsy, bronchoalveolar carcinoma was found to be widely disseminated in the lungs and bones, and three metastases were found in the brain. Bland 'ischemic' necrosis in a pseudolaminar pattern was present in the neocortex. Innumerable Cowdry type A intranuclear inclusion bodies were seen in neurons, astrocytes, and oligodendroglia, and Herpes simplex virus type 2 antigen and Herpes-type virions were identified by immunofluorescence and electron microscopy. This case illustrates the potential for the development of neurologic complications due to more than one mechanism in a patient with systemic cancer. (26 refs)

- 79-6533 Giant Cell Tumor in Paget's Disease of Bone: Familial and Geographic Clustering. (Eng) Jacobs, T. P. (Dept. Medicine, Coll. Physicians and Surgeons, Columbia Univ., 630 W. 168th St., New York, NY 10032); Michelsen, J.; Polay, J. S.; D'Adamo, A. C.; Canfield, R. E. *Cancer* 44(2): 742-747; 1979.

Four patients with benign giant cell tumor and one with probable benign giant cell tumor associated with Paget's disease are reported. Three patients were from one family. All patients claimed ancestors who had emigrated from the same small town in southern Italy, and all were born and raised in northern New Jersey. The cases reported here occurred only in bone affected by Paget's disease. The symptoms were caused by encroachment of the tumor upon neighboring structures, and in no instance did distant metastasis of the primary tumor occur. It is suggested that genetic and possibly environmental factors or a combination of both could be responsible for the linkage of these five patients with this highly unusual neoplasm. (25 refs)

- 79-6534 Cell Surface Proteins and Glycoproteins of Metastatic Murine Melanomas and Sarcomas. (Eng) Nicolson, G. L. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA 92717). In: *Biological Markers of Neoplasia: Basic and Applied Aspects*. Proceedings of an international conference held 22-26 May 1978, Leesburg, VA. Ruddon, R. W., ed. (New York; Elsevier): 590 pp.; 227-239; 1978.

The cell-surface proteins and glycoproteins of metastatic murine melanomas and sarcomas selected for blood-borne metastatic colonization of specific organs were studied. There were only slight differences in the surface proteins and concanavalin A-binding components of B16 melanoma lines selected for high and low potential for metastasis to the lung. However, surface proteins of approx 95,000 and 100,00 daltons (95K and 100K) were more "exposed" on B16 lines selected for high potential for metastasis to the brain, than on nonselected parental lines. The incorporation of ¹²⁵I into these two components and the ratio of ¹²⁵I-labeled 100K/95K increased with brain selection. Compared with nonselected lines, ovary-selected variant lines of B16 incorporated more ¹²⁵I into surface proteins of approx 155K and 140K. A variant of MSV3T3 sarcoma selected for lung colonization showed greater exposure of two components of 95K and 140K compared with the parental line, and the parental line showed greater exposure of a protein of approx 250K. Affinity chromatographic analysis of the cell-surface glycoproteins of lung-selected and unselected MSV3T3 variants suggested that the 95K component

was bound and eluted and appeared in greater quantity (or exposure) on the lung-selected line, whereas the 250K component was greater (or more exposed) on the parental line. The possible role(s) of the components identified in these studies in the metastatic process remains to be determined. (31 refs)

- 79-6535 Ultrastructure of Chondroid Syringoma. Role of the Myoepithelial Cell in the Development of the Mixed Tumor of the Skin and Soft Tissues. (Eng) Varela-Duran, J. (Dept. Pathology, Univ. Minnesota Hosps., Box 609 Mayo Memorial Building, 420 Delaware St., S. E., Minneapolis, MN 55455); Diaz-Flores, L.; Varela-Nunez, R. *Cancer* 44(1): 148-156; 1979.

The results of an electron microscopic study of a chondroid syringoma that developed in a 61-yr-old man are presented. The tumor nests were formed by clumps, solid cords, and tubular structures distributed diffusely throughout a stroma of varying density. The tumor was comprised of two different types of cells: dark cells forming the inner layer of the tubuloalveolar and ductal structures and having epithelial features and light cells forming the outer layer of the tubular structures and showing myoepithelial differentiation. The myoepithelial cells seemed to be responsible for the production of the chondroid areas and, thus, the mixed appearance of the tumor. The epithelial cells forming the solid tumor nests showed intracytoplasmic luminal formation and other features that favor the origin of chondroid syringomas from the eccrine sweat gland duct. - 79-6536 Polymorphism of Population of Tumor Cells and Selective Processes. Communication III. Changes in the Ratio of Subpopulations of Ehrlich Ascites Tumor Cells (Strain-ICP) after Exposure to Glucose and Sodium Succinate. (Rus) Fomina, M. M. (Lab. Quantitative Oncology, Inst. Chemical Physics, Moscow, USSR); Minenkova, E. A.; Lankin, V. Z.; Poroshenko, G. G.; Evsejenko, L. S. *Tsitologia* 21(8): 953-958; 1979.

The effect of energy substrates on the polymorphism of a tumor cell population was studied in random-bred albino rats. Animals were given ip transplants of $6-8 \times 10^6$ Ehrlich ascites tumor cells (ICP strain); on days 3-7 after transplantation, mice received ip injections of glucose (100 mg/day) or sodium succinate (10 mg/day). The animals were sacrificed at the end of varying time periods, and the tumor specimens were subjected to cytogenetic analysis. The tumor cell populations from nontreated mice consisted of two subpopulations: one with 44 chromosomes and (A1 + A2 + 2B + C) marker chromosomes, and another with 45 chromosomes and (A + B + 2C) and (A + D + 2C) marker chromosomes. The ip administration of both substrates resulted in a marked shift in the Ehrlich ascites tumor cellularity: there was a marked increase in the frequency of cells carrying 44 chromosomes and the A1 marker (50% on day 5 of transplantation and 100% on day 7) with a corresponding decrease in the frequency of cells with 45 chromosomes and marker A. - 79-6537 Lung Carcinoma Arising in Bronchopulmonary Sequestration. (Eng) Bell-Thomson, J. (Dept. Thoracic and Cardiovascular Surgery, Maimonides Medical Center, 4802 Tenth Ave., Brooklyn, NY 11219); Missier, P.; Sommers, S. C. *Cancer* 44(1): 334-339; 1979.

A squamous cell carcinoma arising in an area of intralobar bronchopulmonary sequestration in the right lower lobe of a 69-yr-old man is reported. The patient had undergone a bilateral nasal polypectomy and also right maxillary antrostomy for chronic sinusitis at age 63, and developed herpes zoster skin lesions at age 67. He was a heavy cigarette smoker until age 63 and drank 1 pint of whiskey daily. He underwent right posterolateral thoracotomy for the carcinoma and has remained well during the 5 yr since surgery. The presence of intrapulmonary sequestration was indicated by a rounded subpleural portion of lung demarcated peripherally by fibroelastic tissue containing bronchi, bronchiolar cysts, fibrous tissue, and unusually large arteriosclerotic arteries. The squamous cell carcinoma was unusual in showing localized and evidently sluggish invasive growth. Only one other case of cancer in an intralobar sequestration has been reported, and in this case the primary lesion may have been elsewhere and the lesion in the sequestration may have been only a metastasis. (13 refs)

- 79-6538 Cell Surface Sialylation of Glycoproteins and Glycosphingolipids in Cultured Metastatic Variant RNA-Virus Transformed Non-producer BALB/c 3T3 Cell Lines. (Eng) Yogeewaran, G. (Dept. Cancer Biology, Salk Inst. Biological Studies, P.O. Box 1809, San Diego, CA 92112); Sebastian, H.; Stein, B. S. *Int J Cancer* 24(2): 193-202; 1979.

The sialic acid composition and the display of cell-surface sialyl components of several metastatic variant RNA virus-transformed nonproducer BALB/c 3T3 cell lines were studied. The compositions of whole cell total, protein-bound, and lipid-bound sialic acid were not appreciably different. The surface sialic acid was positively correlated with the metastatic properties of the lines. The degree of surface sialylation of neuraminidase-treated and untreated cells revealed that 44%-89% of the exposed galactose and/or N-acetylgalactosamine residues of the total cell-surface saccharides were sialylated in highly and intermediately metastatic lines, but only 11%-30% were sialylated in the poorly metastatic and nonmetastatic lines. The cell-surface glycoproteins and glycosphingolipids contributed equally well in their degree of sialylation, and there was a positive correlation between sialylation in vitro and the metastatic properties of the cells in vivo. The cell-surface proteins labeled by lactoperoxidase-catalyzed iodination showed some minor differences between metastatic variant lines. However, glycoproteins detected by the galactose oxidase labeling of neuraminidase-treated and untreated cells showed major differences in composition between the different lines. Four highly metastatic lines were enriched in several sialylglycoproteins, whereas three nontumorigenic lines and two poorly metastatic or nonmetastatic lines contained unsialylated glycoproteins. The results indicate that there is an enhancement of the degree of sialylation of surface glycoconjugates accompanying metastasis in RNA virus-transformed mouse lines. (48 refs)

- 79-6539 Spontaneous Argyrophil Cell Carcinoid in the Glandular Stomach: Immunohistochemical Study of Gastric Endocrine Cells in Normal and Tumour-bearing Mastomys. (Eng) Hakanson, R. (Farmakologiska Institutionen, Solvegatan 10, S-223 62 Lund, Sweden); Alumets, J.; Sundler, F. *Scand J Gastroenterol [Suppl]* 14(53): 27-32; 1979.

The gastric endocrine cells in normal female mastomys and in mastomys bearing spontaneous argyrophil cell carcinoids of the glandular stomach were studied and compared with those of male Wistar rats and male and female NMRI mice. The number of enterochromaffin-like cells and somatostatin cells in the oxyntic mucosa of normal mastomys was much lower than in the rat and

mouse. Although the number of gastrin cells in antral specimens from mastomys was in the same range as that in the mice and rats, the number of enterochromaffin cells was much higher and the number of somatostatin cells much lower. There was no gastrin or somatostatin immunoreactivity in the argyrophil tumor cells of the mastomys, nor was there any 5-hydroxytryptamine fluorescence. Many tumor cells displayed dopamine fluorescence upon L-dopa pretreatment. The only change apparent in the endocrine cells of the gastric mucosa of tumor bearing mastomys was a reduced number of antral gastrin cells. The reduction seemed to increase with tumor size. A reduction in gastrin cell number was also noted in an animal with a transplanted tumor. (19 refs)

- 79-6540 Clinical, Genetic, and Biostatistical Progress in the Cancer Family Syndrome. (Eng) Lynch, H. T. (Dept. Preventive Medicine, Public Health, Creighton Univ. Sch. Medicine, Omaha, NE 68178); Guirgis, H. A.; Harris, R. E.; Lynch, P. M.; Lynch, J. F.; Elston, R. C.; Go, R. C.; Kaplan, E. *Front Gastrointest Res* 4: 142-150; 1979.

The occurrence of cancer and certain biological markers in members of families prone to carcinoma of the colon and endometrium (ie, cancer family syndrome, CFS) was studied. An approx 50% excess lifetime incidence of colorectal/endometrial cancer among the progeny of matings involving an affected direct-line parent suggested that one-half of the affected progeny received a deleterious cancer-predisposing gene from their heterozygous direct-line parents. Segregation analysis for one pedigree (C-196) supported an autosomal dominant inheritance with gene carriers showing a lifetime susceptibility of 89% and a mean onset at 42.5 yr of age. In pedigree C-120, 15 members distributed over three generations had cancer, including six with cancer of the colon, one with cancer of the stomach, one with cancer of the endometrium, and two with cancer of the ovary. The mean age of onset in this family was 44.5 yr (range, 25-67 yr). In pedigree CFS-196, 19 members were tested for a variety of biological markers, and five of the eight markers studied were utilized in deriving an index score for each individual. The 13 unaffected individuals with affected parents had scores ranging from 2 to 29.8. The scores were significant (mean, 16.1, $p < 0.05$) in 4/13 persons and nonsignificant in the remaining 9 (mean 8.3). (28 refs)

- 79-6541 Neoplastic and Nonneoplastic Lesions in Aging (C57BL/6N x C3H/HeN)_F₁ (B6C3F₁) Mice. (Eng) Ward, J. M. (Tumor Pathology Branch, Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Public Health Service, U.S. Dept. Health, Education, and Welfare, Bethesda, MD 20205); Goodman, D. G.; Squire, R. A.; Chu, K. C.; Linhart, M. S. *J Natl Cancer Inst* 63(3): 849-854; 1979.

Neoplastic and nonneoplastic lesions in 2,543 male and 2,522 female untreated (C57BL/6N x C3H/HeN)_F₁ mice used as controls in carcinogenesis tests were tabulated and evaluated. The most common neoplasms in male mice were hepatocellular adenomas and carcinomas, lymphomas, leukemias, and pulmonary adenomas and carcinomas. In female mice, common tumors included lymphomas, leukemias, pulmonary adenomas and carcinomas, hepatocellular adenomas and carcinomas, and pituitary adenomas. The risk of developing most neoplasms increased with the age of the mouse. Hepatocellular carcinomas metastasized in 12% of animals with these tumors. Other than lymphomas and leukemias, few other tumors metastasized. Non-neoplastic lesions included cystic hyperplasia of the uterus, nephritis, ovarian and uterine cysts, inflammatory lesions of the lung, mineralization in the brain, and focal hyperplasias in several

tissues. The presence of focal hyperplasias in lung and pituitary, adrenal, and thyroid glands suggested early stages of neoplasia. (12 refs)

- 79-6542 Demonstration of α_1 -Antitrypsin in Hepatomas. (Eng) Reintoft, I. (Inst. Forensic Medicine, Odense Univ., DK-5000 Odense, Denmark); Hagerstrand, I. *Arch Pathol Lab Med* 103(10): 495-498; 1979.

Sixty-nine primary malignant hepatomas were examined for the presence of α_1 -antitrypsin (α_1 -AT) in tumor cells using immunohistochemical methods. Twenty-eight tumors were α_1 -AT-positive. Diastase-resistant, PAS-positive, and α_1 -AT-positive globules were seen in 11 hepatocellular tumors and 1 cholangiocellular tumor, thus simulating the pattern of α_1 -AT accumulation in hepatocytes in subjects carrying the Z-gene for α_1 -AT. In fact, this pattern was seen in normal liver tissue in eight cases of hepatocellular carcinoma. In ten hepatocellular tumors, the reaction was finely granular throughout the hepatocytic cytoplasm, but was present in only a small number of cells. Still fewer cells were positive in six cholangiocarcinomas. The globular α_1 -AT in tumor cells may be genetically determined when associated with the Z-gene. Reappearance of fetal gene products may have occurred in three hepatocarcinomas that showed globules positive for α -fetoprotein as well as for α_1 -AT. (12 refs)

- 79-6543 Detection of Hepatitis B Surface Antigen in Fixed Tissues of Patients with Cirrhosis and Hepatoma. (Eng) Theodoropoulos, G. (2 Dryadon St., Chalandri-Attikis, Greece); Nakopoulou, L.; Repanti, M.; Papacharalampous, N.; Melissinos, K. *Virchows Arch [Pathol Anat]* 382(3): 293-300; 1979.

Light microscopy was used to detect hepatitis B surface antigen (HBsAg) in liver specimens from 79 patients with cirrhosis and 99 with hepatoma. The study was carried out on fixed material using orcein staining, immunoperoxidase staining, and indirect immunofluorescence (IIF). HBsAg was detected by radioimmunoassay in the serum of 38 patients with cirrhosis and 36 with hepatoma. HBsAg-positive cells were observed in 31 of the former by orcein staining and in 32 by the immunoperoxidase and IIF methods. Among the 36 seropositive hepatoma patients, HBsAg was detected in the surrounding nonneoplastic part of the liver, cirrhotic or not, in 30 by orcein staining and in 34 by the immunoperoxidase and IIF methods. Positive solitary tumor cells were seen occasionally in 16/36 patients using orcein, in 9/36 using peroxidase, and in 7/36 by IIF. The results do not support the hypothesis of a direct oncogenic effect of HBsAg on liver cells, since this antigen was detected mainly in the nonneoplastic part of the liver tissue and only occasionally in the tumor cells. Of the 63 seronegative hepatoma patients, 3 showed some round, orcein-positive inclusion bodies in the cytoplasm of neoplastic and non-neoplastic cells; these bodies were not stained by the two immunological methods. (23 refs)

- 79-6544 Spontaneous Tumors and Common Diseases in Three Types of Hamsters. (Eng) Pour, P. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42d St. and Dewey Ave., Omaha, NE 68105); Althoff, J.; Salmasi, S. Z.; Stepan, K. *J Natl Cancer Inst* 63(3): 797-811; 1979.

Three types of hamsters designated as inbred cream (Epp/e/e), linebred white (EPP/c^dc^d/RB/A), and linebred albino (EPP/c^dc^de/e) were examined histopathologically for spontaneous

disease. All hamsters were maintained simultaneously for life under identical standard laboratory conditions. Survival time in cream hamsters (CH) was shorter than that in white hamsters (WH) and that in albino hamsters (AH). More tumors and malignant lesions unrelated to survival were found in AH compared with CH and WH; in addition, the multiplicity of neoplasms was more pronounced in AH. The predominating tumor types differed in each line: Pancreatic islet cell neoplasms were most common in CH; adrenal gland tumors predominated in WH; and thyroid gland tumors were more frequent in AH. The relative incidence of spontaneous tumors varied among the lines. Some tumors seemed strain-specific and were not seen in other lines; eg, malignant melanomas occurred only in CH and WH. Certain neoplasms, eg, those of the thyroid and adrenal gland were found more often in one sex than the other. The three hamster groups differed also in nonneoplastic disease. Detailed histopathologic findings are presented and compared with data on the Syrian golden hamster, the ancestral line of these three groups. (28 refs)

- 79-6545 **Metanephrogenic Epithelial Hamartomas. A Contribution to their Morphology, Evolution, and Significance.** (Ger) Stambolis, C. (Institut Pathologie, Universitätsklinikum der Gesamthochschule Essen, Hufelandstrasse 55, D-4300 Essen, W. Germany). *Zentralbl Allg Pathol* 123(1/2): 62-70; 1979.

Neoplastic metanephrogenic lesions without mitoses or signs of malignancy were found in the intact renal parenchyma of three patients (1 boy, 2 girls, aged 3.5, 4, and 5 yr, respectively) with Wilms' tumor. These lesions represented regressive forms of the nodular renal blastema-nephroblastomatosis complex. They were characterized as simple or diffuse metanephrogenic epithelial hamartomas. Small lesions showed involution resulting in scars. In the central parts of larger lesions, cysts and adenomas were detected. The adenomas were multicentric and revealed compact-epithelial, papillary-psammomatous, cystic-multilocular, and tubulopapillary forms. All lesions were subcapsular and occasionally occurred in the zone of the columnae renales. There appears to be a close relationship between the metanephrogenic epithelial hamartomas and the nodular renal blastema-nephroblastomatosis complex; they can occur in the same kidney, and often also bilaterally. They are most frequent in patients with Wilms' tumors. (26 refs)

- 79-6546 **On the Nature and Significance of Nodular Renal Blastema.** (Ger) Stambolis, C. (Institut Pathologie, Universitätsklinikum der Gesamthochschule Essen, Hufelandstrasse 55, D-4300 Essen, W. Germany). *Zentralbl Allg Pathol* 123(1/2): 3-8; 1979.

Neoplastic lesions found in intact renal parenchyma of 24 children with Wilms' tumors (12 boys, 12 girls; average 31 mo) are presented. The patients included two brothers, aged 3 and 4 yr, and a girl with aniridia. Nodular renal blastema and multiple small Wilms' tumors were found in one patient, a 6-mo-old boy with hemiatrophy. Metanephrogenic hamartomas were found in three other patients. Nodular renal blastema, small Wilms' tumors, and metanephrogenic hamartomas occur alone, are mostly bilateral, and usually occur in younger children. In older children, these neoplastic lesions are almost always associated with Wilms' tumor. They are related to certain congenital anomalies. The findings suggest that there is a genetic relationship between the nodular renal blastema-nephroblastomatosis complex and Wilms' tumor. (31 refs)

- 79-6547 **Deficiency of Dopamine- β -hydroxylase. A New Mechanism for Normotensive Pheochromocytomas.** (Eng) Feldman, J. M. (Duke Univ. Medical Center, Box 2963, Durham, NC 27710); Blalock, J. A.; Zern, R. T.; Shelburne, J. D.; Gaede, J. T.; Farrell, R. E.; Wells, S. A. *Am J Clin Pathol* 72(2): 175-185; 1979.

The case of a 28-yr-old normotensive man with bilateral pheochromocytomas (PCCs) is compared with those of four hypertensive patients with PCCs. The tumors of the normotensive patient contained large amounts of dopamine (DA), small quantities of norepinephrine (NE), and no epinephrine (E). The PCCs of the hypertensive patients contained large amounts of DA, NE, and, in some tumors, E. The small amount of NE in the tumors of the normotensive patient was due to a dopamine- β -hydroxylase deficiency in the tumors. The small amount of E was due to a deficiency in phenylethanolamine-N-methyltransferase (PNM), as well as to deficiency in the PNM substrate, NE. Many of the electron-dense secretory granules in the predominantly DA-containing PCCs of the normotensive patient were morphologically similar to granules of NE. However, these granules tended to be slightly smaller and more variable in size and shape than the NE-containing granules of one hypertensive patient. The large amount of homovanillic acid (HVA) in the preoperative, but not the postoperative, urine of the normotensive patient suggested that the tumors secreted DA, whereas the normal excretion of HVA by the hypertensive patients suggested that their tumors did not secrete DA. The absence of hypertension in a patient with PCC might be due to a deficiency in tumor dopamine- β -hydroxylase activity, with a resulting increase in DA secretion and decrease in NE secretion. (40 refs)

- 79-6548 **The Prognostic Value of Axillary Lymph Gland Sinus Histiocytosis in Female Mammary Carcinoma.** (Eng) Yu, H. (Dept. Pathology, Cancer Inst., Chinese Acad. Medical Sciences, Republic of China). *Chin Med J* 92(5): 353-359; 1979.

The relationship between the axillary lymph node sinus histiocytosis (SH) reaction and the prognosis of breast cancer was studied using 228 breast biopsy specimens from untreated female breast cancer patients and 7,586 lymph nodes. The 5- and 10-yr survival rates among the 228 patients were 58.8% and 46.9%, respectively. The SH reaction was mild (SH+) in 35 cases, moderate (SH++) in 92 cases, and marked (SH+++) in 101 cases. The 5-yr survival rate was 22.9%, 45.7%, and 83.2% among those with SH+, SH++, and SH+++ reactions, respectively ($p < 0.002$). Prognosis was influenced by the presence and extent of lymph node metastasis, but the good prognosis associated with increased SH reaction was demonstrated even in patients with lymph node metastases. The relationship between intensity of the SH reaction and survival rate was most obvious in clinical Stages II and III and in pathologic typing groups II₁, II₂, and III. This indicates the importance of the body's reticuloendothelial system immunity reaction in fighting tumors. (7 refs)

- 79-6549 **Paracortical Activity in the Lymph Nodes Draining Female Breast Carcinoma.** (Eng) Syrjanen, K. J. (Dept. Pathology, Jorvi Hosp., 02740 Espoo 74, Finland). *Neoplasma* 26(1): 95-102; 1979.

A series of 302 consecutive breast carcinomas seen at a Finnish hospital between 1960 and 1976 were assessed histologically, with special attention being focused on the nuclear grade of the tumor, the stromal lymphocyte reaction, and the morphology of the paracortical areas of the regional lymph nodes. These morphologic

parameters were correlated with the 5-yr survival data of the patients. The nuclear grade of the primary tumor was directly related to 5-yr survival, as was the paracortical activity of the regional lymph nodes. The paracortical activity was inversely related to the frequency of nodal metastases, which were a sign of poor prognosis. The morphology of the regional lymph node paracortex is valuable in evaluating host resistance criteria in association with breast carcinoma. (19 refs)

- 79-6550 Malignancies Associated with Hemorrhagic Gastritis. (Eng) Chait, M. M. (Dept. Medicine, Gastroenterology Service, Memorial Sloan-Kettering Cancer Center, New York, NY 10021); Winawer, S. J. *Am J Proctol Gastroenterol Colon Rect Surg* 30(4): 14-16; 1979.

The possibility of an association between specific malignant states and hemorrhagic gastritis was evaluated in 82 cancer patients with hemorrhagic gastritis diagnosed during a 5-yr period. Fifty-six patients were under severe physiological stress; 26 were without such stress but were receiving exogenous gastric irritants (salicylates, alcohol, indomethacin, corticosteroids). The greatest proportion (18/56) of patients in the stressed group had a hematologic malignancy; in the general hospital population during the study period, this accounted for only 9% of all cancers. In the nonstressed group, the most common malignancy was breast cancer (11/26), but its distribution was similar in the nonstressed patients and in the general cancer population (22%). Twenty-five nonstressed patients were receiving salicylates. A malignancy occurred in the stomach of four stressed patients and two nonstressed patients. A history of peptic ulcer disease was documented in eight stressed and seven nonstressed patients. Chemotherapeutic agents such as 5-fluorouracil, cyclophosphamide, and bleomycin were administered to 12 stressed patients and 4 nonstressed patients. These findings indicate that patients with hematologic malignancies are susceptible to stress ulcer bleeding and that chemotherapeutic agents, corticosteroids, and a history of peptic ulcer disease may be potentiating factors in the development of hemorrhagic gastritis in cancer patients. (17 refs)

- 79-6551 Menopausal Genital Tract Hemorrhages. A Report of 143 Cases. (Fre) Lieveaux, A. (Service de Gynecologie, Hopital Lariboisiere, 2 rue Ambroise-Pare, 75010 Paris, France). *Gynecologie* 30(3): 211-215; 1979.

The causes of genital tract hemorrhage were analyzed in 143 menopausal women. Cancer was identified as the cause of the hemorrhage in 12/143 women: there were 9 endometrial adenocarcinomas, including 1 intraepithelial adenocarcinoma; 2 epitheliomas of the uterine cervix; and 1 epithelioma of the Fallopian tube. Eleven of the patients were 57-67 yr old, and the twelfth was 81 yr old. Endocervical polyps were found in 12/143 women, benign endometrial polyps in 5, fibrous intracavitary polyps in 4, and estrogen-secreting tumors in 2. The findings indicate that, contrary to an earlier belief, cancer is a rather rare cause of genital tract hemorrhage in menopausal women. (20 refs)

- 79-6552 Endometrial Carcinoma in Previously Ovariectomized Patients. (Eng) Gal, D. (Dept. Obstetrics and Gynecology, Brookdale Hosp. Medical Center, Brooklyn, NY 11212); Neuhoff, S.; Tancer, M. L. *Gynecol Oncol* 8(1): 44-48; 1979.

Three cases of endometrial adenocarcinoma (EAC) occurring in women who had previously undergone bilateral oophorectomy (BO) and who had not used postmenopausal estrogens are reported. A 63-yr-old nulligravida who had undergone BO for ovarian cysts at age 33 was diagnosed as having EAC Stage IA, Grade I. A 73-yr-old nulligravida who had undergone BO 40 yr previously was diagnosed as having well-differentiated EAC Stage IB, Grade I. A 72-yr-old nulligravida who had undergone BO 37 yr previously was diagnosed as having well-differentiated EAC Stage IA, Grade I. The adenocarcinoma had invaded the myometrium to a depth of one-third its thickness. Endocrine studies indicated low preoperative levels of endogenous androgens without significant postoperative (hysterectomy) variation. Luteinizing hormone and follicle-stimulating hormone levels decreased after hysterectomy. These results are consistent with the possibility of a relationship between the uterus and pituitary activity in patients with endometrial cancer. (30 refs)

- 79-6553 Early (Stage A) Prostatic Cancer. IV. Methodological Criteria for Histopathological Diagnosis. (Eng) Battaglia, S. (Istituto di Anatomia e Istologia Patologica, Università di Modena, Via Berengario 4, I-41100 Modena, Italy); Barbolini, G.; Botticelli, A. R. *Virchows Arch [Pathol Anat]* 382(3): 245-259; 1979.

The incidence, morphology, and etiology of Stage A prostatic cancer or prostatic microcarcinoma (PMC) were studied. The prostates of 100 patients treated by subtotal prostatectomy for benign prostatic hyperplasia (BPH) were analyzed by routine and step-section techniques. The incidence of PMC was 41% by the former and 86% by the latter technique. Assessment of the size of PMC, as measured by the sum of the two main diameters, resulted in three PMC groups: A₁, A₂, A₃. The last of these may represent a frankly malignant condition, judged by size and histological appearance. The number of multicentric foci increased from A₁ to A₃. Histologically, A₁ and A₂ consisted of clear-celled tubular adenocarcinomas, but A₃ showed a variable histological pattern (7 clear-celled tubular adenocarcinomas, 4 cribriform adenocarcinomas, and 1 dark-celled tubular adenocarcinoma). A₁ decreased and A₂ and A₃ increased with age. (132 refs)

EPIDEMIOLOGY AND BIOMETRY

- 79-6554 Tumors of the Eye and Adnexa in the Sudan. (Eng) Malik, M. O. (Pathology Dept., Faculty of Medicine, P.O. Box 2925, Riyadh, Saudi Arabia); El Sheikh, E. H. *Cancer* 44(1): 293-303; 1979.

The frequency, sex and age distribution, site, pathologic types, and geographic and racial distribution of 854 tumors of the eye and adnexa in Sudanese patients were analyzed. Of 279 primary malignant tumors (frequency ratio 4.3%), conjunctival squamous carcinoma was the commonest (50.4%), followed by retinoblastoma (20.8%) basal cell carcinoma (6.1%), and malignant melanoma (4.6%). Conjunctival carcinoma and allied epithelial lesions occurred much more often in Northern than in Southern Sudan, and no basal cell carcinoma of the eyelids was recorded in the latter. Retinoblastoma and melanoma showed certain tribal predilections. Most cases of Burkitt's lymphoma occurred in Southern Sudan. It is concluded that geographic and racial factors play important roles in determining the frequency and pattern of eye neoplasms in the Sudan. (60 refs)

- 79-6555 Lipoma of the Cauda Equina (Lumbosacral Lipoma): A Study of 74 Cases Operated in Childhood. (Eng) Rickwood, A. M. (Children's Hosp., Sheffield S10 2TH, England); Hemalatha, V.; Zachary, R. B. *Z Kinderchir Grenz* 27(2): 159-169; 1979.

In a series of 74 cases of lipoma of the cauda equina operated in childhood, females outnumbered males by 2 to 1, and associated congenital anomalies were uncommon. Obvious paralysis was rarely present at birth, but it became progressively more common with age. In most patients, the neurological status remained unchanged postoperatively. Long-term follow-up revealed that there was a high incidence of neurogenic bladder dysfunction and lower limb paralysis in these patients. Early operative intervention reduced the more severe degrees of leg paralysis, but had relatively little impact on the incidence of minor leg paralysis and neurogenic bladder. (15 refs)

- 79-6556 Racial Differences in Melanoma Incidence. (Eng) Crombie, I. K. (Birmingham Regional Cancer Registry, Queen Elizabeth Hosp., Birmingham, England). *Br J Cancer* 40(2): 185-193; 1979.

The incidences of malignant melanoma recorded by 59 population-based cancer registries distributed throughout the world were investigated to determine the effects on these incidences of race and skin color. White populations exhibited a wide range of melanoma incidence, and women commonly, although not invariably, had a higher incidence than men. Nonwhite populations experienced in general a much lower incidence of melanoma, although there was some overlap of white and nonwhite rates. No predominant sex difference emerged among nonwhites. Populations of African descent had a higher incidence than those of Asiatic origin, but it was concluded that this was due largely to the high frequency of tumors among Africans on the sole of the foot. A clear negative correlation between degree of skin pigmentation and melanoma incidence emerged for the exposed body sites. These data provide strong support for the hypotheses that UV radiation is a major cause of malignant melanoma and that melanin pigmentation pro-

tections against it. Further research is required to elucidate the etiology of melanoma of the sole of the foot. (31 refs)

- 79-6557 Cancer Mortality in 1970-1972 Among Polish-Born Migrants to England and Wales. (Eng) Adelstein, A. M. (Office Population Censuses and Surveys, Medical Statistics Div., St. Catherine's House, 10 Kingsway, London WC2B 6JP, England); Staszewski, J.; Muir, C. S. *Br J Cancer* 40(3): 464-475; 1979.

The cancer mortality of Polish migrants to England and Wales during 1970-1972 was compared with that prevailing in England and Wales and that prevailing in Poland; these data were compared with previously published data for Polish-born migrants in the US and in Australia. Compared with mortality rates in both their country of birth and immigration, Polish migrants had intermediate values for cancers of the stomach, intestinal tract, and lung. For age-groups >74 yr, lung cancer mortality among the migrants was higher than that in Poland or that in England and Wales. Polish migrants had a higher mortality from lymphomas in both sexes and from leukemia and esophageal cancer in men than in Poland or in England and Wales. Female breast cancer mortality among Polish migrants was much higher than in Poland, approaching the high mortality rates prevailing in England and Wales. A similar trend was observed for prostate cancer, but comparisons were based on smaller numbers and on less reliable data. Follow-up of these migrants might help elucidate the relative roles of environment and length of residence in differences in cancer risk among these populations. (9 refs)

- 79-6558 Cancers of the Large Bowel. Associated Disorders in Individuals. (Eng) Adelstein, P. (Unit Clinical Epidemiology, Oxford Regional Health Authority, Old Road, Headington, Oxford, England); Baldwin, J. A.; Fedrich, J. *Cancer* 43(6): 2553-2557; 1979.

Data collected in the 1963-1967 Oxford Record Linkage Study were analyzed to ascertain any previously unsuspected associations between cancer of the large bowel and other diseases in individuals and to quantify the relative risks of disorders already known to be associated. In men, significant associations were shown between cancer of the large bowel and cancer of the prostate. In women, cancer of the colon was associated with breast cancer, and cancer of the rectum was associated with a mixed group of genital cancers. The relative risk of colorectal cancer associated with previous benign neoplasms of the large bowel and with ulcerative colitis was 20 and 25, respectively. There was no significant association with appendicitis or longstanding diverticular disease. (8 refs)

- 79-6559 Dietary Fibre and Regional Large-Bowel Cancer Mortality in Britain. (Eng) Bingham, S. (Dunn Clinical Nutrition Centre, Addenbrooke's Hosp., Cambridge, England); Williams, D. R.; Cole, T. J.; James, W. P. *Br J Cancer* 40(3): 456-463; 1979.

The relationship between food intake and large bowel cancer was assessed by calculating the av intakes of foods, nutrients, and

dietary fiber in the different regions of Great Britain and relating these to the regional pattern of death from colon and rectal cancers between 1969 and 1973. No significant associations were found with the consumption of fat, animal protein, or beer, nor with current estimates of total dietary fiber intake. Av intakes of the pentose fraction of total dietary fiber, as well as of vegetables other than potatoes, were negatively correlated with the truncated age- and sex-standardized death rates from colon cancer ($r = -0.960$ and -0.940). Specific components of dietary fiber may therefore inhibit colon carcinogenesis. (28 refs)

- 79-6560 Alcohol and Oesophageal Cancer: An Assessment of the Evidence from Routinely Collected Data.** (Eng) Chilvers, C. (Epidemiological Monitoring Unit, London Sch. Hygiene and Tropical Medicine, London, England); Fraser, P.; Beral, V. *J Epidemiol Commun Health* 33(2): 127-133; 1979.

Mortality and morbidity due to esophageal cancer in England and Wales were investigated. The mortality rate declined after 1911, then increased during the 1950's in all except the oldest age groups. The generation of males born in 1906 had a lower mortality than any preceding or succeeding generation. Morbidity rates increased 52% among males and 54% among females during the period 1962-63 to 1973-74. Since 1900, there was a steady decline in the consumption of alcohol until after World War II, when consumption increased. Consumption of beer contributed to total alcohol consumption. For both males and females, cohort mortality was closely correlated with the per capita consumption of total alcohol when the cohort was aged 25-29 yr ($p < 0.01$). Cigarette smoking has increased steadily since 1905 except for a sharp decline between 1946 and 1950. There was no relationship between cigarette consumption in different generations and mortality from esophageal cancer. Mortality from cirrhosis of the liver and esophageal cancer was highly correlated on a regional basis among males ($p < 0.1$) but not among females. Internationally, for males, but not females, there was also an association between total alcohol consumption and esophageal cancer ($p < 0.01$); there was a weaker association with wine ($p < 0.05$) but not beer or spirit consumption. The international data suggest that ethyl alcohol itself rather than any specific alcoholic beverage is associated with esophageal cancer. (29 refs)

- 79-6561 The Incidence of Gastric Cancer and High-Risk Groups.** (Pol) Rybicka, J. (Klinika Gastroenterologii, Instytut Chorob Wewnętrznych Śląskiej Akademii Medycznej, ul. Medyków, 40-752 Katowice, Poland); Gibinski, K.; Nowak, A.; Czarnecka, K. *Pol Arch Med Wewn* 61(5): 403-410; 1979.

A prospective study was made of 4,538 patients who had undergone diagnostic endoscopy of the upper digestive tract. Three gastric cancer risk groups were identified: Group A (181 patients who underwent partial gastric resection), Group B (754 patients with a family history of cancer), and Group C (155 patients with anacidity). The overall gastric cancer incidence was 194/4,538; the group incidence was 12/181 in Group A, 31/754 in Group B, 14/155 in Group C, and 137/3,448 in the remaining patients. The incidence of endoscopic changes (inflammation, erosion, ulcers, and deformation of the pylorus and duodenal bulb; inflammation, erosion, ulcers and polyps of the stomach) did not differ substantially between the three high-risk groups. The mean age of the tumor-free patients was 48.3 yr in Group A, 47 yr in Group B, and 47.4 yr in Group C. The mean age of the gastric cancer patients was: 58.6 yr in Group A, 57.8 yr in Group B, and 67.2 yr in Group C. In Group A, the postresection incidence of gastric cancer was 4/90 after 5-9 yr, 0/50 after 10-14 yr, 1/19 after

15-19 yr, 2/12 after 20-24 yr, 2/5 after 25-29 yr, and 3/5 after 30-34 yr. The findings indicate that patients with past gastric resection, a family history of cancer, and anacidity should be subjected to endoscopic examinations at regular intervals to increase the detection of early gastric cancer. (19 refs)

- 79-6562 Ewing's Sarcoma: An Approach to Radiological Diagnosis.** (Eng) Lombardi, F. (Istituto Nazionale Tumori, Via G. Venezian, 1, 20133 Milan, Italy); Gasparini, M.; Gianni, C.; Petrillo, R.; Tesoro-Tess, J. D.; Volterrani, F.; Musumeci, R. *Tumori* 65(3): 389-399; 1979.

The radiographs of 83 patients with histologically confirmed Ewing's sarcoma were studied. Of the 49 male and 34 female patients, 59% were less than 15 yr of age. Pain was present in 79% and local swelling in 55%, and in two children, the pain was associated with paraplegia. The av time from onset of symptoms to diagnosis was 20 wk. The most common site of involvement was the long (54%) and flat (35%) bones; the small bones were involved in 8%, and the onset was extraosseous in 3%. The diaphysis alone was the site of disease in 41% of the patients, the metaphysis alone in 5%, and both regions were simultaneously involved in 54%. The radiographic findings were always clearly positive. The incidence of chest metastases was 24%, and bone metastases were found in 17/78 patients (22%). The incidence of lymph node metastases in 40 patients without widespread disease was 13%. Two patients had metastatic soft tissue masses. Fifty-seven patients were considered to have localized and 26 widespread disease. In the patients with initially localized disease, metastases later appeared in 28/57 (49%). (20 refs)

- 79-6563 Oesophageal Lesions in Northern Iran: A Premalignant Condition?** (Eng) Crespi, M. (Regina Elena Inst., Rome, Italy); Grassi, A.; Amiri, G.; Munoz, N.; Aramesh, B.; Mojtabai, A.; Casale, V. *Lancet* 2(8136): 217-220; 1979.

To identify possible precancerous lesions of the esophagus, 218 men and 212 women (15-70 yr old) in northern Iran were examined endoscopically. Of the 430 subjects, 43% were of low and 43% were of medium socioeconomic status. Unspecific gastrointestinal symptoms of long duration were present in 39%, the dental condition was poor in 69%, esophagitis was found in 86%, and esophageal varices were observed in 14%. Esophageal cancer was diagnosed endoscopically in seven patients. Biopsies of 418 patients showed chronic esophagitis in 80%, and acanthosis accompanied by slight hyperkeratosis and parakeratosis was present in a few. Invasive carcinoma was detected in 11 subjects. In general, there was good correlation between the endoscopic and histological findings. Esophagitis involved the middle and lower thirds of the esophagus (the common sites for esophageal cancer) in 90% of affected patients. A family history of esophageal cancer was found in 28% of the subjects with normal esophaguses, 30% of those with esophagitis, and 4/11 patients with cancer. The very high prevalence of chronic esophagitis in northern Iran, where a high incidence of esophageal cancer has also been reported, suggests that these two lesions are associated. (18 refs)

- 79-6564 Correlation Between Cancer Mortality and Alcoholic Beverage in Japan.** (Eng) Kono, S. (Dept. Public Health, Faculty Medicine, Kyushu Univ., Fukuoka 812, Japan); Ikeda, M. *Br J Cancer* 40(3): 449-455; 1979.

Geographical correlations between standardized cancer mortality ratios (SMRs) and consumption of different types of alcoholic

beverages (sake, synthetic sake, shochu, beer, wine, and whiskey), cigarette smoking, and urbanization were examined for all 46 prefectures in Japan. Suggestive correlations were observed between esophageal cancer in males and both shochu and whiskey drinking ($r = 0.27$ and 0.22 respectively), between rectal cancer in males and wine consumption ($r = 0.45$), and between cancer of the prostate and shochu drinking ($r = 0.50$). These correlations were also confirmed by the partial correlations between cancer SMRs and consumption of alcoholic beverages in general when urbanization and cigarette smoking variables were controlled. Although cancer of other sites also correlated with certain types of alcoholic beverages, these associations seemed to be secondary to other factors. The validity of higher-order partial correlations and the problems of correlation study are discussed. (23 refs)

- 79-6565 Role of Diet, Alcohol and Tobacco in Oesophageal Cancer, as Illustrated by Two Contrasting High-Incidence Areas in the North of Iran and West of France. (Eng) Tuyns, A. J. (International Agency Res. Cancer, 150 Cours Albert Thomas, F-69372 Lyon Cedex 2, France); Pequignot, G.; Jensen, D. M. *Front Gastrointest Res* 4: 101-110; 1979.

The role of diet, alcohol, and tobacco in the etiology of esophageal cancer (EC) was studied based on data from high-incidence areas in northern Iran and western France. In northern Iran, overall diet in the high-incidence regions was poorer than in other regions, and the consumption of tea by males was much greater. Opium use was also widespread in the high-incidence areas. In western France, pyridoxine and daily alcohol intake by EC patients was approx two-fold greater than by controls, and the total caloric intake by the EC patients was higher. The EC patients ate less meat; more offals; more salted butter; less fatty foods other than butter and oil; more vegetables, potatoes, and smoked fish; and less chocolate than the controls. There were fewer consumers of mineral water and more consumers of beer, cider, wine, and cider distillates among the EC cases than among the controls. The data do not indicate the existence of one common carcinogen present in the diet which might be considered the sole agent of EC. (26 refs)

- 79-6566 Carcinoma of the Oesophagus in Indian Jews in Beersheba, Israel. (Eng) Odes, H. S. (Gastroenterology Unit, Soroka Univ. Hosp., Beersheba, Israel); Krawiec, J. *Front Gastrointest Res* 4: 96-100; 1979.

The incidence of esophageal carcinoma (EC) in Beersheba, Israel during the period 1961-1977 was studied. Of the 21 cases of EC recorded, 9 were among Jews of Indian origin and 12 were among Iraqi, Moroccan, Iranian, and Ethiopian Jews (Sephardi Jews) and European Jews (Ashkenazi Jews). The Indian group included 3 men and 6 women, all of whom presented with dysphagia of less than 3 mo duration and tumors in the middle or lower third of the esophagus. Eight patients had squamous carcinomas, and one had an anaplastic tumor. The non-Indian group included eight men and four women. The middle esophagus was involved most often among the Ashkenazi Jews, and the lower esophagus was the usual site in the Sephardi group. Squamous tumors were present in 10 patients, and 1 patient had an anaplastic carcinoma in the upper esophagus. All patients had dysphagia of recent onset. Indian Jews presented at a mean age of 53.5 yr and non-Indian Jews at 65.5 yr ($p < 0.01$); there were not significant age differences among Ashkenazi and Sephardi Jews. The Indian and non-Indian patients did not differ significantly with respect to average period of residence in southern Israel. (8 refs)

- 79-6567 Some Epidemiological Aspects of Postmenopausal Bleeding and Endometrial Carcinoma in Israeli Women of Different Ethnic Groups. (Eng) Schachter, A. (Dept. Obstetrics and Gynecology, Beilinson Medical Center, Tel Aviv Univ. Medical Sch., Tel Aviv, Israel); Segal, A.; Bahary, C.; Joel-Cohen, S. J. *Cancer Cytol* 19(1): 13-20; 1979.

Epidemiologic aspects of postmenopausal bleeding (PMB) and endometrial carcinoma (EC) were studied in 856 Israel residents with PMB (537 Western origin, 208 Eastern, 111 Israeli), 123 with EC (82 Western, 21 Eastern, 20 Israeli), and 996 controls. The av ages were 56 yr and 58.4 yr for the PMB and EC patients, respectively. Menarche began before the age of 13 yr in 83.5% of the EC patients, 66.4% of the PMB patients, and 48.2% of the controls. The av ages at menopause were 48.6, 51.8, and 49.5 yr for the PMB, EC, and controls, respectively. Of the PMB patients, 3.2% were single, compared with 4.1% of the EC group. Thirteen percent of the EC patients were childless, compared with 6.3% of the controls. The av length of sexual life was 34.3 yr for the EC women, 31.4 yr for the PMB women, and 29.5 yr for the controls. An additional primary malignancy was noted in 18.7% of EC cases, 6.1% of PMB cases, and 6.6% of controls. The EC and PMB patients did not differ significantly with respect to previous estrogen therapy. Diabetes was observed in 9.8% of EC patients, 6.3% of PMB patients, and 3.8% of controls. The incidence of obesity was 33.8% in the EC group compared with 17.3% in the control group. The incidence of hypertension in EC patients (36.6%) was double that of the controls, and estrogenic activity in these women was greater than expected for women of their age. Fibroids were present in 15.4% of the EC patients, 8.2% of the PMB patients, and 6.68% of the controls. (31 refs)

- 79-6568 Risk Factors in Endometrial Carcinoma with Special Reference to the Use of Estrogens. (Eng) Salmi, T. (Dept. Obstetrics and Gynecology, Univ. Turku, Turku, Finland). *Acta Obstet Gynecol Scand [Suppl]* 86: 119 pp.; 1979.

A literature review concerning endometrial cancer epidemiology and estrogen use as a risk factor in endometrial carcinoma is presented together with an original case-control study. The study included personal interviews and was conducted to determine the possible risk factors of endometrial carcinoma with emphasis on the role of exogenous hormones. The cases were 318 endometrial carcinoma patients treated during 1970-1976 in Finland. Controls were matched for age within 5 yr, wt, and social class to form 282 matched pairs. The mean wt of the endometrial carcinoma patients was 73.3 kg, and that of the controls was 66.4 kg. Of the 318 patients, 26.1% were considered obese, compared with 11.8% of the controls. Analysis of the use of continuous medication (hormones excluded) indicated that the relative risk of endometrial carcinoma was 2.4 among those using medication for diabetes mellitus and 1.9 among those using digitalis. Controls had used hormones for some gynecological indication significantly ($p < 0.05$) more often than did the patients, but patients had received hormones because of menstrual disorders significantly more often than did controls. The duration and scheme of estrogen treatment did not differ between patients and controls. It is concluded that obesity may be the main risk factor in endometrial carcinoma. A long-standing endogenous hormonal imbalance manifesting itself as a menstrual disorder and leading to hormone therapy may increase endometrial carcinoma risk. The use of exogenous estrogens does not produce an excess risk of endometrial carcinoma in Finland. (218 refs)

- 79-6569 Numbers of Asbestos Bodies in Urban Patients with Lung Cancer and Gastrointestinal Cancer and in Mat-

ched Controls. (Eng) Churg, A. M. (Dept. Pathology, HSW595, Univ. California Sch. Medicine, San Francisco, CA 94143); War-nock, M. L. *Chest* 76(2): 143-149; 1979.

The numbers of asbestos bodies extracted from the lungs of 103 patients with lung cancer and 50 patients with gastrointestinal malignant neoplasms were compared with the numbers of bodies extracted from the lungs of control patients matched for age, sex, smoking habits, and, in some cases, occupation. All patients were urban dwellers over the age of 40, and none was a primary asbestos worker. No differences in the counts of asbestos bodies were observed between the tested and control populations. The numbers of asbestos bodies did correlate well with occupation; the highest counts were found in male manual laborers. It is concluded that in the urban population studied, the numbers of asbestos bodies alone do not correlate with the presence of pulmonary or gastrointestinal carcinoma. However, uncoated asbestos fibers are also present in the lung, and the possibility that such tumors may be related to the numbers of these fibers in lungs remains to be explored. (25 refs)

- 79-6570 Influence of Dose and Fiber Type on Respiratory Malignancy Risk in Asbestos Cement Manufacturing. (Eng) Weill, H. (Dept. Medicine, Tulane Univ. Sch. Medicine, New Orleans, LA); Hughes, J.; Waggenspack, C. *Am Rev Respir Dis* 120(2): 345-354; 1979.

The risk of respiratory malignancy in relation to duration, degree, and type (fiber) of exposure to asbestos was studied based on a cohort of 5,645 men employed for at least 1 continuous mo before 1970 in either of two cement building materials plants in New Orleans and followed up for at least 20 yr. Cause-specific standard mortality ratios (SMR) increased slightly with degree of exposure, and the SMRs for respiratory system neoplasms exceeded 100 in men exposed to ≥ 101 million particles/ft³-yr (mppcf-yr). There was no excess mortality related to any cause other than respiratory neoplasms. Similar patterns were observed when the number of deaths expected on the basis of Louisiana death rates were used for comparison. Two pleural mesotheliomas were diagnosed, but both patients died prior to the end of the minimum 20-yr follow-up period. In men exposed to <101 mppcf-yr, the SMR for respiratory neoplasms did not change significantly with time since initial exposure, but the SMR increased with time since initial exposure in those exposed to ≥ 101 mppcf-yr. The mean total dust exposure was 164.1 mppcf-yr for the cancer patients in the cohort as compared with 77.8 mppcf-yr for control subjects ($p < 0.005$). The overall pattern of the odds ratio (an estimate of relative risk) was similar to that of the SMR for respiratory malignancy. The SMR for respiratory malignancy in nine duration-by-average-concentration categories generally indicated increasing risk with duration of employment and av concentration. The addition of crocidolite to chrysotile enhanced the risk for respiratory malignancy seen with chrysotile alone, especially in workers exposed intermittently to high concentrations of dust for short periods of time. (22 refs)

- 79-6571 Breast Cancer Mortality and Diet in the United States. (Eng) Gaskill, S. P. (Div. Clinical Epidemiology, Dept. Medicine, Univ. Texas Health Science Center at San Antonio, San Antonio, TX 78284); McGuire, W. L.; Osborne, C. K.; Stern, M. P. *Cancer Res* 39(9): 3628-3637; 1979.

Internationally, breast cancer (BC) mortality is correlated with intestinal lactase sufficiency and dairy product consumption beyond childhood. Within the US, age-adjusted BC mortality is positively

associated with consumption of milk, butter, and total milk fat in regional analyses, and it is associated with milk demand in state-based analyses. BC mortality is also positively associated with demand for total calories, protein, fat, beef, and table fats (butter and margarine), and it is negatively associated with egg demand. Only the associations with milk and egg demand, however, survive when the Southern states are eliminated from the analyses or when either age of first marriage or income is controlled. The associations with milk and egg demand persist despite multiple controls for other dietary and demographic variables, although the association with milk demand loses statistical significance in some second- and third-order partial correlations. The inverse correlation with egg demand is strong but in the opposite direction from what might have been expected from previous studies. The correlation between milk demand and BC mortality, although weaker, is consistent with results from previous studies, and it suggests a possible special role for dairy products in the etiology of BC. (68 refs)

- 79-6572 Breast Cancer in Surinam. (Eng) Brathwaite, A. F. (Academic Hosp. Paramaribo, Paramaribo, Surinam). *Trop Geogr Med* 31(1): 81-85; 1979.

The pathology of malignant lesions of the breast among residents of Surinam during 1964-1976 was studied retrospectively. Breast malignancies were diagnosed in 242 women and no men. The lesions were carcinomas in all but four patients, who had sarcoma. The mean age was 55.1 yr (range, 24-89 yr), and 45% of the patients were from the Creole population. The incidence during the study period was calculated as 9.5/100,000. Lymph node metastases, primarily to the axillary nodes, were confirmed in 85 patients with carcinoma. In the carcinoma patients, 115 tumors were in the left breast, 106 were in the right breast, and 17 were not localized as to side. (2 refs)

- 79-6573 "Incessant Ovulation" and Ovarian Cancer. (Eng) Casagrande, J. T. (Dept. Community and Family Medicine, Univ. Southern California Sch. Medicine, 2025 Zonal Ave., Los Angeles, CA 90033); Pike, M. C.; Ross, R. K.; Louie, E. W.; Roy, S.; Henderson, B. E. *Lancet* 2(8135): 170-173; 1979.

To determine the influence of fertility and oral contraceptive use on the risk of ovarian cancer, a case-control study was made of 150 ovarian cancer patients under the age of 50 and individually matched controls. The risk decreased with increasing numbers of live births, with increasing numbers of incomplete pregnancies, and with the use of oral contraceptives. These three factors can be combined into a single index of protection, "protected time," by considering them all as periods of anovulation. The complement of protected time [ie, "ovulatory age", the period between menarche and diagnosis of ovarian cancer (or cessation of menses) minus "protected time"] was strongly related to risk of ovarian cancer. Other factors found to be associated with increased ovarian cancer risk were obesity, cervical polyps, and gallbladder disease. Women who had an "immediate" intolerance to oral contraceptive use had a fourfold increased risk of ovarian cancer. Seven patients, but no controls, could recall a family history of ovarian cancer. (24 refs)

- 79-6574 Epidemiology of Hepatocellular Adenoma. The Role of Oral Contraceptive Use. (Eng) Rooks, J. B. (Office Population Affairs, Washington, DC); Ory, H. W.; Ishak, K. G.; Strauss, L. T.; Greenspan, J. R.; Hill, A. P.; Tyler, C. W. *JAMA* 242(7): 644-648; 1979.

A case-control study of the association between hepatocellular adenoma (HCA) and use of oral contraceptives (OC's) was conducted by interviewing 79 women with HCA and 220 age- and neighborhood-matched controls. Limited information was obtained for nine additional patients who had died. Women with HCA and hemorrhage have a greater risk of morbidity and death than those with other symptoms. Increasing duration of OC use increases the risk of HCA. Use of OC's with a high hormonal potency and age >30 yr may further increase a woman's risk of HCA. Long-term users of OC's have an estimated annual incidence of HCA of 3.4/100,000. (24 refs)

- 79-6575 Mutagens in the Feces of 3 South-African Populations at Different Levels of Risk for Colon Cancer. (Eng) Ehrlich, M. (Anaerobe Lab., Virginia Polytechnic Inst. and State Univ., Blacksburg, VA 24061); Aswell, J. E.; Van Tassell, R. L.; Wilkins, T. D.; Walker, A. R.; Richardson, N. J. *Mutat Res* 64(4): 231-240; 1979.

The incidence of mutagens in the feces of three South African populations at different risk levels for colon cancer, urban whites (high-risk population) and urban and rural blacks (2 low-risk populations), was determined. Lyophilized fecal samples were extracted with ether, and the mutagenicity of the extracts was determined in the *Salmonella*/mammalian microsome mutagenicity test. Nineteen percent of the samples from the urban whites were mutagenic using *Salmonella typhimurium* strain TA100. This incidence was significantly greater ($p < 0.001$) than the incidence of mutagen excretion in the urban blacks (2%) and rural blacks (0%). This pattern was also obtained using *S. typhimurium* strain TA98. The incidence of mutagen excretion for urban whites was 10%, compared with 5% and 2% for urban and rural blacks, respectively. (36 refs)

- 79-6576 An Analysis of the Mortality of Workers in a Nuclear Facility. (Eng) Gilbert, E. S. (Pacific Northwest Lab., Richland, WA 99352); Marks, S. *Radiat Res* 79(1): 122-148; 1979.

An analysis was made of data from the Hanford nuclear plant in Washington State, where many workers have been employed in jobs involving some exposure to radiation. Mortality from all causes, all cancers, and specific cancer types was related to personnel and exposure data for the population at risk. The mortality of the Hanford workers was first compared with that of the US population and then related to radiation exposure without reference to an outside population. The first analysis showed a substantial "healthy worker effect" and no significantly high standardized mortality ratios for specific disease categories. A test for association of mortality with levels of radiation exposure revealed no correlation for all causes and all cancers. A statistically significant test for trend was obtained for multiple myeloma and cancer of the pancreas, but no evidence of a positive correlation was found for 13 other cancer sites, including those more typically associated with radiation exposure such as myeloid leukemia and lung cancer. The possibility of other occupational exposures and the lack of reliability with respect to the diagnosis of pancreatic cancer must be considered in interpreting these results. The identified correlations resulted from a small number of deaths with exposures >15 rem (roentgen-equivalents-man). The lack of correlation for all cancers and for leukemia is not inconsistent with current estimates of such effects, given the amount of radiation exposure that had been received. (32 refs)

- 79-6577 Endometrial Carcinoma: The Effect of Estrogens. (Eng) Underwood, P. B. (Dept. Obstetrics and

Gynecology, Medical Univ. South Carolina, Charleston, SC 29403); Miller, M. C.; Kreutner, A.; Joyner, C. A.; Lutz, M. H. *Gynecol Oncol* 8(1): 60-73; 1979.

Three hundred seventy-three women with endometrial adenocarcinoma diagnosed at one medical center from August 1967 through February 1977 were studied according to their history of exogenous estrogen intake. Of the patients referred to as "estrogen users," 35% were or had been on some form of estrogen, with only 4% of the total population using estrogen <6 mo. Women with endometrial adenocarcinoma associated with exogenous estrogen ingestion were younger, thinner, and diagnosed at an earlier stage, and they had a more differentiated neoplasm, less myometrial invasion, and a better survival. Birth control pills could be associated with adenocarcinoma in only four of the estrogen users. (10 refs)

- 79-6578 A Catalog of Risks. (Eng) Cohen, B. L. (Dept. Physics and Astronomy, Univ. Pittsburgh, Pittsburgh, PA 15620); Lee, I. S. *Health Phys* 36(6): 707-722; 1979.

Information on risks from various sources was reviewed and converted into loss of life expectancy throughout life and in various age ranges. The risks include radiation, accidents of various types, various diseases, overweight, tobacco, alcohol, drugs, coffee, saccharin, birth control pills, occupational factors, socioeconomic factors, marital status, geography, service in the US armed forces in Vietnam, catastrophic events, energy production, and technology in general. Information is also included on methods for reducing risks, risks in individual actions, "very hazardous" activities, and priorities and perspective. Risks of natural and occupational radiation and exposure to radioactivity from the nuclear industry are compared with those of similar or competing activities. (46 refs)

- 79-6579 Differences in Age and Sex Distributions Among Patients with Non-Hodgkin's Lymphoma. (Eng) Elias, L. (Cancer Res. and Treatment Center, Univ. New Mexico, 900 Camino de Salud, NE, Albuquerque, NM 87131). *Cancer* 43(6): 2540-2546; 1979.

The records of 337 adult patients with non-Hodgkin's lymphoma seen at the Stanford University Medical Center were examined to determine whether there are any relationships between stage and histopathological classification and simple demographic characteristics (age and sex). Patients with Stages I and II disease and diffuse varieties of lymphoma were younger than patients in other categories. An excess of male patients was noted, particularly among younger patients with diffuse lymphoma and Stages I and II disease. Male patients with Stages I and II disease were bimodally distributed with respect to age, with peak numbers of patients occurring in the fourth and sixth decades. This was particularly apparent among patients with diffuse histiocytic lymphoma. (46 refs)

- 79-6580 Bladder Complications in Patients Receiving Cyclophosphamide for Systemic Lupus Erythematosus or Rheumatoid Arthritis. (Eng) Plotz, P. H. (Arthritis and Rheumatism Branch, Natl. Inst. Arthritis, Metabolism, and Digestive Diseases, NIH, Building 10, Room 9N210, Bethesda, MD 20205); Klippel, J. H.; Decker, J. L.; Grauman, D.; Wolff, B.; Brown, B. C.; Rutt, G. *Ann Intern Med* 91(2): 221-223; 1979.

The incidence of bladder complications in patients treated with cyclophosphamide (CP) for nonmalignant inflammatory rheumatic conditions was studied. Among 11 patients with rheumatoid arthritis treated with po CP, two cases of hemorrhagic cystitis and one case of widely metastatic bladder carcinoma without antecedent cystitis occurred. The cancer patient was a 70-yr-old woman who smoked cigarettes and had stopped taking CP 5 yr prior to the diagnosis of cancer. Among 43 lupus erythematosus (LE) cystitis patients treated with po CP, five had acute hemorrhagic cystitis, one of whom developed a papillary transitional cell carcinoma of the bladder. The carcinoma patient had experienced recurrent hematuria during CP therapy, and gross hematuria developed 28 mo after discontinuation of the drug treatment. The expected number of bladder carcinoma cases among the study population was 0.02, and the relative risk ratio was 100. No bladder complications occurred among 12 patients with LE treated with intermittent, iv CP or among 42 patients with lupus nephritis treated with azathioprine or corticosteroids alone. (10 refs)

- 79-6581 Opium: A Potential Urinary Bladder Carcinogen in Man. (Eng) Sadeghi, A. (Dept. Radiation Therapy, Nemazee Hosp., Shiraz, Iran); Behmard, S.; Vesselinovitch, S. D. *Cancer* 43(6): 2315-2321; 1979.

Evidence that opium addiction is a risk factor for cancer of the bladder is presented. A case-control study was made of 99 bladder cancer patients admitted to an Iranian hospital. Cancer patients and controls, matched by age and sex, were analyzed as to their opium and/or cigarette smoking habits. A high correlation between opium addiction and bladder cancer was observed. This correlation was significantly stronger than the one observed in relation to cigarette smoking only. The male:female sex ratio for this cancer site, based on hospitalized cases in Southern Iran, is approx 9:1. The high male:female ratio was attributed to the greater addiction of men to opium. It is concluded that opium and, more likely, its pyrolysis products may be potential bladder carcinogens in humans. (25 refs)

- 79-6582 Colorectal Carcinoids in South India. (Eng) Radhakrishnan, S. (Dept. Pathology, Thanjavur Medical Coll., Thanjavur, India); Subramoniam, S. *Trop Geogr Med* 31(1): 63-67; 1979.

The incidence of colorectal carcinoids among southern Indians was studied during 1965-1974. Seventeen men and three women with colorectal carcinoids were identified. They ranged in age from 20-65, but most were between 30 and 55. The most common site of involvement was the rectum, followed by the cecum, ascending colon, and hepatic flexure. Eight patients noticed a lump in the abdomen, 1 experienced recurrent intussusception, 10 had bloody stools, 9 had pain and vomiting, and 2 developed ascites. None had a carcinoid syndrome. Except for one case, all growths were single. The tumors were predominantly submucosal, and the majority were >2 cm in diameter. Only eight appendicular carcinoids were observed during the study period. The high incidence of colorectal carcinoids in this series of patients suggests a racial difference in organ susceptibility. (10 refs)

- 79-6583 Lung Cancer in Greater Bombay: Correlations with Religion and Smoking Habits. (Eng) Jussawalla, D. J. (Bombay Cancer Registry, Indian Cancer Society, Bombay, India); Jain, D. K. *Br J Cancer* 40(3): 437-448; 1979.

The resident population of Greater Bombay was analyzed for lung cancer incidence and other variables of possible significance to lung cancer incidence. During a 10-yr period from 1964-73, 2,177 lung cancer cases (1,861 males, 316 females) were registered from a population pool consisting of 5.24 million persons (3.07 million males, 2.17 million females). The av annual incidence of lung cancer was 13.6 per 10⁵ males but only 3.3 per 10⁵ females (age-adjusted to the Standard World Population). The incidence in non-Parsi males (14.0) was almost double the figure in Parsi males (6.8). However, there was no significant difference in incidence between non-Parsi (3.8) and Parsi females (3.3). Time-trend analyses did not reveal statistically significant differences in lung cancer incidence in any particular age group, male or female. The data from death certificates for the same 10-yr period showed that the age-adjusted rates were 11.0 and 3.3 per 10⁵ for males and females, respectively in the total population. In a retrospective study, 792 males with lung cancer (4.2% of 1,861 male cancer patients) for whom detailed smoking history was available were matched for age and community with randomly selected controls, obtained from the voters list of the Greater Bombay Corporation; and significant statistical association was found between tobacco smoking and lung cancer. All smokers appear to be at high risk (16.8) compared with nonsmokers. The relative risk for bidi smokers was 19.3, even higher than that for cigarette smokers (8.6). Hindu, Muslim and Christian smokers are apparently at identical risks. A dose-response relationship was found for bidi and cigarette smokers. (11 refs)

- 79-6584 Tar Exposure in Tobacco-associated Lung and Bladder Cancer. (Ger) Kunze, M. (Hygiene-Institut, Arbeitsgruppe Sozialmedizin der Universität, Kinderspitalgasse 15, A-1095 Vienna, Austria); Vutuc, C. *Munch Med Wochenschr* 121(32/33): 1041-1042; 1979.

A questionnaire study of smoking history was carried out in 200 men with lung cancer (group I) and 150 men with bladder cancer (group II). The av ages of men in groups I and II were 63.2 yr and 68.7 yr, respectively. Ninety-five percent of those in group I smoked cigarettes vs 87% of those in group II ($p < 0.01$). Cigarettes of high tar content (>25 mg) were currently smoked more frequently by group II patients than by group I ($p < 0.01$) patients. Group II patients had smoked an av of 2.5 yr longer than group I patients. These observations suggest that the critical amount of exposure to smoking producing bladder cancer is higher than that leading to lung cancer. The use of high tar cigarettes was more prevalent in both groups, compared with the general population. The av tar content of cigarettes produced in Austria was 33.7 mg in 1960, and declining to 18.3 mg in 1975. Since 1965, the av content has been <25 mg. Evidence for possible exposure to carcinogens at work was found in only 6% of the patients, indicating that smoking is a more important cause of bladder and lung cancer in Austria than is occupational carcinogen exposure. (8 refs)

- 79-6585 Mortality in Gold and Coal Miners in Western Australia with Special Reference to Lung Cancer. (Eng) Armstrong, B. K. (Public Health Dept., Western Australia, Australia); McNulty, J. C.; Levitt, L. J.; Williams, K. A.; Hobbs, M. S. *Br J Ind Med* 36(3): 199-205; 1979.

Cohorts of 1,974 gold miners and 213 coal miners in Western Australia were surveyed and followed up for 13-14 yr for respiratory symptoms, smoking habits, occupational history, and radiographic evidence of pneumoconiosis. Overall, neither group had a significantly higher mortality rate than expected from the experience of Western Australian men in general. Lung cancer mortality was relatively high in the gold miners (59 deaths observed,

40.8 expected) but weakly and inconclusively related to the extent of their underground mining experience. The excess of lung cancer in the gold miners may be attributable to cigarette smoking, which was more common among these miners (66.3%) than among the coal miners (58.7%) or the other men in Western Australia (53.2%). Radiographic evidence of silicosis was present in 21.7% of the gold miners but did not appear to have contributed substantially to their mortality. The coal miners showed a lower than expected rate of lung cancer but an excess of deaths from all other forms of cancer (11 observed, 5.6 expected). This excess was not specific to any one cancer site and could not be explained readily. (31 refs)

79-6586 Alimentary Tract Cancer in Australia in Relation to Diet and Alcohol. (Eng) McMichael, A. J. (Div. Human Nutrition, Commonwealth Scientific and Industrial Res. Organization, Kintore Ave., Adelaide, S. Australia 5000, Australia). *Nutr Cancer* 1(3): 82-89; 1979.

Time trends in cancer mortality and in the consumption of major foods and alcohol in Australia were examined. Although stomach cancer mortality has declined by about 65% since the 1920s, esophageal cancer mortality, initially steady, has subsequently declined and then increased again. The male/female ratios for stomach and esophageal cancer are 4:1 and 2:1, respectively. The declines in risk for both cancers occurred between successive generations. The generation born around 1870 experienced peak mortality from esophageal cancer at each age, whereas the generation immediately following initiated the decline at each age. The recent upswing in rates has been stronger among young age groups, suggesting the beginning of a second, generation-based increase. Consumption of alcoholic beverages was moderately high during 1910-1915, markedly lower through the 1920s, and has increased steadily since World War II. Since the 1930s, there has been about a 15% reduction in pulses and consumption of cereals, roots, and tubers. Refrigeration has improved, increasing the consumption of fruits and vegetables, and probably vitamins A and C. There has been a modest decline in dietary fiber intake but no increase in total or saturated fat or beef consumption. Allowing for a 10-20 yr cancer latency period, the time trends in the sex ratios of colorectal cancer mortality in Australia, England, and Wales have generally followed the beer consumption trends. For rectal cancer in men, the percentage change in mortality follows closely the percentage change in the immediately preceding beer consumption. The initially high incidence of colon and rectal cancer among migrants from Scotland and England declined with time spent in Australia, whereas the initially low incidence among migrants from Greece and Yugoslavia increased after migration to Australia. Stomach cancer risk generally decreased in migrants to Australia. Socioeconomic differences in gastrointestinal cancer risk within Australia are also apparent. (25 refs)

79-6587 The Association of Parity and Marital Status with the Development of Ovarian Carcinoma: Clinical Implications. (Eng) Demopoulos, R. I. (Dept. Pathology, New York Univ. Medical Center, 550 First Ave., New York, NY 1016); Seltzer, V.; Dubin, N.; Gutman, E. *Obstet Gynecol* 54(2): 150-155; 1979.

During 1962-1977, 327 patients with ovarian carcinoma were compared with matched controls to determine the association of parity and marital status with the development of this neoplasm. The relative risk of developing ovarian cancer was 2.31 times greater in nulliparous women than in parous women, and among parous women, the risk increased significantly with lower parity. The association with parity was generally similar in younger and older women and among patients from both low and high

socioeconomic levels. There was also a highly significantly greater risk of ovarian cancer among "never-married" women than among "ever-married" women, but there were no significant associations with religion. (25 refs)

79-6588 A Statistical Study of Sarcoma Complicating Paget's Disease of Bone in Three Countries. (Eng) Brackenridge, C. J. (National Res. Inst. Gerontology and Geriatric Medicine, Mount Royal Hosp., Parkville 3052, Australia). *Br J Cancer* 40(2): 194-200; 1979.

Data concerning sex, age at presentation and anatomical site of sarcoma complicating Paget's disease of bone were recorded from the literature for white patients in Australia, the United Kingdom and the US over the period 1918-77. Evidence is presented to suggest that sex and tumor-site distributions are free from bias, except, possibly, for the skull. There was a male predominance for all sites except the skull, for which the odds ratio of sarcoma compared with other locations was more than twice as high for women than for men. No national differences emerged in the sex ratio of the patients. In Australia, a latitudinal effect was observed. Although the percentage of men with uncomplicated Paget's disease was essentially constant, those with sarcoma showed a decrease with increase in latitude from Queensland to Victoria. This was attributable to tumors of the skull. Patients with bone involvement above the waist were significantly younger than those with affected feet, legs, or pelvic girdle. (28 refs)

79-6589 Childhood Lymphoma in Southern Iran. (Eng) Haghighi, P. (Dept. Pathology, Pahlavi Univ., Shiraz, Iran); Mostafavi, N.; Dezhbakhsh, F.; Ariazad, M.; Ghassemi, H.; Cook, A.; Salmassi, S.; Nabizadeh, I.; Asvadi, S. *Cancer* 44(1): 254-257; 1979.

A study was made of 81 childhood lymphomas diagnosed in the Department of Pathology of the Pahlavi University Medical Center, Shiraz, Iran. These disorders encompassed all histologically diagnosed childhood lymphomas from the Fars Province, Southern Iran, over a 14-yr period (1963-1976). There was a 3:1 male predominance and a 1:4 child/adult ratio. Peripheral lymphadenopathy at the initial physical examination was almost twice as common as deep node involvement. Comparison of cumulative and age-standardized (to world population) incidence rates with those of selected tumor registries in various continents revealed a higher rate of both non-Hodgkin's and Hodgkin's lymphoma in this region relative to some of the Western countries. The incidence rates were, in general, intermediate between Western populations on the one hand and some South American, African, and Asian populations on the other. Hodgkin's disease accounted for 64% (males) and 88% (females) of the lymphomas, and mixed cellularity was the commonest histologic subtype. Histologically, almost all the non-Hodgkin's lymphomas were diffuse at the time of diagnosis. (11 refs)

- 79-6590 Physico-chemical Studies of Isolated Chromatin Compared with In Situ Chromatin After Partial Hepatectomy in the Rat. (Eng) Miller, P. (Div. Biophysics, Temple Univ. Graduate Sch., Philadelphia, PA 19140); Linden, W. A.; Nicolini, C. *Z Naturforsch [C]* 34(5/6): 442-448; 1979.

The partially hepatectomized rat was used as an in vivo model to study changes in liver cell chromatin (CT) conformation after stimulation of the cells to proliferate. CT was isolated from rat liver cells at 0, 3, 5, 11, 18, and 24 hr following partial hepatectomy. Consistent with findings in cultured cells stimulated to proliferate, there was an increase in the molar ellipticity of CT measured at 276 nanometers, and a decrease in the thermal stability of CT 3-8 hr after surgery. These events occurred prior to the onset of DNA synthesis. The early changes between non-proliferating (G_0) and proliferating (G_1) cells, as well as later CT conformational changes observed at S and G_2 mimicked changes in template activity. The results with sheared and unsheared CT (both with in vitro and in vivo systems) proved that structural and functional changes can be caused by even the slightest shearing during CT preparation, suggesting the loss of native CT organization. To eliminate this problem, experiments were also conducted using CT in situ. A flow cytometer (FCM) was used to study unfixed liver cell suspensions stained with ethidium bromide (EB). Fluorescence was measured in the green spectral range after the addition of increasing amounts of EB. The same alteration in CT conformation was best detected using low molar ratios of EB per unit DNA, because of the greater fluorescence emission in G_1 than in G_0 cells. These correlated studies demonstrate that the same changes controlling CT organization in situ are detected also in the tertiary-quaternary structure of isolated CT. These changes in CT conformation are macromolecular events related to cell proliferation both at the G_0 - G_1 and G_1 -S transitions. (27 refs)

- 79-6591 A Hydroxylapatite Batch Assay for Quantitation of Cellular DNA Damage. (Eng) Kanter, P. M. (Dept. Experimental Therapeutics, Grace Cancer Drug Center, New York State Dept. Health, Roswell Park Memorial Inst., Buffalo, NY 14263); Schwartz, H. S. *Anal Biochem* 97(1): 77-84; 1979.

DNA damage was measured quantitatively by a batch elution procedure based on alkaline unwinding of cellular DNA and separation of single-stranded from duplex forms by step elution from hydroxylapatite with phosphate formamide. The method is rapid, permits large numbers of samples to be handled simultaneously, and consistently yields recoveries of >95% of total chromatographed DNA. Because as many as 1×10^7 cells per batch may be analyzed, quantitation of the eluted DNA by nonradioactive methods is feasible. The method is standardized with respect to the unwinding constant β , the alkaline DNA unwinding unit Mn_0 , and the DNA-damaging efficiency of ionizing irradiation. (19 refs)

- 79-6592 Metabolic Utilization of Arginine by Acute Myeloid Leukemia Cells. (Pol) Hansz, J. (Klinika Hematologii, Instytutu Chorob Wewnętrznych Akademii Medycznej, ul. Szkolna 8/12, 61-833 Poznan, Poland). *Pol Arch Med Wewn* 61(2): 113-120; 1979.

The metabolism of ^{14}C -arginine by acute myeloid leukemia cells and by normal granulocytes was compared. The results showed that the leukemic cells incorporated much more of the amino acid into their protein than the normal granulocytes. The highest activity was demonstrated by cells from the blastic crisis of chronic myeloid leukemia. The amount of ^{14}C -arginine incorporated into the leukemic cell protein depended to a considerable extent on the degree of cell maturation; ie, the blast cells incorporated more than the mature WBC. The results indicate that leukemic transformation is associated with an increased metabolic requirement for arginine. (16 refs)

- 79-6593 Lectin-mediated Agglutination of Murine Lymphoma Cells. Cell Surface Deformability and Reversibility of Agglutination by Saccharides. (Eng) Nicolson, G. L. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA 92717); Poste, G. *Biochim Biophys Acta* 554(2): 520-531; 1979.

The secondary effects occurring during the lectin-mediated cell agglutination of a murine S49 lymphoma cell line that grows as isolated cells in suspension and does not establish cell-to-cell adhesions were studied. When S49 cells were agglutinated by *Ricinus communis* 1 lectin, agglutination occurred in a dose- and temperature-dependent fashion. The multicell aggregates thus formed could be dispersed by treatment with lactose [50-100 millimolar (mM)], but only if it was added immediately after removal of the lectin. The irreversibility of S49 cell agglutination was dependent on time, temperature, and lectin concentration; and its onset was correlated with ultrastructural deformations of adjacent cell surfaces and increases in the proportion of adjacent cell surface areas in close apposition with multicell aggregates. Cytochalasin B (CB, 10-20 μ g/ml) enhanced S49 agglutination by *R. communis* 1 agglutinin, whereas vinblastine sulfate (VS, 1-10 μ M) and preincubation of the S49 cells with sodium fluoride (SF, 5 mM) plus sodium azide (SA, 2 mM) had no effect. VS or VS plus CB inhibited lactose dispersal of the S49 multicell aggregates, while SF plus SA enhanced hapten reversibility. The onset of agglutination irreversibility correlated with cell surface deformation in the drug-treated cells. Cell aggregates that were more readily reversible by lactose were unchanged or less deformed, whereas those treated with CB plus VS were more deformed compared with controls. The data suggest a role for cell surface deformability as an important secondary effect during lectin-mediated cell agglutination of S49 cells. (40 refs)

- 79-6594 Sequence Complexity of Transcribed Unique DNA Sequences in Mouse P815 Mastocytoma Cells. (Ger) Boehm, T. L. (Zentrum der Biologischen Chemie, Universitat Frankfurt am Main, Theodor-Stern-Kai 7, 6000 Frankfurt am Main 70, W. Germany); Drahovsky, D. *Z Naturforsch [C]* 34(5/6): 436-441; 1979.

The sequence complexity of nuclear RNA (nRNA) from mouse liver, spleen, and mastocytoma P815 cells was measured by hybridization of nRNA to unique DNA sequences of the P815 cells. Assuming asymmetrical transcription, the complexities of the transcripts were 2.8×10^6 nucleotides for the P815 mastocytoma, 4.3×10^6 for the spleen, and about 5.3×10^6 nucleotides for the liver. (13 refs)

- 79-6595 **Enhancing Effect of Thyroxine on Tumor Growth and Metastases in Syngeneic Mouse Tumor Systems.** (Eng) Kumar, M. S. (Dept. Immunopathology, Cleveland Clinic Foundation, Cleveland, OH 44106); Chiang, T.; Deodhar, S. D. *Cancer Res* 39(9): 3515-3518; 1979.

The effect of synthetic L-thyroxine (TX) treatment on tumor growth and metastases resulting from tumor implants on the hind feet of mice was studied in two syngeneic systems. In control untreated A/Jax mice, sarcoma 1 at day 4 after implantation had an av tumor wt of 582 ± 60 (SD) mg and showed an incidence of 57% metastases to regional popliteal nodes and 5% metastases to the thymus. In contrast, the TX-treated group ($40 \mu\text{g}/\text{mouse}$ sc, 5 times/wk for 1 mo) had an av tumor wt of 808 ± 56 mg ($p < 0.001$), and metastases to popliteal nodes and thymus were 90% and 35%, respectively. In another syngeneic tumor system, Lewis fibrosarcoma was implanted in C57BL/6J mice, and the tumor wt and metastatic index (derived from the number and size of the pulmonary tumor foci) were determined at Day 28. Again, the TX-treated group showed a significant enhancement of tumor growth and metastatic index. The mean tumor wt in the treated group was 835 ± 26 mg (control, 694 ± 25 mg; $p < 0.005$), and the metastatic index was 84 ± 29 (control, 30 ± 25 ; $p < 0.001$). Induced hypothyroidism (treatment with ^{131}I , $100 \mu\text{Ci}/\text{mouse}$ ip) showed the reverse effect on both tumor systems. These results suggest that both tumor systems are dependent on thyroid hormones for their growth and spread. (22 refs)

- 79-6596 **Correlation of Glycosylation in a Membrane Protein with a Molecular Weight of 150,000 with Tumorigenic Property of Rat Fibrosarcoma Variants.** (Eng) Koyama, K. (Div. Biochemical Oncology, Fred Hutchinson Cancer Res. Center, Seattle, WA 98104); Nudelman, E.; Fukuda, M.; Hakomori, S. *Cancer Res* 39(9): 3677-3682; 1979.

An attempt was made to correlate the status of glycosylation in a 150,000-dalton membrane protein with the tumorigenicity of rat fibrosarcoma variants. Four clonal variants with differing degrees of tumorigenicity and intercellular adhesiveness were isolated from a tumor induced by methylcholanthrene in inbred Donryu rats. Variant clones G and Z were characterized by an extremely low tumorigenicity, in contrast to the high tumorigenicity of the original clone A and variant clone P. P was highly tumorigenic in ascites form when inoculated ip, but its tumorigenicity was minimal when inoculated sc. Under the scanning electron microscope, sharp, well-developed microvilli were observed on the surface of Z and G, in contrast to the smooth blebs found on the surface of A and P. G cells and, to a lesser extent, Z cells showed a remarkable side-by-side adherence, thereby forming a wormlike shape and sharing a common cell coat. A and P were not adherent. Protein and glycoprotein profiles of these variant cell lines were studied by the following surface-labeling techniques: lactoperoxidase-catalyzed [^{125}I]iodination, galactose oxidase- NaB^3H_4 , periodate- NaB^3H_4 , and by metabolic labeling with precursor sugars. The variant cell lines showed a remarkable difference in degree of sialylation in one glycoprotein species with a relative mol wt of 150,000, whereas the profiles of other proteins and glycoproteins were indistinguishable among the lines. The status of glycosylation in this unique 150,000-dalton glycoprotein may reflect the tumorigenicity of the four variant isolates. (29 refs)

- 79-6597 **Synthesis of α -Fetoprotein, Albumin, and Transferrin in Continuous Murine Hepatoma Cell Lines.** (Rus) Aleksanian, Iu. T. (Lab. Molecular Basis Immunogenesis, Inst.

Experimental Biology, Erevan, USSR). *Biull Eksp Biol Med* 88(7): 76-77; 1979.

This study was designed to determine whether murine hepatoma XXIIa cells continuously cultured in vitro retain the capability to synthesize marker serum proteins. An indirect radioimmunoassay revealed that 5-yr cultures contained albumin and transferrin, but no α -fetoprotein (AFP). Eight-yr cultures contained only transferrin. Inoculation of C3HA mice with both 5- and 8-yr cells (10^5 - 10^6 cells/mouse) resulted in tumor development, which indicated that continuously cultured cells retained tumorigenic activity. The serum of mice inoculated with 5-yr cells contained AFP, but not the serum of mice inoculated with 8-yr cells. These findings indicate that the loss of AFP in 5-yr cultures is reversible. (11 refs)

- 79-6598 **Repression, Derepression, Transinhibition, and Trans-stimulation of Amino Acid Transport in Rat Hepatocytes and Four Rat Hepatoma Cell Lines in Culture.** (Eng) Kelley, D. S. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Potter, V. R. *J Biol Chem* 254(14): 6691-6697; 1979.

The effects of amino acid depletion and supplementation on the transport of amino acids in four hepatoma cell lines (HTC, H-35, 7777, and 8994) were compared with the effects in hepatocytes. In both the hepatocytes and hepatoma cell lines, amino acid starvation caused a five- to eightfold increase in the sodium-dependent transport of 2-aminoisobutyric acid (AIB) without affecting the sodium-independent transport. The hepatoma cell lines reached the max level of AIB uptake within 12 hr of amino acid starvation, maintained this level for 12 hr, and showed a considerable increase in the uptake of leucine. The hepatocytes reached the max level of AIB uptake within 24 hr of amino acid starvation, maintained this activity for 24 hr, and showed only a moderate increase in leucine uptake. The increase in the activity of the A system resulting from amino acid starvation could be blocked by actinomycin D or cycloheximide. AIB added to the starvation medium completely blocked the increase in the activity of the A system in hepatocytes and three of the hepatoma lines, but there was a slight increase in AIB uptake by H-35. In both the hepatocytes and hepatoma lines, the increase in activity of the A system was due to derepression and to release from transinhibition of the transport system. Conversely, the decrease in the activity of the A system caused by the addition of amino acids to the starved cultures was due to repression and transinhibition. (23 refs)

- 79-6599 **Two Polypeptide Changes Associated with Butyric Acid Resistance and the Neoplastic State of Syrian Hamster Cells.** (Eng) Leavitt, J. (Div. Virology, Bureau Biologics, Food and Drug Admin., Bethesda, MD 20014). *Biochim Biophys Acta* 563(1): 227-239; 1979.

Qualitative polypeptide differences between parental Syrian hamster embryo cells and nine independently established neoplastic cell lines transformed by chemical carcinogen treatment, virus infection, or an unknown spontaneous event were examined. Although no perfect correlation with a specific polypeptide change was found, two polypeptide changes, occurring independently or simultaneously, appeared to be consistently associated with expression of neoplasticity. One polypeptide species designated τ , having an isoelectric point of 4.6 and a mol wt of 60,000, was lost or physically altered in all but one of these transformed cell lines; a second polypeptide species designated ν , having an isoelectric point of 5.5 and a mol wt of 42,000, appeared in highly tumorigenic chemically transformed cell lines and in two

virally transformed cell lines. A butyric acid supplement, used as a selective agent for butyric acid-resistant cells, was employed to identify and isolate in a single step nascent neoplastic clonal lines transformed by ethyl methanesulfonate. These cell lines exhibited alterations in τ or ν . The changes observed in τ were consistent with those expected to result from a somatic mutation in the structural gene coding for τ ; however, the alterations in τ could also be governed by a posttranslational process. These findings suggest that alterations in the expression of at least two major polypeptide species, τ and ν , are closely associated with primary steps in the neoplastic transformation of Syrian hamster cells, irrespective of the nature of the transforming agent. - 79-6600 Histone Acetylation in CV-1 Cells Infected with Simian Virus 40. (Eng) La Bella, F. (Lab. Cell Biology

CNR, Via Romagnosi 18A, 00196 Rome, Italy); Vidali, G.; Vesco, C. *Virology* 96(2): 564-575; 1979.

The histone acetylation of host cell chromatin was compared with that of intracellular 70S minichromosomes in CV-1 monkey kidney cells infected with simian virus 40 (SV40). The degree of acetylation in the histones of cell chromatin did not substantially increase after infection; the 70S minichromosomes contained histones that were not as highly acetylated as those contained in virions, but more acetylated than those associated with the infected cell chromatin. The rate of acetylation, as measured by [3 H]acetate uptake, appeared to be nearly equal for the histones associated with viral and cellular DNA. The acetyl groups incorporated by the 70S histones, however, were retained in larger proportion compared with those incorporated by the host histones. (32 refs)

LIBRARY U. OF I. URBANA - CHAMPAIGN

Subject Index

Abdominal Neoplasms
 Burkitt's Lymphoma
 Nonendemic Disease, 79-6524
 Lymphangioma
 Radiation, Ionizing, 79-6370
 Lymphangiosarcoma
 Neoplasm Recurrence, Local, 79-6370

Abnormalities
 Nephroblastoma
 Neoplasms, Multiple Primary, 79-6546
 Sex Hormones
 Epidemiology, Review, 79-6116
 Teratogenic Effect, Review, 79-6116
 4,4'-Stilbenediol, α,α' -Diethyl-
 Epidemiology, Review, 79-6025

Acetamide, N-Fluoren-2-yl-
 Ames Test
 Mutagenic Activity, 79-6169
 Mutagenic Metabolite, 79-6167
 S9 Fraction, Guinea Pig, 79-6166
 7,8-Benzoflavone
 Ames Test, 79-6166
 Cytochrome P-450
 Ames Test, 79-6166
 Dimethylamine, N-Nitroso-
 DNA Repair, 79-6170
 Guanine, 7-Methyl-
 DNA Repair, 79-6170
 Hepatoma
 Alpha Fetoproteins, 79-6172
 Neoplasm Transplantation, 79-6172
 Microsomes, Liver
 Mutagenic Metabolite, 79-6167
 Peptides, 79-6167
 NADPH Cytochrome C Reductase
 Ames Test, 79-6166
 Photosensitive Analogs
 Carcinogenic Potential, 79-6139
 Purine, 2-Amino-6-methoxy-
 DNA Repair, 79-6170
 Liver, Rat, 79-6170

Acetamide, N,N'-Fluorene-2,7-diylbis-
 Liver Neoplasms
 Histochemical Study, Peroxisomes
 79-6171
 Precancerous Conditions, 79-6171

Acetamide, N-(7-Hydroxyfluoren-2-yl)-
 Aryl Hydrocarbon Hydroxylases
 Microsomes, Liver, 79-6167

Acetanilide, 4'-Hydroxy-
 Cysteine
 Hepatotoxic Metabolite, Review
 79-6007
 Glutathione
 Hepatotoxic Metabolite, Review
 79-6007

**Acetic Acid, (Ethylenebis(oxyethylenetri-
 lilo))tetra-**
 Glioma
 Calcium, 79-6164

**Acetic Acid, Methylnitrosaminomethyl Es-
 ter**
 Mutagenic Metabolite
 Tissue Specificity, 79-6165
 Pyrazole
 Toxicity, Rat, 79-6148

Acetohydroxamic Acid, N-4-Biphenyl-
 Acyltransferases
 Mammæ, Rat, 79-6173

Acetohydroxamic Acid, N-Fluoren-2-yl-
 Acyltransferases
 Mammæ, Rat, 79-6173
 RNA, Ribosomal, Binding, 79-6173
 Aryl Hydrocarbon Hydroxylases
 Microsomes, Liver, 79-6167
 Chromatin

Acetohydroxamic Acid, N-Fluoren-2-yl-
 (cont'd)
 Binding Sites, Liver, 79-6168
 DNA Adduct, 79-6168
 Metabolism
 Pharmacokinetics, Review, 79-6008

Acetonitrile, 2,2'-Iminobis-
 Ascorbic Acid
 Nitrosation, 79-6245

p-Acetophenetidine
 Glutathione
 Hepatotoxic Metabolite, Review
 79-6007
 Metabolism
 Pharmacokinetics, Review, 79-6008

Acetyl Chloride, Dichloro-
 Ethylene, Trichloro-
 Epoxide Metabolites, 79-6151

Achlorhydria
 Stomach Neoplasms
 Epidemiology, 79-6561

Acid Phosphatase
 Glioma
 Enzymatic Activity, 79-6201
 Leukemia, Hairy Cell
 Diagnosis, 79-6482
 Phagocytosis, 79-6525

Acridine
 DNA Repair
 Carcinogenic Potential, Review
 79-6013
 Mutation
 Genetic Effects, Review, 79-6013

Acridine, 9-Amino-
 Poly U
 DNA, Binding, 79-6265

Acridine, 3,6-Bis(dimethylamino)-
 Poly U
 DNA, Binding, 79-6265

Acridine, 3,6-Diamino-
 Carcinosarcoma
 Light, 79-6287
 Lymphoma
 Light, 79-6287
 Mammary Neoplasms, Experimental
 Light, 79-6287
 Poly U
 DNA, Binding, 79-6265
 Skin Neoplasms
 Light, 79-6287

Acridino(2,1,9-mna)acridine
 Carcinogenic Activity
 Polarographic Behavior, 79-6330

Acrolein, 2-Chloro-
 Carbamic Acid, Diisopropylthio-, S-(2,3-
 Dichloroallyl) Ester
 Mutagenic Metabolite, 79-6056

Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-
 Ames Test
 Mutagenic Activity, Review, 79-6046

Acrylonitrile
 Brain Neoplasms
 Carcinogenic Activity, Rat, 79-6181
 Occupational Hazard
 Risk Factors, 79-6181

Actinomycin D
 Amino Acids
 Liver, Rat, 79-6598

Acyltransferases
 Acetohydroxamic Acid, N-4-Biphenyl-
 Mammæ, Rat, 79-6173
 Acetohydroxamic Acid, N-Fluoren-2-yl-

Acyltransferases (cont'd)
 Mammæ, Rat, 79-6173
 RNA, Ribosomal, Binding, 79-6173

Adenine Nucleotides
Agrobacterium tumefaciens
 Bacteriocins, 79-6230

Adenocarcinoma
 Colonic Neoplasms
 Hydrazine, 1,2-Dimethyl-, 79-6177
 Immunity, Cellular, Review, 79-6087
 Immunotherapy, Review, 79-6087
 Urea, Methyl Nitroso-, 79-6208
 Dipropylamine, 2-Hydroxy-N-nitroso-2'-
 oxo-
 Neoplasm Metastasis, 79-6196
 Ear Neoplasms
 Pectin, 79-6176
 Guanidine, 1-Methyl-3-nitro-1-nitroso-
 Age Factors, Rat, 79-6223
 Cells, Cultured, 79-6220
 Precancerous Conditions, 79-6221
 Gynecologic Neoplasms
 Hemorrhage, 79-6551
 Hydrazine, 1,2-Dimethyl-
 Nucleoproteins, 79-6177
 Pectin, 79-6176
 Intestinal Neoplasms
 Hydrazine, 1,2-Dimethyl-, 79-6175
 79-6176
 Polyps, 79-6175
 Kidney Neoplasms
 Anthraquinone, 1-Amino-2-methyl-
 79-6262
 T-Lymphocytes
 Antibody Formation, 79-6517
 79-6518
 Hypersensitivity, 79-6517, 79-6518
 Lymphocyte Depletion, 79-6517
 79-6518
 Neoplasm Metastasis, 79-6517
 Mammary Neoplasms, Experimental
 Antibody-Dependent Cell Cytotoxicity
 79-6518
 Benz(a)anthracene, 7,12-Dimethyl-
 79-6299
 Lymphocyte Depletion, 79-6517
 79-6518
 Neoplasm Metastasis, 79-6517
 Radiation, Ionizing, 79-6299, 79-6517
 79-6518
 p-Toluamide, N-Isopropyl- α -(2-
 methylhydrazino)-, 79-6299
 Virus, Murine Mammary Tumor
 79-6396
 Water Pollutants, 79-6343, 79-6344
 Ovarian Neoplasms
 Water Pollutants, 79-6343
 Pancreatic Neoplasms
 Dipropylamine, 2-Hydroxy-N-nitroso-
 2'-oxo-, 79-6196
 Prostatic Neoplasms
 Androst-4-ene-3,17-dione, 79-6351
 Precancerous Conditions, 79-6553
 Testosterone, 79-6351
 Psoralen, 8-Methoxy-
 Ultraviolet Rays, 79-6287
 Radiation, Ionizing
 Hypersensitivity, 79-6518
 Neoplasm Metastasis, 79-6517
 4,4'-Stilbenediol, α,α' -Diethyl-
 Epidemiology, Review, 79-6025
 Stomach Neoplasms
 Guanidine, 1-Methyl-3-nitro-1-nitroso-
 79-6221, 79-6222, 79-6223
 Propionic Acid, 2-(p-Chlorophenoxy)-
 2-methyl-, Ethyl Ester, 79-6153
 Urea, 1-(2-Chloroethyl)-3-(2-
 hydroxyethyl)-1-nitroso-
 Drug Therapy, 79-6211
 Urogenital Neoplasms
 Propionic Acid, 2-(p-Chlorophenoxy)-

Adenocarcinoma (cont'd)
 2-methyl-, Ethyl Ester, 79-6153
Uterine Neoplasms
 Adenosine, Methyl Nitroso-, 79-6232
 Case Report, Ovariectomy, 79-6552
 Contraceptives, Oral, 79-6577
 Estrogens, 79-6567, 79-6577
 Estrone, 79-6028
 FSH, 79-6552
 LH, 79-6552
 Progesterational Hormones, 79-6028
 Receptors, Hormone, Review, 79-6028
Vaginal Neoplasms
 Epidemiology, Review, 79-6125
 4,4'-Stilbenediol, α,α' -Diethyl-, 79-6125
 Virus, Murine Mammary Tumor
 Antigens, Viral, 79-6396

Adenofibroma
 Mammary Neoplasms, Experimental
 Radiation, Ionizing, 79-6299
 Morpholine, *N*-Nitroso-
 Carcinogenic Activity, Rat, 79-6215

Adenolymphoma
 Cell Transformation, Neoplastic
 Case Report, 79-6519

Adenoma
Adrenal Gland Neoplasms
 Strain Difference, Hamster, 79-6544
Colonic Neoplasms
 Urea, Methyl Nitroso-, 79-6208
Gastrointestinal Neoplasms
 Precancerous Conditions, Review
 79-6101
IgG
 Antigen-Antibody Complex, 79-6505
Intestinal Neoplasms
 Hydrazine, 1,2-Dimethyl-, 79-6176
Liver Neoplasms
 Phorbol, 79-6189
 Phorbol, 12-Deoxy-, 79-6189
Lung Neoplasms
 Benzo(a)pyrene, 7,8-Dihydro-7,8-dihydroxy-, 79-6017
 Cholanthren-2-ol, 3-Methyl-, 79-6308
 Cholanthren-2-one, 3-Methyl-, 79-6308
 Cholanthrene, 9,10-Dihydro-3-methyl-1,9,10-trihydroxy-, 79-6308
 Mouse, 79-6541
 Phorbol, 79-6266
Pancreatic Neoplasms
 Propionic Acid, 2-(*p*-Chlorophenoxy)-2-methyl-, Ethyl Ester, 79-6153
Pituitary Neoplasms
 Imidazole-1-ethanol, 2-Methyl-5-nitro-79-6216
Stomach Neoplasms
 Classification, Review, 79-6094
 Guanidine, 1-Methyl-3-nitro-1-nitroso-79-6222
Thyroid Neoplasms
 Radiation, Ionizing, 79-6113, 79-6368
 Strain Difference, Hamster, 79-6544

Adenomatosis, Familial Endocrine
 Carcinoid Tumor
 Genetics, Review, 79-6093
Gastrointestinal Neoplasms
 Epidemiology, Review, 79-6100
Parathyroid Neoplasms
 Genetics, Review, 79-6093
Thyroid Neoplasms
 Genetics, Review, 79-6093

Adenosine Cyclic 3',5' Monophosphate
 Glioma
 Calcium, 79-6164
 Norepinephrine, 79-6164
Mesothelioma
 Asbestos, 79-6231

Adenosine, Methyl Nitroso-
 Lung Neoplasms
 Carcinogenic Activity, Mouse, 79-6232
 Mammary Neoplasms, Experimental

Adenosine, Methyl Nitroso- (cont'd)
 Carcinoma, 79-6232
Nitrous Acid
 Carcinogenic Activity, Mouse, 79-6232
 Nucleoside Interaction, 79-6232
Uterine Neoplasms
 Adenocarcinoma, 79-6232

Adenosine Triphosphatase
 Virus, SV40
 Antigens, Neoplasm, 79-6441

Adrenal Cortex
 Kepone

Dietary Fats

Benz(a)anthracene, 7,12-Dimethyl-

Dietary Fats (cont'd)

- Microsomes, Liver, 79-6301
- Concanavalin A
- Lymphocyte Transformation, 79-6516
- Hepatoma
- Aflatoxin B1, 79-6279
- Intestinal Neoplasms
- Epidemiology, Review, 79-6114
- Mammary Neoplasms, Experimental
- Benz(a)anthracene, 7,12-Dimethyl-79-6301, 79-6516
- Neoplasms
- Epidemiology, Review, 79-6026

Dietary Fiber

- Colonic Neoplasms
- Methane, Azoxy-, 79-6204
- Urea, Methyl Nitroso-, 79-6204
- Intestinal Neoplasms
- Epidemiology, Britain, 79-6559
- Hydrazine, 1,2-Dimethyl-, 79-6176
- Pentoses, 79-6559

Dietary Proteins

- Aflatoxin B1
- Alkaline Phosphatase, 79-6280
- Aminotransferases, 79-6280
- Lactate Dehydrogenase, 79-6280
- Aflatoxin M1
- Metabolism, Rat, 79-6280
- Aflatoxin P1
- Metabolism, Rat, 79-6280

Diethylamine, 2,2'-Dichloro-N-methyl-

- Mutation
- Yeasts, 79-6191

Diethylamine, N-Nitroso-

- Cell Transformation, Neoplastic
- Carcinogenic Metabolite, 79-6288
- Tissue Culture, 79-6195
- Chromosome Aberrations
- Drosophila melanogaster*, 79-6205
- 79-6209
- Cytochalasin B
- Cell Transformation, Neoplastic
- 79-6195
- DNA Polymerase
- DNA Repair, 79-6190
- DNA Replication, 79-6190
- Precancerous Conditions, 79-6190
- DNA Repair
- Hepatocarcinogenicity, 79-6184
- Liver, Rat, 79-6184
- Esophageal Neoplasms

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with The Franklin Institute Research Laboratories for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by The Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 17, consisting of 12 monthly issues and a cumulative index, is \$90.00 U.S., Canada and Mexico and \$120.00 foreign. Individual issues will be charged at \$10.00 to subscribers, \$15.00 each to non-subscribers. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 17, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)
bid	twice daily	mol wt	molecular weight
C	degree(s) centigrade	N	normal concentration
cal	calorie(s)	NAD	nicotinamide adenine dinucleotide
kcal	kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
Ci	curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
mCi	millicurie(s)	NCI	National Cancer Institute
μCi	microcurie(s)	NIH	National Institutes of Health

Notice To Our Readers

CARCINOGENESIS ABSTRACTS will cease publication after the completion of Volume 17. Issue 12 will be the last issue of abstracts which will be followed by a separate cumulative index.

LIBRARY U. OF I. URBANA - CHAMPAIGN

REVIEW

- 79-6601 Cancer Development from the Viewpoint of Molecular Biology. (Ger) Popp, F. A. (Radiologiezentrum der Universität, Lahnstrasse 4a, 3500 Marburg, W. Germany). *Krebsgeschehen* 11(2): 48-51; 1979.

The tendency of scientists to adopt a "local" viewpoint in cancer research, ie, to interpret carcinogenesis as a cellular defect rather than as a defect in a tissue as a whole, is criticized, and a theory of "non-local" carcinogenesis is presented. The theory is based on the observation that, within a group of biologically active molecules, the activity depends on resonance-coupling to an electromagnetic (photon) field. This electromagnetic field is considered to be a property of tissue, not of single cells. According to the model, photon-emission (Ph-E) from growing tissue is higher than that from mature tissue. Photon-absorption occurs also, so that equilibrium is maintained. However, dying cells emit, but do not absorb, photons, a condition thought to stimulate repair. Tumor cells are thought to have reduced ability to absorb photons, compared with normal growing tissue. Thus, cancer tissue is on the photon-emitting side of equilibrium. The Ph-E curves of Ehrlich-ascites tumor cells treated with different concentrations of 4-hydroperoxycyclophosphamide show a lack of photon absorption ability, compared with normal cells. The ability of chemotherapeutic drugs to normalize photon absorption in biopsy specimens of a given tumor should be tested; this is recommended as a method of providing more individualized treatment. (28 refs)

- 79-6602 Problems and Perspectives in Perinatal Carcinogenesis: A Summary of the Conference. (Eng) Rice, J. M. (Experimental Pathology Branch, NCI, Bldg. 37, Room 3A09, Bethesda, MD 20205). *Natl Cancer Inst Monogr* (51): 271-278; 1979.

A major stimulus for the study of perinatal carcinogenesis has been the concept that the fetal and neonatal periods are times of high susceptibility to carcinogens. No known carcinogen acts exclusively in the fetus or neonate, but some agents show a greater effect in the fetus or neonate than in the adult. Diethylstilbestrol, for example, induces change in the human fetus leading to carcinogenesis but is not carcinogenic in the adult female. Estrogens are, however, carcinogenic in adult rodents. The state of differentiation of the murine female reproductive tract is critical for the induction of modifications in function by exogenous hormones. High perinatal susceptibility to hormones is inherent in the undifferentiated state, but susceptibility to nonhormonal carcinogens tends to increase with increasing differentiation. Most chemical carcinogens require enzyme-mediated metabolism for conversion to the active state. Decreased fetal response to some carcinogens is due to lack of metabolizing enzymes in fetal tissue. A rapid bioassay involving in utero exposure to a carcinogen followed by cell culture studies to reveal transformed cells has helped elucidate potential in vivo control mechanisms in tumor development. The immune system may either enhance or inhibit these processes. The direct-acting alkylating agents are the most potent transplacental carcinogens, partly because they are independent of enzyme-mediated metabolism. Their carcinogenic effects are often restricted to certain organ systems, and different organ systems are affected in different species. Undifferentiated embryonic tissues are resistant even to these agents. Some human tumors are rarely

found in rodents. An increased tumor risk has been found in offspring of animals treated in utero. The refractory nature of undifferentiated tissue has also been found to apply to oncogenic viruses. Most tumors induced transplacentally or neonatally in rodents are histologically identical to human adult but not infant tumors. It is stressed that more than one species should be studied and comparisons made between these species. (17 refs)

- 79-6603 The Problem of Estimating Safe Dose Levels in Chemical Carcinogenesis. (Eng) Wahrendorf, J. (Institut für Dokumentation, Information und Statistik, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, D-6900 Heidelberg 1, W. Germany). *J Cancer Res Clin Oncol* 95(2): 101-107; 1979.

Various methods of determining safe dosages of chemical carcinogens are summarized with respect to models for tumor rates and models for failure times. Three different mathematical models for tumor rates (dose-effect) are discussed in terms of rationale, advantages and disadvantages, and correlation with experimental data. The log-probit model is based on the assumption that there is a tolerance level for a carcinogen that shows a random variation according to a log-normal distribution among the individuals examined. The log-logistic model differs from the log-probit model only in that the logit-transform of the effect shows a linear dependence on the logarithm of the dose. The multi-stage model assumes that the carcinogenic process takes place in an integral number of steps that may be induced spontaneously or as a result of the dose administered; this is expressed mathematically so that the probability of developing a tumor decreases exponentially towards zero with decreasing dose. A table is presented that lists the expected probabilities of response for these three models over a wide dose range. Models for failure time are discussed with regard to the necessity for consideration of the toxicity of a substance and the survival patterns of animals in which it is tested. One example of a stochastic model for failure times is described in detail, with discussion of the probability distribution of time of incidence, the use of the multi-stage model for the dose-dependency, hazard functions, calculation of safe dose, and correlation with simulated studies and animal experiments. Other considerations in the estimation of safe dosages of carcinogens are briefly mentioned and include the following: the difference between animal models and actual human environments, the complexity of carcinogenesis, and necessary features of in vitro and in vivo experiments. (25 refs)

- 79-6604 Can Mutation Theories of Carcinogenesis Set Priorities for Carcinogen Testing Programs? (Eng) Stich, H. F. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Center, Vancouver, British Columbia, Canada); Acton, A. B. *Can J Genet Cytol* 21(2): 155-177; 1979.

The use of mutation theories of carcinogenesis in setting priorities for carcinogen testing programs is reviewed. A model of carcinogenesis is proposed as a basis for this discussion. Carcinogenesis is envisaged as the loss of regulatory function due to mutations or deletion of specific regulator (*R*) genes followed by

derepression and increased activity of tumor (*Tu*) genes. Mutations are assumed to be the main cause of impairment of *R* gene activity. According to the mutation model, a carcinogen must initiate the process of carcinogenesis by inducing a mutation and must also be present after the original clones are formed to induce gene mutations or chromosome aberrations, thus bringing about an inactivation of remaining *R* genes. Short-term tests that rely on only one endpoint (mutations, chromosome breakage, DNA fragmentation, inhibition of DNA replication) are limited in their scope because they reveal only one facet of carcinogenesis. These tests must be complemented by tests that include other endpoints that are actually a part of neoplastic transformation. Tests for DNA fragmentation, DNA repair, micronuclei, etc, could be adapted for use in human biopsy, surgical, or autopsy specimens. The inclusion of such tests would reveal the organ-specific actions of carcinogens. The design of in vitro test systems capable of detecting and quantitating promoter and anti-promoter actions of chemicals should be given a very high priority. (87 refs)

- 79-6605 The Importance of Frame-Shift Mutations in Carcinogenesis. (Eng) Presber, W. (Inst. Virology, Humboldt-Univ., Schumannstr. 20/21, 104 Berlin, E. Germany); Kruger, D. H. *Fortschr Onkol* 4: 175-179; 1979.

A molecular mechanism of carcinogenesis which encompasses several hypotheses and reconciles certain contradictions is proposed. It is suggested that cancer results from a defect in the cell's molecular regulation and that realization of the cancer information can be explained by a frame-shift mutation. The hypothesis that carcinogenesis occurs as a result of frame-shift mutation is valid for both chemically and virally induced malignant transformation. If a virus were integrated into the host cell DNA without frame shift and it had no function that interfered with the host's gene expression, infection would proceed without transformation. Such silent proviruses could be induced by some chemicals, however, so that frame-shift mutations can be produced indirectly by agents that are not themselves frame-shift mutagens. Based on the proposed model, radiation would act as a carcinogen by causing primary DNA lesions, which would in turn induce repair processes. During repair, frame-shift mutations could occur, and the repair processes could lead to a high frequency of virus integration and thereby cause frame shifts. (34 refs)

- 79-6606 A Theory of Cancer Induction by Parametric Excitation. (Eng) Barrett, T. W. (Dept. Physiology and Biophysics, Univ. Tennessee Center Health Sciences, 800 Madison Ave., Memphis, TN 38163). *Cancer Biochem Biophys* 3(4): 189-192; 1979.

A theory of cancer induction by ultimate carcinogens via parametric excitation is presented. The requirement for energy transfer in the perturbation of DNA is discussed, and the concept of energy transfer by resonance is rejected in favor of energy transfer by parametric excitation, of which resonance is a special case. A remarkable agreement between the Raman vibrational bands of ultimate carcinogens, various hypochromic bands of DNA, and the predictions of parametric excitation theory was observed. The results suggest that the peculiar relation of an ultimate carcinogen and DNA results in a parametrically induced transfer in the vibrational mode. The problem of cancer induction then becomes one of analytical mechanics. This theory offers little hope for the development of a method that would completely prevent cancer induction, but it does offer the possibility of develop-

ing an extremely quick and efficient test of environmental molecules for ultimate carcinogenicity. If a molecule has Raman bands that may parametrically excite a DNA hypochromic band, then that molecule may be assumed to be a carcinogen requiring no metabolic activation for its effect. (30 refs)

- 79-6607 Teratogenic and Carcinogenic Effects of Some Chemicals During Prenatal Life in Rats, Syrian Golden Hamsters, and Minipigs. (Eng) Ivankovic, S. (German Cancer Res. Center, Heidelberg, W. Germany). *Natl Cancer Inst Monogr* (51): 103-115; 1979.

Studies on the teratogenicity and carcinogenicity of alkylnitrosoureas are reviewed. When pregnant rats were treated with ethylurea and sodium nitrite in the second half of gestation, all the offspring died from neurogenic tumors. The median teratogenic dose of ethylnitrosourea (ENU) was 46 mg/kg and corresponded to about one-fifth of the LD₅₀. Teratogenesis was strictly dose-dependent in the Syrian golden hamster and minipig as well as the rat. ENU is also a potent carcinogen in these species, and in mice, when administered prenatally. When administered to rats on day 12 of gestation or later, ENU invariably induced malignant nervous system tumors and, occasionally tumors in the progeny. Tumors with the shortest induction time (190 days) were located in the nervus trigeminus and the ganglion Gasserii. All were rapidly growing neurosarcomas. Malignant tumors of the peripheral nerves were more frequent than those of the brain. The median latency of the peripheral nerve tumors was 215 days; that of the brain tumors was 250 days. Most brain tumors were mixed gliomas. Methylnitrosourea and n-butylnitrosourea were much less active when tested for carcinogenicity, but n-propylnitrosourea was almost as effective as ENU. Simultaneous po administration of L-citrulline and sodium nitrite after day 12 of gestation induced nephroblastomas in 6/22 rat progeny. Fetal tissue was 50 times more sensitive than adult tissue to low doses of the carcinogens. (65 refs)

- 79-6608 Host Factors Affecting Perinatal Carcinogenesis by Resorptive Alkylnitrosoureas in Rats. (Eng) Koestner, A. (Dept. Veterinary Pathobiology, Ohio State Univ., Columbus, OH 43210); Swenberg, J. A.; Denlinger, R. H. *Natl Cancer Inst Monogr* (51): 211-217; 1979.

Studies of ethylnitrosourea (ENU)-induced perinatal carcinogenesis in rats, mice and hamsters are reviewed. Under optimal conditions, nearly 100% of offspring of rats given ENU inoculations during late gestation developed nervous system tumors. With decreasing doses, the tumor incidence decreases and the latency period increases. Neuroectodermal cells were the target site in rats, but only tumors of the peripheral nervous system were found in hamsters. In mice, the highest incidence of neurogenic tumors (32%) was reported in the C3HeB/Fe strain; in other strains the incidence ranged from 0%-25%. The predominant tumor type also varied with strain. In a study of the transplacental passage of ENU, newborn syngeneic mice were inoculated with brain cell suspensions obtained 1, 4, or 24 hr after the transplacental exposure of CDF rats to ENU (50 mg/kg iv on gestation day 20). Mixed glial tumors developed 10-12 mo later at inoculation sites in 2/11 rats treated with the 1-hr collection and in 1/9 rats treated with the 4-hr collection. Thus, the molecular events of neoplastic transformation took place within 1 hr of ENU transformation. Dimethylnitrosamine (DMN) was effective as a transplacental carcinogen only during the last days of the pregnan-

cy. The neuro-oncogenicity of ENU in the rat increased with advancing pregnancy and culminated at parturition. In mice, however, the incidence of pulmonary tumors was highest when ENU was administered on gestation day 16. Although tumors were not induced by ENU in rat or mouse fetuses before the 12th day, embryotoxicity and teratogenicity were produced. The genetic concept of neoplastic transformation implicates change in the DNA molecule as the principal lesion in tumor induction. A second concept considers transformation to result from derepression of DNA sequences generally suppressed in the normal cell. Immunologic surveillance protects against bladder tumors but not neuroectodermal tumors in rats. However, tumor-specific transplantation immunity was found in syngeneic rats immunized and challenged with cells from a methylnitrosourea-induced brain tumor. (44 refs)

- 79-6609 Neoplastic Response of Mouse Tissues During Perinatal Age Periods and Its Significance in Chemical Carcinogenesis. (Eng) Vesselinovitch, S. D. (Dept. Radiology, Pritzker Sch. Medicine, Univ. Chicago, Chicago, IL 60637); Rao, K. V.; Mihailovich, N. *Natl Cancer Inst Monogr* (51): 239-250; 1979.

Studies of chemical carcinogenesis in perinatal mice are reviewed. (C57BL/6J x C3HeB/FeJ)F₁ mice were treated ip with ethylnitrosourea (ENU: 60 µg/g) prenatally (day 12-18 of gestation), neonatally (day 1), or at the age of 15, 18, or 42 days. The carcinogenicity of perinatal exposure to diethylnitrosamine, benzo(a)pyrene, aflatoxin B₁, DDT, dieldrin, and safrole was also studied. The most important modulator of carcinogenesis in the liver, lung, stomach, ovary, and lymphoreticular tissues was age at time of carcinogen exposure. Infancy was the most susceptible period. Depending on the carcinogen, the pattern of tumor development in different organs varied according to the enzymatic competence of tissues to activate and metabolize the agent. ENU, a spontaneously activated carcinogen, induced 59 types of primary tumors in 22 tissues. In contrast, exposure during infancy to procarcinogens requiring enzymatic activation led to tumors only at a limited number of sites. All carcinogens induced liver tumors. The character of the tumors depended on the carcinogenicity of the agent and the age at treatment. Perinatally induced primary liver tumors grew more aggressively and were more readily transplantable to isogenic hosts than tumors induced at later ages. Since susceptibility to carcinogens is greatest early in life, this perinatal bioassay may be a useful model for prescreening potential human carcinogens, especially when only small amounts of the test substance are available. (84 refs)

- 79-6610 The Significance of the Hamster Model in Carcinogenesis Testing. (Eng) Grandjean, C. J. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE 68105); Althoff, J. *Prog Exp Tumor Res* 24: 207-214; 1979.

Based on data from previous studies, the carcinogenicities of vinyl ethylnitrosamine (VEN) and diallylnitrosamine (DAN) for Syrian golden hamsters were compared with those for BD rats. VEN, a somewhat weak carcinogen in rats, was highly potent in hamsters in terms of toxicity, tumor latency and multiplicity, organs affected, and total dose required. In all instances, the hamster was more susceptible. DAN, which is noncarcinogenic in rats, produced a 100% tumor incidence in hamsters, affecting primarily the respiratory system. A significant number of tumors were induced by a single dose of DAN. A fundamental species dif-

ference appears to be responsible for the different biological responses to these two compounds. Of approx 100 N-nitrosamines which have been found to cause tumors in at least one species, some appeared devoid of or low in carcinogenic activity in rats only. (6 refs)

- 79-6611 Model Studies in Tobacco Carcinogenesis with the Syrian Golden Hamster. (Eng) Hoffmann, D. (Naylor Dana Inst. for Disease Prevention, American Health Foundation, Valhalla, NY 10595); Rivenon, A.; Hecht, S. S.; Hilfrich, J.; Kobayashi, N.; Wynder, E. L. *Prog Exp Tumor Res* 24: 370-390; 1979.

The use of the Syrian golden hamster (SGH) as a model for the study of tobacco carcinogenesis is reviewed. The SGH has a lower rate for spontaneous lung tumors than other rodents, and its respiratory tract more closely resembles that of man. Special smoking devices have been developed for the passive inhalation of cigarette smoke by hamsters. Since only a small portion of the carcinogenic smoke particulates reaches the trachea and bronchi, tumors are rarely seen in the lung, most histopathologic changes occurring in the larynx. These changes range from hyperplasia to papillomas and occasional carcinomas. In susceptible inbred lines of SGH, high incidences of laryngeal carcinoma occur. The smoke of experimental cigarettes which produces 'tar' with reduced carcinogenic activity in mouse skin also shows reduced tumorigenicity for the hamster larynx. During curing and smoking of tobacco, N'-nitrosornicotine is formed from nicotine and nornicotine; and N-nitrosodiethanolamine is formed from diethanolamine, a solubilization agent used to spray tobacco. Both nitrosamines induce papillomas in the trachea and carcinomas in the nasal cavity of the SGH. (42 refs)

- 79-6612 Carcinogenesis of N-Nitroso-Morpholine and Derivatives in Syrian Golden Hamster. (Eng) Mohr, U. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany). *Prog Exp Tumor Res* 24: 235-244; 1979.

Carcinogenicity studies of seven cyclic nitrosamines in Syrian golden hamsters are reviewed. Nitroso-acetidine, which is carcinogenic for rats and mice, produced no tumors when administered in the drinking water to hamsters. Inhalation of nitroso-pyrrolidine also produced no tumors in hamsters although an organotropic effect in the lungs was evident following sc administration. Nitroso-piperidine (NP) produced tracheal tumors, papillary polyps, and papillomas in hamsters. Tumor latency was increased by decreasing the frequency of administration, and decreases in dosage resulted in reduced tumor incidences and increased survival times. A single dose of 0.075 of the LD₅₀ induced tracheolaryngeal neoplasms in 20% of the hamsters treated. Administration of NP (100 mg/kg body wt, sc) to pregnant females resulted in a 0%-7% incidence of respiratory tract tumors in the offspring. Results obtained after sc nitroso-morpholine (NM) administration (80 mg/kg body wt/wk) were similar to those seen with NP, but with a higher incidence of nasal cavity tumors and some bronchogenic adenomas in the lungs. The tumor latency following a single dose of NM was shorter than that following a single dose of NP. Nitroso-2,6-dimethylmorpholine was less toxic than NP and considerably more toxic than NM. It produced respiratory tumors in 100% of the treated animals and also induced tumors of the upper digestive tract, liver, and pancreas after as little as 15 wk. The sites of tumor involvement varied with dif-

ferent routes of administration. The main target of sc nitroso-hexa-methyleneimine was the trachea, but tumors also developed in the nasal cavities and lungs. Oral nitroso-hepta-methyleneimine treatment resulted in a high incidence of upper digestive tract tumors and a significant number of upper respiratory tract tumors. (16 refs)

- 79-6613 The Case of Dapsone. News About Carcinogens: What's Fit to Print? (Eng) Bloom, B. R. (Dept. Microbiology, Albert Einstein Coll. Medicine, New York, NY). *Hastings Cent Rep* 9(4): 5-7; 1979.

Studies on the carcinogenicity of diamino-diphenylsulfone (dapsone), a drug used to treat leprosy and to prevent the emergence of chloroquine-resistant malaria, are reviewed in response to the release of a report by NCI that dapsone caused cancer in rats. In a standard animal carcinogenicity test, dapsone, given at the max tolerated dose, failed to cause an increased incidence of cancer in male or female mice, or in female rats, but did produce a significant increase in cancer incidence in male rats. A number of flaws in the design of the study weaken the validity of these results. However, another, better-designed study also showed a significant increase in the same kind of cancer, again only in male rats. It was concluded in this study that carcinogenesis was probably a secondary effect of fibrosis and tissue damage caused by dapsone. Dapsone and its known human metabolites and breakdown products failed to increase bacterial mutations in the Ames test. Three studies on patients treated with the drug for long periods because of leprosy have failed to show higher incidences of cancer compared with control groups. (3 refs)

- 79-6614 Toxicity of Spices Containing Methyleneedioxybenzene Derivatives: A Review. (Eng) Buchanan, R. L. (Dept. Nutrition and Food Sciences, Drexel Univ., Philadelphia, PA 19104). *J Food Saf* 1(4): 275-293; 1978.

The current data on the potential carcinogenicity of methylenedioxybenzene derivatives in spices are reviewed; and the properties of safrole, isosafrole, dihydroxysafrole, β -asarone, estragole, myristicin, elemicin, apiol, dillapiol, eugenol, piperine, capsaicin, and anethole are discussed. The identification of safrole (1-allyl-3,4-methylenedioxybenzene; found in black pepper, nutmeg, mace, star anise oil, cinnamon leaf oil, cocoa, and parsley), isosafrole, dihydroxysafrole (a metabolic derivative of safrole), β -asarone (used as a bitter flavor), and estragole (found in tarragon, fennel, basil, and turpentine) as weak carcinogens suggests that spices containing other methylenedioxybenzene derivatives or other closely related aromatic compounds should be investigated for carcinogenicity (particularly spices containing anethole, myristicin, apiol, dillapiol, piperine, eugenol, or methyl eugenol). (55 refs)

- 79-6615 Chronic Interstitial Nephritis as a Cause of Tumors of the Upper Urinary Tract. A Hypothesis. (Eng) Sorrentino, F. (Riviera di Chiaia, 207, I-80121 Naples, Italy); De Martino, A. M. *Urol Int* 34(6): 393-402; 1979.

Data supporting the hypothesis that chronic interstitial nephritis is the single common cause for the high incidence of upper urinary tract tumors in cases of phenacetin abuse, endemic nephropathy, or infected pyelic calculi are reviewed. For a carcinogen to be ef-

fective, it must be discharged in the urine in high concentrations and absorbed by the urothelium, remaining there for some time before excretion. It is hypothesized that interstitial nephritis, by slowing reabsorption through pyelo-lymphatic reflux and by impeding the lymphatic drainage of the pyelic and ureteral walls, leads to a prolonged intra-tissue stasis, thereby enhancing the effect of carcinogens. If this hypothesis is correct, a high incidence of upper urinary tract tumors should be observed in dialysis and renal transplant patients. (39 refs)

- 79-6616 Reactive Metabolites of Xenobiotics: Their Role in the Hepatotoxicity of Drugs. (Fre) Pessayre, D. (Unite de Recherches de Physiopathologie Hepatique (INSERM), Hopital Beaujon, 92118 Clichy, France); Benhamou, J. P. *C R Soc Biol (Paris)* 173(2): 458-468; 1979.

Studies of the metabolism and hepatotoxicity of drugs and the induction of microsomal enzymes are reviewed. Certain drugs are transformed into reactive metabolites by cytochrome P-450. The reactive metabolites bind covalently to hepatocytic macromolecules, thereby causing hepatic lesions. Induction of microsomal enzymes enhances the formation of reactive metabolites and increases the hepatotoxicity of these drugs. Compounds that form unstable reactive metabolites include chloroform, halothane, trichloroethylene, acetaminophen, phenacetin, cyclophosphamide, urethane, imipramine, iproniazide, natural estrogens, ethinylestradiol, norethynodrel, α -methyl dopa, and isoniazide. Isoniazide is first metabolized to acetylhydrazine, then to an unstable metabolite that binds irreversibly to hepatic proteins. (19 refs)

- 79-6617 Cell Culture as a Test System for In Vitro Detection of Carcinogenic Material. (Ger) Seemayer, N. (No affiliation given.). *Lufthyg Silikoseforsch* 11: 65-80; 1978.

The use of cultured cells for in vitro testing of chemicals for carcinogenesis is reviewed. The ability to produce malignancy in animals (usually *nu/nu* mice) is still the most valid evidence that transformation has occurred in culture. Golden Syrian hamster embryo cells were used as early successful models of carcinogenesis. These studies indicated that chemical carcinogenesis is a one-step process and that toxicity does not correlate with carcinogenesis. In a study of 120 compounds, correct identification of carcinogenicity in 90% of the tests was found only for the Ames test and the cell transformation test (CTC), although four other quick in vitro tests were evaluated. Fibroblasts from mouse prostates have been used to develop a test that is especially useful for testing polyaromatic compounds. The test requires at least 6 wk. A cocarcinogenic effect of particulate material from air has been shown with rat or hamster cells previously infected with an oncogenic virus. In vitro transformation of human cells by viruses and by chemicals has been reported. Current evidence from in vitro studies favors induction of transformation rather than selection of previously transformed cells as the mechanism of chemical carcinogenesis. (56 refs)

- 79-6618 Prenatal Exposure to Chemical Carcinogens and Its Effect on Subsequent Generations. (Eng) Tomatis, L. (International Agency Res. on Cancer, 150, cours Albert-Thomas, 69372 Lyon, Cedex 2, France). *Natl Cancer Inst Monogr* (51): 159-184; 1979.

Evidence that transplacental carcinogens can increase tumor incidence in untreated animals of the second and third generations is reviewed. In one experiment, 7,12-dimethylbenz[a]anthracene (DMBA: 350 or 500 μ g) was given ip to outbred Swiss mice a few days to 12 hr before delivery. Five females of the first generation (F_1) whose mothers had received 350 μ g DMBA were mated with their brothers to obtain the second generation (F_2). An increased incidence of tumors was observed in both the F_1 and the F_2 progeny. In the second generation tumor incidence was higher in females than males. The tumors involved mainly the mammary glands and ovaries in females, the paraurethral and lachrymal glands in males, and the lungs in both sexes. Similar studies with methylnitrosourea and ethylnitrosourea in rats showed that exposure to the carcinogens during pregnancy resulted in a high incidence of tumors in F_1 animals, and an increased incidence of tumors at specific sites in animals of the second and third generations. The administration of dichlorodiphenyltrichloroethane to CF-1 mice for five consecutive generations did not result in an increased incidence of tumors. It is suggested that the tumors observed in animals of the second and third generations occurred (1) as a consequence of a mutation at a specific locus or (2) as the result of interactions between environmental factors and an inherited lesion that did not produce cancer by itself. (98 refs)

79-6619 Incorporation of Transplacental Exposure into Routine Carcinogenicity Bioassays. (Eng) Swenberg, J. A. (Chemical Industry Inst. Toxicology, P. O. Box 12137, Research Triangle Park, NC 27709). *Natl Cancer Inst Monogr* (51): 265-268; 1979.

Theoretical and practical aspects of experimental transplacental and neonatal exposures to carcinogens are discussed and reviewed. Perinatal carcinogenesis has been demonstrated in humans and seven other species (mouse, rat, hamster, guinea pig, rabbit, pig, and opossum). Sensitivity of the fetus or neonate varies from 100x that of the adult to much less than that of the adult. Some compounds, like diethylstilbestrol, may only cause tumors transplacentally. A typical carcinogenesis protocol that incorporates transplacental and neonatal exposure utilizes 50-55 animals per sex per dose exposed to the test compound for 24 mo. Three dose-levels and controls are ordinarily used, with the highest dose being the max tolerated dose that does not reduce life-span or induce excessive wt loss. Exposure to the drug po usually begins on the 15th day of gestation in rats and mice; the time of first exposure is adjusted if other species are used. Chemicals that induce abortion, prevent delivery, or interfere with lactation cannot be tested by this protocol. Dosing of the pregnant female continues through parturition and weaning. For the latter part of the study, dosing of the neonate by gastric intubation is preferred. After weaning at 3-4 wk, the offspring are exposed by either mixing the compound with the food or water or by intubation. Usually, a minimum of 25 date-mated females are exposed per dose level, and 2 males and 2 females are selected from the litter to reduce inter-litter variation. Compounds to which pregnant women are likely to be exposed should receive priority for the combined transplacental-neonatal-conventional exposure type of bioassay. Short-term assays, many of which use in vivo-in vitro systems, may be utilized to determine such priorities. (6 refs)

79-6620 Perinatal Carcinogenesis: Biologic Curiosity or Practical Necessity? (Eng) Clayson, D. B. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd St. and Dewey Ave., Omaha, NE 68105). *Natl Cancer Inst Monogr* (51): 235-238; 1979.

The question of whether transplacental carcinogenesis should be included in rodent carcinogen bioassays is discussed. Perinatal carcinogenesis is not believed to differ fundamentally from carcinogenesis in the adult animal. Some differences, however, must be taken into account. Conversion of a precarcinogen to a reactive electrophile may occur in either the mother or fetus, and different tissues and processes may be involved in each case. The simplest test of fetal exposure would be to demonstrate the presence of the carcinogen or a metabolite in the fetus. Studies of carcinogen interactions with cellular macromolecules would be a more specific approach. More applicable results may be obtained from an examination of the metabolic capabilities of specific fetal tissues, the placenta, and the mother. The activities of metabolizing enzymes vary widely, and these variations should be considered. An additional possibility is that an ultimate carcinogen activated in maternal tissue may be too unstable to reach the fetus in concentrations sufficient to induce tumors. The time of pregnancy at which transplacental carcinogens are administered is also critical. Generally, these substances lead to embryotoxicity early in pregnancy, to teratogenicity later, and carcinogenesis late in pregnancy. Cell proliferation during development may enhance carcinogenicity. Known perinatal carcinogens such as diethylstilbestrol should be retested to determine their mechanism of action. Most classes of chemical carcinogens include perinatal carcinogens; ie, polycyclic aromatic hydrocarbons, aromatic amines and aminoazo compounds, nitrosamines, mycotoxins, hormones, and miscellaneous compounds like urethan. Among chemicals that should be tested transplacentally, drugs, including oral contraceptives and substances used in disease control programs, deserve the highest priority. Food additives are the second concern. General environmental contaminants have the lowest priority. Results of such studies may identify carcinogens not found in tests on adult animals. (29 refs)

79-6621 The Biologic Effectiveness of Ultraviolet Light. (Eng) Rupert, C. S. (Programs in Biology, Univ. Texas Dallas, P.O. Box 688, Richardson, TX 75080). *Natl Cancer Inst Monogr* (50): 85-89; 1978.

The biologic effects of visible and UV light result from photochemical changes in cell components. The amount of photochemical change induced in a small non-self-shadowing structure is proportional to the number of photons traversing it per unit area normal to the direction of propagation, summed over all component beam directions. Within an optically complex, absorbing, and scattering structure, this quantity is difficult to determine, but for skin it is approx proportional to the total number of photons per unit area entering its outer surface. The magnitude of some photobiologic effects depends on the total number of photons per unit area entering its outer surface. The magnitude of some photobiologic effects depends on the total amount of photochemical change induced, whereas others depend on the rate of photoproduct formation or on a more complex relation. The nature of the dependence must be determined before light measurements can be related to the magnitude. The effect of a polychromatic illumination depends on its wavelength distribution, weighted by the effectiveness of each wavelength (the action spectrum) under the conditions employed. Until the latter is known, no dosimetric characterization of the light is possible. The wavelength distribution can be determined by spectroradiometric measurement, with the weighting performed numerically, or (more conveniently, though less accurately) by the use of an analog reaction with an action spectrum like that of the photobiologic effect. (13 refs)

- 79-6622 Multiple Pathways of DNA Repair and Their Possible Roles in Mutagenesis. (Eng) Smith, K. C. (Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA 94305). *Natl Cancer Inst Monogr* (50): 107-114; 1978.

Current knowledge on the multiple pathways of the various types of DNA repair is reviewed, and, when possible, the pathways are classified as being either error-free or error-prone. In studies on bacteria, the excision repair of UV-radiation-induced DNA base damage has been divided into two major pathways on the basis of physiologic requirements and genetic control. The major pathway requires a functional *polA*⁺ gene, does not need complete growth medium, is largely error-free, and produces short patches during repair. The second pathway requires complete growth medium and functional *recA*⁺, *recB*⁺, *recC*⁺, *lexA*⁺, *uvrD*⁺, and *polC*⁺ genes; is mutagenic; and produces long patches during repair. A second type of excision repair exists, in which the modified base is removed by a DNA glycosylase, and the chain is nicked by an apurinic (apyrimidinic) acid endonuclease. Subsequent events are presumed to be similar to the above excision repair process. The postreplication repair system has been divided into at least four distinct pathways, three of which depend on functional *recB*⁺, *lexA*⁺, and *uvrD*⁺ genes, and are error-free. A fourth pathway depends on the above gene products but is blocked by postirradiation treatment with chloramphenicol, and may be the UV-inducible, error-prone, mutagenic pathway of repair ("SOS repair"). A possible fifth pathway is dependent on a functional *recF*⁺ gene and is independent of the *recB*⁺-dependent pathways. Mutagenesis is the result of error-prone DNA repair, and evidence is growing that carcinogenesis is also the result of error-prone repair. Therefore, a complete understanding of DNA repair is crucial to a complete understanding of the molecular basis of carcinogenesis. (72 refs)

- 79-6623 Mutagenesis and Cell Transformation by Ultraviolet Irradiation: Many Hypotheses for Few Results. (Eng) Radman, M. (Department Biologie Moleculaire, Universite Libre Bruxelles, B-1640 Rhode-Saint-Genese, Belgium); Spadari, S.; Villani, G. *Natl Cancer Inst Monogr* (50): 121-127; 1978.

UV light-induced mutagenesis in bacteria is a genetically controlled process that is dependent on the induction of some cellular functions, initially provoked by unrepaired photolesions in DNA. Experiments on the extent and fidelity of in vitro DNA synthesis on UV-irradiated templates by bacterial and mammalian DNA polymerases have attributed a crucial role in UV mutagenesis to the polymerase-associated 3' to 5' exonuclease activity. This implies that purified mammalian DNA polymerases α , β , and γ should be able to elongate DNA chains past pyrimidine dimers. A unified working hypothesis for mutational- and virus-induced cancer that involves two-stage carcinogenesis, ie, initiation by mutagens and the subsequent promotion by essentially non-carcinogenic promoters, is proposed. The model assumes the activation of an inducer protease. At effective mutagenic and carcinogenic doses, UV light damages nucleic acids almost exclusively, and the deficiency in a repair system that removes UV-induced pyrimidine dimers from the cellular DNA is accompanied by the mutation- and cancer-proneness to UV light. (52 refs)

- 79-6624 Interaction of Light and Chemicals in Carcinogenesis. (Eng) Davies, R. E. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Natl Cancer Inst Monogr* (50): 45-54; 1978.

The effects of interactions between chemicals and UV light on the carcinogenic process are examined in terms of the three-component system: chemical, light, and biologic target. Various two-component interactions, in addition to unique three-component interactions, are considered. Available information is incomplete concerning such possibilities as promotion by non-carcinogenic light, the contribution of acute or chronic phototoxic events to chemical or physical carcinogenesis, and the relationship between either photochemical carcinogenesis or chemically enhanced photocarcinogenesis and demonstrable phototoxic activity. Interactions such as optical absorption by, or photochemical alteration of, chemicals are considered primarily as confounding variables in experimental situations. It is argued that realities of human exposure may reduce the complexity of these problems in practical safety or regulatory considerations. (35 refs)

- 79-6625 Summary, Perspective, and Closing Remarks. (Eng) Urbach, F. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Natl Cancer Inst Monogr* (50): 199-201; 1978.

Papers presented at a recent international conference on UV carcinogenesis are reviewed. Epidemiologic evidence strongly indicates that sunlight and particularly UV radiation are important in the etiology of human skin cancer. UV wavelengths <320 nm comprise the primary carcinogenic stimulus. Varying the dose rate while keeping the total amount of radiation given per day constant resulted in major variations in carcinogenicity, as did altering the spectrum slightly in a polychromatic UV source. Thus, the assumption that the carcinogenic effects of various UV wavelengths are linearly additive is incorrect. Fractionating the UV dose while keeping the dose rate constant had little effect on carcinogenicity. The interaction of light and chemicals, the microscopic and ultrastructural features of UV-induced skin tumors, UV-induced oncogenic transformation in vitro, and the roles of the various pathways of DNA repair on mutagenesis and cell transformation were discussed. Mutagenesis may apparently result from error-prone DNA repair. Other topics of discussion included the production and measurement of UV light, the effects of heat, humidity, and wind on UV carcinogenesis, and immunologic parameters of UV carcinogenesis. Further evidence for the relationship between cumulative UV exposure and nonmelanoma skin cancer in white-skinned people was presented, and it was shown that malignant melanoma of the skin is related to UV exposure in a different way. In the etiology of malignant melanoma, other major causal effects appear to interact with the UV effects. (15 refs)

- 79-6626 Summary: Repair Processes and Their Role in Carcinogenesis. (Eng) Sutherland, B. M. (Dept. Biology, Brookhaven Natl. Lab., Upton, Long Island, NY 11973). *Natl Cancer Inst Monogr* (50): 151-157; 1978.

Two major aspects of DNA repair and its relationship to carcinogenesis were addressed: the identification of a premutagenic lesion in bacterial cells, whether such a lesion is in mammalian cells, and the relationship of such a lesion and carcinogenesis; and, second, having identified such a chemical alteration, the identification of biological and biochemical steps leading from chemistry to carcinogenesis. The limitations of extrapolation from prokaryote to eukaryote are emphasized. Evidence has been presented indicating that mutagenesis and probably carcinogenesis are due to errors in DNA repair. A general discussion is presented in which clarification of the above points is attempted. (no refs)

- 79-6627 **Ultraviolet Radiation and Skin Cancer in Mice and Men: Accumulation of Effect and Uncertainty of Prediction.** (Eng) Blum, H. F. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Natl Cancer Inst Monogr* (50): 11-12; 1978.

Studies performed 35 yr ago in mice exposed to repeated doses of UV radiation, as well as recent epidemiologic investigations and measurements of carcinogenic radiation in patients with nonmelanoma skin cancer, are reviewed. These studies showed that repeated doses accumulated. The effects of factors such as genetics, human behavior, skin type, and variation in intensity of sunlight cannot be evaluated quantitatively because of their uncertainty. The possibility of inherent indeterminacy must be kept in mind in the study of effects of sunlight. (2 refs)

- 79-6628 **Speculations on the Role of Ultraviolet Radiation in the Development of Malignant Melanoma.** (Eng) Kripke, M. L. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701). *J Natl Cancer Inst* 63(3): 541-548; 1979.

Evidence implicating UV radiation as an etiologic or contributing factor in malignant melanoma is reviewed. Analysis of skin cancer incidence by age and geographic location in the US suggests that both melanoma and nonmelanoma skin cancers are more prevalent in locations receiving high levels of UV exposure. However, melanoma, unlike other skin tumors, may not be related to the cumulative lifetime exposure to UV radiation. There is little doubt that melanoma of the lentigo maligna type is directly related to chronic exposure to sunlight. Some evidence from animal studies supports the existence of other associations between UV malignant melanoma: (1) UV could act as an initiator of malignant transformation that requires additional promotion for expression of the disease (there is no direct evidence to support this possibility, however); (2) UV light could function as a promoter; and (3) UV light may produce a systemic alteration conducive to tumor growth. Some human melanomas possibly occur without any participation of UV radiation, and most experimental melanomas fall into this category—some are genetically regulated, some chemically induced, and some spontaneous. Human melanomas might have in common only the cell affected in the neoplastic process. Additional division of human melanomas into subgroups based on biologic behavior, histologic features, and antigenic properties may permit the assignment of etiologic agents to particular categories of melanoma. - 79-6629 **Defective Repair of γ -Irradiated DNA in a Case of Xeroderma Pigmentosum.** (Eng) Mikhelson, V. M. (Acad. Sciences USSR, Inst. Cytology, Leningrad, USSR). *Fortschr Onkol* 4: 157-171; 1979.

The results of studies of DNA repair processes in mutants defective in different steps of repair are reviewed. Human mutations that lead to deficiencies in γ -damaged DNA repair include a form of xeroderma pigmentosum (XP), XP II, as well as progeria and ataxia telangiectasia. Diseases involving defects in DNA or chromosome repair fall into three categories: those with the nosological name XP; those united as "chromosomal breakage syndrome"; and those of premature senility. The clinical manifestations in a 22-yr-old Russian woman with XP II are discussed. Although she is the only XP patient described with a

defect in γ -injured DNA repair, other patients with increased sensitivity to ionizing radiation may also have had XP II. Following irradiation, the single-strand breaks in the DNA of the XP II lymphocytes from the above patient failed to rejoin. UV-induced unscheduled DNA synthesis was decreased in both XP and XP II lymphocytes, and XP II cells that were unable to rejoin γ -induced single-strand DNA breaks showed considerably reduced γ -induced unscheduled DNA synthesis. The data suggest that there is a DNA polymerase defect in XP II. The percentage of dicentric and rings in the chromosomes of γ -irradiated XP II cells was similar to that in XP cells and normal cells, and the chromosomes of XP II cells did not differ significantly from those of classic XP in UV-sensitivity. XP II lymphocytes did not differ from those of classic XP or normal cells in the rate of spontaneous chromosome aberrations. (77 refs)

- 79-6630 **Malignant Transformation In Vitro: Criteria, Biological Markers, and Application in Environmental Screening of Carcinogens.** (Eng) Borek, C. (Radiological Res. Lab., Dept. Radiology, Cancer Center, Columbia Univ., Coll. Physicians and Surgeons, 630 W. 168th St., New York, NY 10032). *Radiat Res* 79(2): 209-232; 1979.

Criteria for and biological markers associated with malignant transformation in vitro are reviewed, as is the application of environmental screening of carcinogens. Biological markers which distinguish malignantly transformed fibroblasts from their normal counterparts include pleomorphic morphology, lowered requirement for nutritional factors, loss of density inhibition of growth, complex topography as discernible by scanning electron microscopy, loss of surface proteins, incomplete glycosylation of membrane glycolipids and glycoproteins, increased production of specific proteases, decreased organization of the cytoskeleton, and acquisition of neoantigens. Several of these markers are not consistently found in transformed epithelial cells and therefore cannot serve to distinguish unequivocally neoplastic epithelial cells from their normal counterparts. The only criteria associated with transformation of both fibroblasts and epithelial cells are the ability of the cells to proliferate in semisolid medium and the ability to induce tumors in appropriate hosts. In vitro systems represent a powerful tool for screening the mutagenic/oncogenic potentials of physical, chemical, and environmental agents. Fibroblasts rather than epithelial cells are preferred for this purpose because of the clear-cut phenotypic differences between the normal and transformed cells. These systems have been useful in establishing that malignant transformation can be induced by as little as 1 rad of x-rays or 0.1 rad of neutrons, and that fractionation at low dose levels leads to enhanced transformation. They have also been useful in identifying a large number of hazardous chemicals and in evaluating the relationship between the mutagenic and carcinogenic potentials of radiation and chemicals. - 79-6631 **Is Cholecystectomy a Predisposing Factor in the Genesis of Colorectal Carcinoma?** (Ger) Peters, H. (Abteilung Chirurgie, Medizinische Fakultät der Technischen, Goethestrasse 27-29, 5100 Aachen, W. Germany); Keimes, A. M. *Dtsch Med Wochenschr* 104(45): 1581-1583; 1979.

Evidence that cholecystectomy increases the risk of colorectal carcinoma (CRCA) is reviewed. Among 779 patients with CRCA, 42 had undergone cholecystectomy previously (Group CX). The age at diagnosis of CRCA in Group CX was approx 10 yr younger than that of the patients who did not undergo cholecystectomy.

The distribution of tumor sites differed in Group CX, with a higher frequency in the transverse and ascending colon and a lower frequency close to the rectum. Group CX cancers were more likely to be undifferentiated. Reasons for the possible association of CRCA and cholecystectomy are discussed. A high intake of fat, cholesterol, and protein is associated with gallstone development and may also increase the risk of CRCA. One study showed a fall in B- and T-lymphocyte numbers and a decreased response to antigen after cholecystectomy. Removal of the gallbladder can cause changes in bile acid (BA) metabolism. After surgery, BA's enter the colon continuously instead of periodically (after eating). Deoxycholic acid, which is carcinogenic in mice, is the main BA after surgery but not in intact persons. 1,2-Dimethylhydrazine-induced colon cancer is more frequent in cholecystectomized mice than in intact mice. Gallbladder mucosa can reabsorb some BA metabolites as relatively inactive glycosides; a fraction of these are excreted in urine. These considerations may partly explain the increasing incidence of CRCA in West Germany. (22 refs)

- 79-6632 The Role of Inert Particles in Malignant Transformations: A Hypothesis of Carcinogenesis. (Eng) Ecanow, B. (Univ. Illinois Medical Center, 833 South Wood St., Chicago, IL 60680); Gold, B. H.; Kohn, D. B.; Ecanow, C. *Physiol Chem Phys* 11(2): 97-107; 1979.

The role of inert particles in malignant transformation is reviewed and a hypothesis of carcinogenesis is proposed. Controlled cellular growth exists in an aqueous matrix that undergoes a spectrum of reversible solvent and structural conformational changes. In contrast, malignant tumor formation occurs in an irreversible non-polar aqueous matrix (coacervate), meaning that in a physicochemical sense uncontrollable cell growth exists in a hydrocarbon-like milieu. It is proposed that foreign insoluble particles which locate on cellular surfaces can induce such coacervate structuring. Resultant formation of abnormal film matrices could initiate pathological transformations in the morphology, metabolism, and replication of the affected cells. This abnormal matrix formation may be a critical factor in the development of malignancies, in both the avascular and vascular stages. It would follow that drugs or other agents capable of disrupting coacervated water matrices could be effective in the treatment of cancer. (26 refs)

- 79-6633 Experimental Data Concerning the Question of the Synergic Action of the Influenza Virus and of Some Chemical Carcinogens in the Pathogenesis of Lung Cancer. (Eng) Sula, J. (2nd Dept. Medical Chemistry and Biochemistry, Charles Univ., 128 53 Prague, Czechoslovakia). *Neoplasma* 26(1): 17-22; 1979.

Information concerning the synergism of the influenza virus (IV) and some chemical carcinogens in the pathogenesis of lung cancer are reviewed. Various oncogenic and nononcogenic viruses have been shown to enhance the development, growth, and malignancy of hydrocarbon-induced tumors. In other experiments, the incidence of lung neoplasms was much higher in mice that received IV intranasally plus urethane ip than in those treated with either agent alone. A more marked proliferative response was observed in human embryonic lung cultures treated with both agents than in those treated with either agent alone, and cell transformation occurred in 48/55 cultures. In C57B mice exposed to three strains of IV (PR-S, B, and Sendai) plus carcinogenic hydrocarbon aerosols, cigarette smoke, or 3,4-benzpyrene, a progression from an initial

proliferative response through squamous metaplasia to squamous carcinoma was observed; no squamous carcinoma developed in controls treated with either virus or carcinogen alone. Lung tumors developed in 78.2% of XMR1 mice treated with IV A₂-Bethesda intranasally plus diethylnitrosamine (DEN) in the drinking water, 58% of mice treated with IV A-PR8 plus DEN, and 10% of mice given DEN only. The frequencies of gastric and hepatic carcinomas did not differ between animals treated with virus plus DEN and those given DEN alone. The mechanism of synergistic action between viruses and carcinogens may involve: (1) impairment of the host's immunologic response to the virus by the chemical or to the chemically induced tumor by the virus; (2) alteration of susceptibility to viral infection by the chemical or of the detoxification mechanism of the cell by the virus; (3) chemically induced viral activity or viral enhancement of cell permeability to the chemical; (4) joint action of virus and chemical upon the critical site in the host cell; (5) viral enhancement of mitotic activity; (6) chemical activation of latent viruses; and (7) viral induction of latent tumor cells. - 79-6634 Restriction Endonucleases, Simian Virus 40, and the New Genetics. (Eng) Nathans, D. (Dept. Microbiology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *Science* 206(4421): 903-909; 1979.

This paper is the text of the author's Nobel Prize lecture (1978). The use of simian virus 40 (SV40) DNA as a model eukaryotic chromosome for investigating the biochemistry of DNA replication, gene expression, and regulation of genes is discussed. Classical genetic techniques (random mutagenesis and selection of desired phenotypes) led to the isolation of mutants comprising only about 50% of the SV40 genome. The use of site-specific restriction endonucleases made it possible to induce mutations at preselected sites on the molecule and isolate individual mutants without the need for phenotype selection. The methods used to dissect the tiny SV40 genome are directly applicable to more complex DNA molecules that can be isolated in homogeneous form: large viral chromosomes, plasmids, DNA from cellular organelles, and even certain genes in mammalian DNA. The completely general application of restriction enzymes to the analysis of cellular chromosomes depends on recombinant techniques for cloning and amplifying individual DNA fragments from complex mixtures, and the ability to reintroduce active genes into living cells. With these techniques, chemical and functional analysis of the genome of every organism is possible. In time, it should be possible to elucidate the basic regulatory mechanisms used by plant and animal cells, and eventually to understand some of the complex genetic programs that govern the growth, development, and specialized functions of higher organisms. (78 refs)

- 79-6635 Type C Retroviruses as Vectors for Cloning Cellular Genes with Probable Transforming Function. (Eng) Stephenson, J. R. (Viral Genetics Section, Lab. Cellular and Molecular Biology, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Khan, A. S.; van de Ven, W. J.; Reynolds, F. H. *J Natl Cancer Inst* 63(5): 1111-1119; 1979.

The use of type-C retroviruses as vectors for cloning cellular genes and the application of recombinant viruses for isolating cellular genes, including those with transforming potential, and the subsequent insertion of DNA transcripts of such recombinant viral genes into bacterial plasmids are reviewed. Included in the discussion are the following: the biological properties and genomic struc-

ture of type-C retroviruses, recombinant type-C viruses with transforming potential, the expression of type-C helper virus proteins in nonproducer cells, high-mol-wt polypeptides encoded by replication-defective recombinant viruses containing type-C virus structural and nonstructural components, the purification of transforming virus-coded polypeptides from pseudotype virions, replication-defective mammalian recombinant viral genome structure, and the implications of type-C retroviruses as vectors for cloning eukaryotic cellular genes. The data presented establish that nucleic acid sequences of cellular origin can, by genetic recombination, be inserted into type-C retrovirus-genome RNA. Attempts to demonstrate an etiologic involvement of type-C retroviruses in human cancer have not been convincingly successful; however, such studies have generated considerable information regarding the molecular biology of these viruses. Type-C retroviruses now appear to be of greater significance as potential vectors in the cloning of cellular genes associated with tumor induction than as etiologic agents involved in the disease itself. (77 refs)

- 79-6636 **Mutagenesis and Embryonal Carcinogenesis.** (Eng) Knudson, A. G. (Inst. Cancer Res., 7700 Burholme Ave., Philadelphia, PA 19111). *Natl Cancer Inst Monogr* (51): 19-24; 1979.

Germinal mutation to a dominant gene accounts for an estimated 40% of retinoblastomas, 38% of Wilms' tumors, and 22% of neuroblastomas. The hereditary forms of childhood tumors are highly penetrant events in a tiny segment of the population. The nonhereditary forms are rare events ($\leq 1:10,000$ children) in the vast majority of the population. The hereditary tumors occur at an early age and are often multicentric; the nonhereditary tumors occur at a later mean age and are almost always solitary. There is little clinical difference between the two groups. It is postulated that somatic mutation may be involved in both hereditary and nonhereditary childhood tumors. In a model that fits the age-specific occurrence, it is hypothesized that all childhood cancers, whether hereditary or nonhereditary, are initiated by two mutations, one somatic and the other either germinal or somatic. The background incidence rates of these tumors would reflect spontaneous mutation rates in the germinal and somatic cells, which may be increased by mutagens. The gene for one tumor (retinoblastoma) seems to be located on chromosome 13. Clues to the physiopathology of these tumor genes come from consideration of their tissue specificity, their origin from embryonal cells, and their developmental effects. Childhood cancers may be manifestations of the homozygous states of a series of genes concerned with the differentiation of specific embryonal tissues. (26 refs)

- 79-6637 **Clinical Genetics and Pediatric Neoplasms: Pathogenetic and Etiologic Perspectives.** (Eng) Herrmann, J. (Dept. Pediatrics, Medical Coll. Wisconsin, 1700 W. Wisconsin Ave., Milwaukee, WI 53233); Elejalde, B. R. *Natl Cancer Inst Monogr* (51): 7-18; 1979.

The clinical and genetic aspects of childhood solid tumors and leukemias are discussed. Developmental principles and phenomena common to several tumors and tumor syndromes are critically evaluated. Certain tumors can be described in terms of "formal genesis" syndromes (including Wilms' tumor associated with aniridia, hemihypertrophy, or pseudohermaphroditism; DiGeorge syndrome with thymoma; Poland or Down's syndromes with leukemia; and retinoblastoma with secondary tumors);

"phakomatoses" (including tuberous sclerosis, neurofibromatosis, nevoid basal cell carcinoma syndrome, Gardner's syndrome, blue rubber bleb nevus syndrome, and other autosomal dominant disorders classified as tissue dysplasias) and hamartoma-dysplasia syndromes; solid childhood tumors frequently associated with congenital disorders (Wilms' tumor, neuroblastoma, or retinoblastoma); double and multiple primary tumors (including tumors in "cancer families"); and tumors related to immunologic defects and chromosomal abnormalities, whether constitutional or acquired. No single hypothesis on the cause and pathogenesis of cancer seems to apply to all disorders. It is concluded that multiple causes and pathways lead to the phenotype "cancer". In particular, the pathogenic relationship between tissue dysplasias and cancers should be investigated further. (100 refs)

- 79-6638 **Respiratory System Differences Relevant to Lung Carcinogenesis Between Syrian Hamsters and Other Species.** (Eng) Kennedy, A. R. (Harvard Sch. Public Health, Boston, MA 02115); Little, J. B. *Prog Exp Tumor Res* 24: 302-314; 1979.

Features of the hamster respiratory system relevant to carcinogenesis and anatomic differences affecting carcinogenesis among species (including hamsters, dogs, rats, and humans) are discussed. Histologically, the hamster trachea is similar to the human bronchus; it includes cartilage, glands, lymph nodes, nodules, and an epithelium containing goblet, ciliated, basal, intermediate, and brush cells, but rarely contains neurosecretory cells. Carcinogen-induced tumors of the hamster tracheobronchial epithelium are histologically similar to human bronchogenic carcinomas. Major differences existing in the nature of the mucous ciliary escalator among species may alter the incidence and location of the tumors. It is suggested that differences in respiratory system structure, distribution of lymphoid tissues and glands, patterns of mucus secretion, and types of epithelial cells may account for differences in susceptibility to carcinogenesis among species. (61 refs)

- 79-6639 **Mesothelioma and Exposure to Mixtures of Chrysotile and Amphibole Asbestos.** (Eng) Acheson, E. D. (Southampton General Hosp., Southampton, England); Gardner, M. J. *Arch Environ Health* 34(4): 240-242; 1979.

Data indicating a possible synergistic interaction between chrysotile and amphiboles in the etiology of mesothelioma are reviewed. Mixtures of amphiboles and chrysotile have been found to occur much more commonly in the lungs of mesothelioma patients relative to controls than have either of the main types of fiber alone. Exposure to mixtures of amphiboles and chrysotile are associated with a relative risk of mesothelioma of 61, compared with a relative risk of 12 for amphiboles alone and 6 for chrysotile alone. The observed relative risk associated with exposure to fiber mixtures is closer to that expected based on a hypothesis of multiplicative interaction than on a simple additive effect hypothesis. Mixtures in which amphiboles are predominant may be associated with a higher relative risk of mesothelioma than those in which chrysotile is predominant. Mesothelioma is rarely a consequence of exposure to chrysotile or amosite alone, but occurs more frequently in persons exposed in or near crocidolite mines. Further work is needed to clarify these relationships. (16 refs)

- 79-6640 **Epidemiology of Oral and Pharyngeal Cancers in the United States: Review of Recent Literature.** (Eng)

Smith, E. M. (Dept. Epidemiology, SC-36, Sch. Public Health and Community Medicine, Univ. Washington, Seattle, WA 98195). *J Natl Cancer Inst* 63(5): 1189-1198; 1979.

Morbidity and mortality patterns, major etiologic factors, and social, demographic, cultural, or psychological variables related to oral cancer in the US are reviewed. Most oral neoplasms have been reported as squamous cell carcinomas. Lip tumors have the highest frequency and pharyngeal tumors the lowest frequency of localized neoplasms. The reverse is true for distant staging. No single site has been reported as having the highest incidence rate. Although lip cancer occurs with the greatest frequency, its incidence is high only among white males. Cancers of the tongue, floor of the mouth, and other mouth sites have the next highest frequency, but they show high incidence rates for all groups and are associated with poor survival. The major etiologic factors for oral cancer are tobacco and alcohol, and these effects are associated with age, sex, and religion, and ethnic backgrounds. Pharyngeal and gum-mouth sites are particularly vulnerable to alcohol, regardless of sex. In the synergistic relationship of tobacco and alcohol, the latter produces a slightly greater relative risk. Miscellaneous etiological factors include cirrhosis, syphilis, diabetes mellitus, dental conditions, and nutrition. Sociobehavioral factors associated with oral cancer include race, geographic location, religion as related to tobacco usage and alcohol consumption, and socioeconomic status. Sociobehavioral elements may alter risk, stage of disease at diagnosis, treatment, or survival from oral cancer. Further investigation is needed to determine the impact of these elements on the reduction of oral cancer incidence and mortality rates. (86 refs)

79-6641 Oral Cancer and Herpes Simplex Virus--A Review.
(Eng) Shillitoe, E. J. (Dept. Oral Medicine, Hosp. Dentistry Univ. California, San Francisco, CA 94143); Silverman, S. *Oral Surg* 48(3): 216-224; 1979.

Studies on an association between herpes simplex virus (HSV) and oral cancer are reviewed. In one study, eight patients who developed lip carcinoma at a site of previous frequent recurrent herpetic infection were described; however, these reports were anecdotal and have not been confirmed. Almost all investigators have found that women with cervical carcinoma have increased levels of HSV-2 antibody compared with matched control subjects. In one study, complement-fixing HSV-1 antibody levels in 24

oral cancer patients did not differ significantly from those in controls. In another experiment, virus was detected in only 1/31 cultures established from oral carcinoma specimens. Ultrastructural examination of 21 of these oral carcinomas failed to show virus particles. However, studies have shown that electron microscopy and tissue culture are inadequate methods for detecting DNA viruses. Antibody to an HSV-related antigen was demonstrated in 25/26 patients with oral cancer, compared with 3/51 normal subjects. This result was confirmed in a smaller series and also in patients with cervical cancer, but the tumor specificity of these reactions has not been properly established. Animal experiments have not yet demonstrated a direct carcinogenic effect of HSV in vivo, but a cocarcinogenic effect has been shown. There is fairly substantial evidence for an association between HSV-1 and oral carcinoma, but further studies with larger patient groups are needed to produce conclusive evidence. (62 refs)

79-6642 Welcome and Introduction: Evidence and Epidemiology of Ultraviolet-induced Cancers in Man.
(Eng) Urbach, F. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Natl Cancer Inst Monogr* (50): 5-10; 1978.

Evidence is reviewed that supports the hypothesis that human skin cancer is causally related to chronic solar UV radiation exposure. The world distribution of UV radiation particularly the UV-B spectrum (280-320 nanometers), is discussed. There is a striking inverse relationship between nonmelanoma skin cancer incidence and latitude (linearly related to UV-B dose). The distribution of head and neck cancers is highest in skin areas receiving the most erythemogenic UV-B radiation. Melanin pigmentation is inversely associated with skin cancer: individuals with significant melanin pigmentation rarely develop skin cancer. Other variables in solar carcinogenesis include the time and duration of UV exposure, number of exposures per yr, clothing habits, occupation, age, genetic background, and environmental factors (wind, visible light, temperature, humidity, etc). The relationship of the thickness of the stratospheric ozone layer to the amount of solar UV-B that can reach the earth has been established. For each 1% reduction in ozone, there is approx a 2% increase in solar erythema-effective UV-B. Interactions between UV radiation and the increasing number of photoactive chemical agents in the environment are of growing concern. Whether a phototoxic agent will be photocarcinogenic or not remains to be determined. (13 refs)

CHEMICAL CARCINOGENESIS

- 79-6643 Effect of Intestinal Bacteria on Incidence of Liver Tumors in Gnotobiotic C3H/He Male Mice. (Eng) Mizutani, T. (Animal Physiology Lab., Wakohsi Inst. Physical and Chemical Res., Saitama 351, Japan); Mitsuoaka, T. *J Natl Cancer Inst* 63(6): 1365-1370; 1979.

The effect of intestinal bacteria on the incidence of liver tumors (ILT) was studied in germ-free (GF) male C3H/He mice, some of which were exposed to one or more pure cultures of bacteria. GF mice were kept in vinyl isolators and checked regularly for bacteria and fungi. Gnotobiotic (GB) mice were obtained from GF mice that were allowed to lick an appropriate culture broth; the first generation male offspring of these mice were used as the GB mice for the study. GB mice were also kept in vinyl isolators. Conventionalized mice (CN) were obtained by placing GF mice in aluminum cages in an ordinary animal facility. All mice were fed a commercial diet that was irradiated (5 millirads). They were autopsied at 18 wk of age. Among 49 GF mice, 19 (39%) had liver tumors; the number of tumor nodules/mouse (NTN/M) was 0.5. In the CN group, 14/17 (82%) had tumors, and the NTN/M was 1.6. All GB groups had liver tumor incidences >60%, except for GB12, in which 6/13 mice had liver tumors. This group was exposed to *Escherichia coli*, *Streptococcus fecalis*, *Lactobacillus acidophilus*, *Clostridium perfringens*, and *Bacteroides fragilis*. GB12 was the only group exposed to *L. acidophilus*. Monocontamination of this mouse strain with *L. acidophilus* was not achieved. The highest incidences were 12/12 among mice exposed to *Bacteroides multacidus*, and 19/20 among mice exposed to *E. coli*, *S. fecalis*, and four strains of *C. paraputrificum*. The latter group had the highest NTN/M observed (2.9). The histopathology was similar among the GF, GB, and CN groups. The tumor nodules observed did not invade the surrounding liver, and no metastases were found. No other types of neoplasms were observed. Most intestinal bacteria tested appeared to promote liver tumorigenesis. Bacterial interactions may also influence tumor incidence. (24 refs)

- 79-6644 Skin Cancer and Arsenical Intoxication from Well Water. (Eng) Wagner, S. L. (Environmental Health Sciences Center, Oregon State Univ., Corvallis, OR 97331); Maliner, J. S.; Morton, W. E.; Braman, R. S. *Arch Dermatol* 115(10): 1205-1207; 1979.

The occurrence of recurrent multiple clusters of arsenical keratoses and skin carcinomas in a 41-yr-old patient who had suffered arsenical intoxication 12 yr earlier is reported. Arsenical intoxication followed the ingestion of well water containing an extremely low level of arsenic (1.2 ppm). During the period from 12 to 15 yr following this episode, 43 skin lesions were removed. These lesions were shown histologically to be of two types: in situ squamous cell carcinomas of the arsenical type and superficial multicentric basal cell carcinomas without vacuolization. Arsenic was present in low levels in skin biopsy specimens from the normal-appearing back skin and from an area of skin cancer. This case supports the hypothesis that arsenic can be a carcinogen. (27 refs)

- 79-6645 Distribution of Cadmium in Human Blood Cultured in Low Levels of CdCl₂: Accumulation of Cd in Lymphocytes and Preferential Binding to Metallothionein. (Eng) Hildebrand, C. E. (Cellular and Molecular Biology Group, Univ. California, Los Alamos, NM 87545); Cram, L. S. *Proc Soc Exp Biol Med* 161(4): 438-443; 1979.

Cadmium metabolism in normal adult human blood exposed in culture to Cd at levels comparable to those found in the blood of humans exposed occupationally to this element was studied. Exposure of blood cells to CdCl₂ in culture resulted in Cd uptake by the lymphocytes, which accumulated approx 800-fold more Cd than did RBCs on a per cell basis. During the 72-hr exposure period, there was no evidence of cell death, and the blood cells did not clump. In lymphocyte lysates, approx 4% of the total cellular Cd was associated with the nuclear fraction. In RBCs, Cd was bound to several macromolecular species, none of which corresponded to the specific, inducible, Cd-binding protein metallothionein. In contrast, most Cd in the lymphocytes was associated with a low-mol-wt macromolecule characteristic of Cd-thionein. Cd exposure may alter normal immunocompetence associated with lymphocytes. (30 refs)

- 79-6646 Chromosomal Aberrations in Bone-Marrow Cells of Mice Given a Normal or a Calcium-deficient Diet Supplemented with Various Heavy Metals. (Eng) Deknadt, G. (Dept. Radiobiology, Mammalian Genetics Lab., B-2400 Mol, Belgium); Gerber, G. B. *Mutat Res* 68(2): 163-168; 1979.

Male C57Bl mice kept on a normal or low-calcium diet (1.1% and 0.03% Ca, respectively) were exposed for 1 mo to zinc chloride (0.5% Zn), lead acetate (0.5% Pb), or cadmium chloride (0.06% Cd) or to a mixture of these salts at half the above concentrations. Given in a poor calcium diet, these concentrations represent an LD₅₀/30 days. After the mice were killed, bone-marrow cells were assayed for chromosomal aberrations; and serum calcium was determined. Chromosomal aberrations were detected in the mice maintained on a low-calcium diet and exposed to lead, zinc or a mixture of lead, zinc and cadmium. The possible mechanism for the synergistic action on genetic effects of the lack of calcium and intoxication by heavy metals is discussed. (41 refs)

- 79-6647 Calcium Cyanamide. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (163): 1-112; 1979.

The carcinogenicity of calcium cyanamide was tested in 6-wk-old F344 rats and B6C3F1 mice. In subchronic studies with rats, calcium cyanamide caused diffuse follicular hyperplasia of the thyroid, which was dose related over the range 600 to 4,000 ppm. Preneoplastic changes were induced by the high dose. In chronic studies, male rats were fed calcium cyanamide at 100 or 200 ppm and females at 100 or 400 ppm for 107 wk; male and female mice received 500 or 2,000 ppm of the test chemical. In these studies, no

neoplasms could be clearly associated with calcium cyanamide administration in the rats, although the incidence of adrenal medullary tumors appeared to be in excess in the experimental groups based on the histopathologic examination. In male mice, the incidence of hemangiosarcoma was dose-related; in direct comparisons, however, incidences in the individual experimental groups were not significantly higher than those in controls (controls 1/20, low-dose 2/50, high-dose 10/50). In female mice, the incidences of lymphomas and leukemias were dose-related; in a direct comparison, the incidence of these tumors in the group that received the high dose was significantly higher than that in controls (controls 1/20, low-dose 11/46, high-dose 18/50). The incidence of these tumors in a historical-control group was 67/324, suggesting that the incidence of these tumors in the matched-control group in this study may have been abnormally low. Thus, neither the incidence of hemangiosarcoma in male mice nor of lymphomas or leukemias in female mice can clearly be related to calcium cyanamide administration. (19 refs)

- 79-6648 Bioassay of Lead Dimethyldithiocarbamate for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (151): 98 pp.; 1979.

A bioassay of technical grade lead dimethyldithiocarbamate was conducted by administering the test chemical in feed to Fischer 344 rats and B6C3F1 mice, at 25 or 50 ppm for 104-105 wk. Fifty rats or mice of each sex were used, and groups of 20 animals served as matched controls. Mean body wts of treated male rats and female mice were slightly lower than those of matched controls. Survival rates in both rats and mice were not altered by treatment, and the incidence of tumors was the same in treated and control animals. It is concluded that, under the conditions of the assay, lead dimethyldithiocarbamate is not carcinogenic for either Fischer 344 rats or B6C3F1 mice of either sex. (16 refs)

- 79-6649 High Incidence of Rat Mammary Carcinoma by Oral Administration of Ethyl Methanesulphonate. (Eng) Ueo, H. (First Dept. Surgery, Kyushu Univ., Fukuoka 812, Japan); Takaki, R.; Yamagami, H.; Nakano, S.; Okeda, T.; Sakakibara, K. *Cancer Lett* 7(2/3): 79-84; 1979.

The carcinogenicity of ethyl methanesulphonate (EMS) was tested in 40 female Wistar King A rats given 10^{-3} M in the drinking water for 12 wk. The rats were observed an additional 20 wk for tumor induction. Tumors were first detected 16 wk after the start of the study (6/40 rats) and gradually increased in number until the 32nd wk, when all 34 survivors had multiple sc tumors of various sizes in the neck and in the axillar and inguinal areas corresponding to bilateral mammary glands. There were no tumors in a control group. Histologically, the tumors were moderately differentiated adenocarcinomas of the medullary type. Most carcinomas showed invasive growth into the muscle layer or dermis and marked intraductal spread. Neither regional lymph node involvement nor distant metastases were detected. These histological findings and the sites of the tumors strongly suggest their mammary duct origin. (3 refs)

- 79-6650 HLA-B18 Antigens and Protection from Pulmonary Fibrosis in Asbestos Workers. (Eng) Huuskonen, M.

S. (Dept. Occupational Medicine, Inst. Occupational Health, Helsinki, Finland); Tiilikainen, A.; Alanko, K. *Br J Dis Chest* 73(3): 253-259; 1979.

The prevalence of histocompatibility locus (HLA) antigens was determined in Finnish asbestos workers with and without radiographic pulmonary fibrosis and in blood donors who had not been exposed to asbestos dust. Thirty-three HLA antigens were identified in a two-stage lymphocytotoxicity test with freshly separated peripheral lymphocytes from 64 patients with asbestosis and from 37 matched control subjects. The antigen frequencies of these groups were compared with those of 900 blood donors. The prevalence of HLA-B18 was decreased in the asbestosis subjects compared with the other groups. In the 37 exposed control subjects, the prevalence of HLA-B27 and Cw2 was increased. Lung cancers were found in six asbestosis subjects, all cigarette smokers. There were no significant differences in the HLA antigens between these patients and other workers with asbestosis or the blood donors. No association was detected between any HLA antigen and the severity of asbestosis, or the progression of diffuse fibrosis. No HLA antigen was correlated with the rate at which pulmonary fibrosis developed during exposure to asbestos. However, the increase in HLA-B27, Cw2, and HLA-B18 in the asbestos-exposed controls suggests that these antigens may protect against the development of pulmonary diffuse fibrosis. (9 refs)

- 79-6651 Effect of Methylmercury Chloride on Transplacental Tumors Induced by Sodium Nitrite and Ethylurea in Rats. (Eng) Nixon, J. E. (Dept. Food Science and Technology, Oregon State Univ., Corvallis, OR 97331); Koller, L. D.; Exon, J. H. *J Natl Cancer Inst* 63(4): 1057-1063; 1979.

The effect of methylmercury chloride (MeHg; 10 ppm in diet from weaning through mating and pregnancy until delivery) on the induction of transplacental tumors by sodium nitrite (SN; 0.5-2.0 g/liter in drinking water or 25-50 mg/kg by gavage during pregnancy) plus ethylurea (EU; 0.159%-0.63% of the diet or 50-100 mg/kg by gavage during pregnancy) was studied in W rats. Compared with controls (SN-EU only), the survival times of the postweanling progeny of rats given MeHg plus the two highest doses of SN-EU were reduced by 49% and 43%, respectively. These animals also developed tumors after mean latency periods 45% and 28% shorter, respectively, than those of the controls. Rats from the dams given MeHg plus the highest dose of SN-EU showed a 67% incidence of neural tumors before the first such tumor appeared in controls. The minimum latency period for the induction of neural tumors was reduced by 5 wk in the group given MeHg. The incidence of cranial nerve schwannomas was higher in the progeny of rats given MeHg plus SN-EU than in the SN-EU controls, and ependymomas appeared only in the progeny of the MeHg-treated dams. MeHg did not appear to affect the incidence or latency of neural tumors in the progeny of rats given the lowest doses of SN-EU. (24 refs)

- 79-6652 Mutagenicity of Metal Cations in Cultured Cells from Chinese Hamster. (Eng) Miyaki, M. (Dept. Biochemistry, Tokyo Metropolitan Inst. Medical Science, 3-18, Honkomagone, Bunkyo-ku, Tokyo 113, Japan); Akamatsu, N.; Ono, T.; Koyama, H. *Mutat Res* 68(3): 259-263; 1979.

The mutagenicity of metal chlorides (BeCl_2 , MnCl_2 , CoCl_2 , and NiCl_2) on cultured V79 Chinese hamster cells at the hypoxanthine-guanine phosphoribosyl transferase (HGPRTase) locus was

evaluated using the technique of selection for resistance to 8-azaguanine (8-AG). The spontaneous mutant frequency of 8AG resistance was $5.8 \pm 0.8/10^6$ cells. Treatment with BeCl_2 (2-3 mM) or MnCl_2 (1-1.5 mM) increased the resistance 2- to 6-fold. Approx 75% of the 8AG-resistant colonies were sensitive to amethopterin and 86% of the resistant colonies showed less than 3% of the wild-type HGPRTase activity. The mutant frequency of cells treated with CoCl_2 (0.2 mM) and NiCl_2 (0.4-0.8 mM) was only moderately increased (1.2- to 2.7-fold) and detectable only at low rates of cell survival. (14 refs)

- 79-6653 Cylindrical Laminated Bodies in Nickel-Subsulphide-induced Rhabdomyosarcoma in Rabbits. (Eng) Hildebrand, H. F. (Institut de Recherches sur le Cancer de Lille, Unite 124 de l'INSERM, B.P. no 3567, F-59020 Lille Cedex, France); Biserte, G. *Eur J Cell Biol* 19(3): 276-280; 1979.

Rabbit rhabdomyosarcoma was induced by im implantation of a large quantity of very pure nickel subsulphide. Until the present time, the rabbit has been considered resistant to Ni_3S_2 tumorigenesis. The tumors were similar to those induced in rats under the same conditions. Four different cell types were observed: small polygonal cells, small elongated cells, giant cells, and mature myofibers. Electron microscopy revealed a complete disorientation of myofibrils in mature myoblasts. Giant cells appeared by pluripolar endomitosis and always contained myofibrillar structures, but M-lines and Z-lines were not present in these cells. Cylindrical laminated bodies were observed very often in all four cell types. They were formed of 4-nanomole fibrils arranged in crossed position in each lamella. Some of these paracrystalline structures were also observed in nuclei. The laminated bodies were considered to be abnormal formations of contractile proteins produced during tumoral myofibrillar differentiation. (24 refs)

- 79-6654 Fenthion. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (103): 1-104; 1979.

The carcinogenicity of the organophosphate pesticide fenthion (10 or 20 ppm in the diet for 103 wk) in F344 rats and B6C3F1 mice was studied. There was no evidence of appreciable toxicity in either species during the study, although the survival of male mice given 10 ppm fenthion was significantly reduced relative to that in control mice. The incidence of interstitial cell tumors of the testes was nonsignificantly increased in male rats relative to that in untreated control rats. No significant increase in tumor incidence occurred in fenthion-treated female rats or mice relative to untreated controls. Dose-related increases in the incidence of sarcomas, fibrosarcomas, and rhabdomyosarcomas of the integumentary system were observed in fenthion-treated male mice relative to untreated controls. Although the data did not meet the Bonferroni criterion of significance, it is concluded that these tumors were associated with the administration of the pesticide. The data indicate that under the conditions of this bioassay, fenthion is not carcinogenic in F344 rats or female B6C3F1 mice, but that it may be carcinogenic in B6C3F1 mice. (21 refs)

- 79-6655 Bioassay of Phosphamidon for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention,

NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (16): 98 pp.; 1979.

The carcinogenicity of technical grade phosphamidon (PA, 80 or 160 ppm, incorporated in the feed for 62-80 wk) was studied in Osborne-Mendel rats and B6C3F1 mice. Indications of PA toxicity were observed in both species, but sufficient numbers of animals lived long enough to be at risk for the development of late-appearing tumors. The incidence of hemangiomas and hemangiosarcomas of the spleen in the PA-treated male rats showed a significant increase with dose, but the incidence was not significantly higher than in matched controls or historical controls from the same laboratory. The incidence of C-cell adenomas and carcinomas of the thyroid was significantly increased in a dose-dependent fashion in the PA-treated female rats, but the incidence was not significantly higher than in historical controls from the same laboratory. Tumor incidence in the PA-treated mice was not significantly increased. It was concluded that under the conditions of this bioassay, PA is not carcinogenic for B6C3F1 mice. The data were insufficient to allow conclusions regarding the carcinogenicity of PA for Osborne-Mendel rats. (14 refs)

- 79-6656 Bioassay of Formulated Fenaminosulf for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Tech Rep Ser* (101): 50 pp.; 1979.

The carcinogenicity of the fungicide fenaminosulf [p-(dimethylamino)benzenediazosulfonic acid sodium salt] was tested in Fischer 344 rats and B6C3F1 mice divided into groups of 50 animals of each sex. Fenaminosulf was administered in the feed at concentrations of 0.10% and 0.05% for rats, 0.19% and 0.10% for male mice, and 0.10% and 10.05% for female mice. Control animals in corresponding numbers were fed a basal diet. After receiving the compound for 78 wk, the rats were observed for an additional 31 wk and the mice for an additional 19 wk. Tissue masses were determined by monthly observation and palpation. Necropsies were performed on all animals whether they died naturally or were sacrificed. Slides were prepared from 30 separate organs or tissues. There was a significant association between fenaminosulf dosage and mortality among mice. Rats did not show such an association. In neither species was there a significant association between chemical administration and the incidence of neoplasms. Endometrial stromal sarcomas were found in treated female rats, but their incidence was not significantly higher than that in control rats. An increased incidence of necrosis and mineralization of the renal papillary tubules occurred in treated animals of both species, compared with controls. It is concluded that under the conditions of this bioassay, dietary fenaminosulf was not carcinogenic in either rats or mice. (18 refs)

- 79-6657 Trauma, High-Molecular-Weight Dextran, and Tumor Growth. (Spa) Agostino, D. (Cancer Center/Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., New York, NY 10032); Agostino, N. *Sangre (Barc)* 24(5): 504-512; 1979.

The effects of high-mol-wt dextran (HMD, mean mol wt 1,000,000, 0.15 g/100 g in saline soln) on trauma induced by the im injection of turpentine (0.2 ml) into the right leg, and of the combination of HMD and trauma on the frequency of pulmonary metastases were studied in 400 female adult Wistar rats with

Walker's carcinosarcoma 256. Tumor cells were injected into the femoral vein 10 min after HMD and 48 hr after the injection of turpentine. The frequency of pulmonary metastases was 32% in the control group treated with tumor cells only, 48% in the group treated with HMD, 51% in the traumatized group, and 69% in the group treated with both HMD and turpentine. Both HMD and trauma caused a significant increase in the frequency of pulmonary metastases ($p < 0.001$). No definite explanation of the combined effect of trauma and HMD can be offered at present. (32 refs)

79-6658 Bioassay of Ethyl Tellurac for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (152): 112 pp.; 1979.

Ethyl tellurac was tested for possible carcinogenicity in F344 rats and B6C3F1 mice. Groups of 50 rats of each sex were fed a diet containing the test chemical at one of two doses (300 or 600 ppm for males, 150 or 300 ppm for females) for 105 wk; groups of 20 animals fed a normal diet were used as controls. Groups of 50 mice were fed a diet initially containing 2,500 or 5,000 ppm. Because of signs of toxicity, the doses were reduced to 500 and 2,000 ppm at wk 38 (females) or wk 41 (males); the reduced doses were maintained for 66 wk for the males and raised to 2,000 and 5,000 ppm after 3 wk for the females. Mean body wts of treated animals were lower than those of control animals throughout the assay. Mortality was unaffected by treatment. An increased incidence of mesotheliomas occurred in male rats; this increased incidence was dose-related but not statistically significant. Adenomas of the lacrimal gland of the eye were observed in treated mice of both sexes but not in untreated animals; the increased incidence was not statistically significant. It is concluded that, under the conditions of the assay, ethyl tellurac was not carcinogenic in F344 rats and B6C3F1 mice. (20 refs)

79-6659 Bioassay of Iodoform for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (110): 44 pp.; 1978.

The possible carcinogenicity of technical-grade iodoform (triiodomethane) was tested by administering it to Osborne-Mendel rats and B6C3F1 mice for 78 wk. Groups of 50 mice or rats of each sex received iodoform by gavage in one of two dosages (142 and 71 mg/kg/day for male rats, 55 and 27 mg/kg/day for female rats, 93 and 47 mg/kg/day for both male and female mice). The treatment period was followed by an observation period of 34 wk for rats and 13-14 wk for mice. Groups of 20 matched animals similarly gavaged with pure corn oil or only fed a normal diet were used as vehicle and untreated controls. A correlation between dose and mortality was observed in male rats and mice of both sexes. No statistically significant differences in tumor incidence between treated animals and their matched controls was observed. It is concluded that, under the conditions of the assay, iodoform is not carcinogenic for Osborne-Mendel rats or B6C3F1 mice of either sex. (23 refs)

79-6660 Bioassay of dl-Menthol for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH,

Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (98): 112 pp.; 1979.

The carcinogenicity of dl-menthol (3,750 or 7,500 ppm for rats and 2,000 or 4,000 ppm for mice, incorporated in the diet for 103 wk) for Fischer 344 rats and B6C3F1 mice was studied. Although a dose-related increase in mortality was observed in the menthol-treated female mice, survival at the end of the study was at least 62% in all groups. In neither of the species tested was tumor incidence in the menthol-treated animals significantly greater than that in the matched controls. Thus, under the conditions of this bioassay, dl-menthol was not carcinogenic for B6C3F1 mice or Fischer 344 rats. (28 refs)

79-6661 Induction of Chromosomal Aberrations in Peripheral Lymphocytes of Human Blood in Vitro, and of SCEs in Bone Marrow Cells of Mice in Vivo by Ethanol and Its Metabolite Acetaldehyde. (Eng) Obe, G. (Genetics Inst., Free Univ., Berlin, W. Germany); Natarajan, A. T.; Meyers, M.; den Hertog, A. *Mutat Res* 68(3): 291-294; 1979.

The chromosome breaking activity of acetaldehyde in cultured human lymphocytes from three healthy individuals and one patient with Fanconi's anemia and the effect of long term consumption of ethanol or treatment with acetaldehyde on the incidence of sister chromatid exchange (SCE) in mouse bone marrow cells were investigated. Acetaldehyde (0.001 or 0.002%, v/v) had no chromosome-breaking activity in lymphocytes from healthy individuals but induced a large number of chromatid-type aberrations in lymphocytes from the patient with Fanconi's anemia. Groups of 2-6 mice received either ethanol or tap water as their only liquid supply; then after 3, 5, 12, or 16 wk, they received a sc implantation of 55 mg 5-bromodeoxyuridine (BrdU) followed at 24 hr by an ip injection of colcemide. In another experiment, mice received ip injections (1 or 0.5 ml) of $10^{-4}\%$ (v/v) acetaldehyde soln followed by the BrdU and colcemide treatment. Routine preparations of bone marrow cell chromosomes were made and scored for SCE. A marked elevation of SCE was observed in the mice that drank only ethanol and in those injected with acetaldehyde. These data support the hypothesis that alcohol is carcinogenic in man. (13 refs)

79-6662 Mutagenic and Carcinogenic Effects of Vinyl Chloride. (Cze) Kucerova, M. (Katedra pediatrie, Institut pro dalsi vzdelavani lekaru a farmaceutu, Budejovicka 800, Prague 4, Czechoslovakia); Polivkova, Z.; Batora, J. *Prac Lek* 31(6/7): 249-252; 1979.

The mutagenicity of vinyl chloride (VC) was studied in peripheral blood lymphocytes of nine workers at a polyvinyl chloride manufacturing plant. The workers have been exposed to VC at concentrations of 15-150 ppm for 10-25 yr. Two of three cytogenetic examinations performed over a 2-yr period did not reveal any significant increase in the percentage of cells with chromosome aberrations compared with that in eight nonexposed controls; the final test, however, showed a significant increase in the percentage of cells with chromosome aberrations in three workers (5.2% vs 1.8% in the controls). The sister chromatid exchange (SCE) test was also performed at the time of the third test: it demonstrated significant increases in SCE frequency in 5/7 tested workers (13.8% vs 9.41% in the controls). (23 refs)

79-6663 Dermatological Aspects of so Called Vinyl Chloride Monomer Disease. (Eng) Czernielewski, A. (Dermatological Clinic, Medical Acad., Krzemieniecka 5, Lodz, Poland); Kiec-Swierczynska, M.; Gluszczyk, M.; Wozniak, L. *Derm Beruf Umwelt* 27(4): 108-112; 1979.

Dermatological findings in 30 workers (aged 26-54 yr) who had been in close and continuous contact with various phases of the vinyl chloride (VC) polymerization process for 2-11 yr are presented. The most common abnormalities were histopathologic changes (30 workers); history of symptoms of Raynaud's phenomenon (25 workers); positive results in digital plethysmography (24 workers) and in the vibro-tactile threshold sensory test (24 workers); and scleroderma-like skin lesions (23 workers). Acro-osteolysis was found in three patients and thrombocytopenia in one. Most abnormalities disappeared or showed signs of healing within 1-2 yr after exposure was discontinued. These results indicate the importance of dermatological examination in detecting the clinical pattern of VC-induced disease. (32 refs)

79-6664 Interaction of Potential Metabolites of the Carcinogen Ethylene Dibromide with Protein and DNA in Vitro. (Eng) Banerjee, S. (Lab. Organic Chemistry and Carcinogenesis, Inst. Environmental Medicine, New York Univ. Medical Center, New York, NY 10016); Van Duuren, B. L.; Kline, S. A. *Biochem Biophys Res Commun* 90(4): 1214-1220; 1979.

The covalent binding of ethylene dibromide (EDB), bromoacetaldehyde, and 2-bromoethanol to macromolecules was determined. [14 C]-bromoacetaldehyde and [14 C]-2-bromoethanol were synthesized from [14 C]-paraldehyde and [14 C]-ethylene oxide, respectively. EDB bound covalently to protein and DNA in a microsomal system prepared from male B6C3F1 mouse liver. Bromoacetaldehyde and 2-bromoethanol bound without enzymatic activation. Under these conditions, bromoacetaldehyde bound faster to macromolecules than did EDB or 2-bromoethanol. 2-Bromoethanol bound faster to DNA than did EDB but slower to protein. Both bromoacetaldehyde and 2-bromoethanol bound to protein and DNA to a greater extent than did EDB. These findings suggest that bromoacetaldehyde and 2-bromoethanol are important intermediates in EDB carcinogenesis. (16 refs)

79-6665 1,1-Dichloro-2,2-bis(p-ethylphenyl) ethane. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (156): 1-115; 1979.

The carcinogenicity of the pesticide 1,1-dichloro-2,2-bis(p-ethylphenyl)ethane (p,p'-E-DDD) was studied in F344 rats and B6C3F1 mice. The compound was incorporated in the diet for 105 wk, at 3,500 or 7,000 ppm in rats, 2,500 or 5,000 ppm in male mice, and 5,000 or 10,000 ppm in female mice. Subchronic feeding studies were conducted to determine the max tolerated doses of p,p'-E-DDD. Dose-dependent decreases in mean body wt were observed in experimental mice and rats, but mortality was unaffected by pesticide treatment. Tumor incidences in pesticide-treated rats and male mice were similar to control incidences in these species. Dose-related increases in the incidences of hepatocellular carcinomas and adenomas were observed in p,p'-E-DDD-treated female mice compared with controls. Although the increase was not statistically significant, it is suggested that these tumors may have been related to administration of the test chemical. Hepatocellular tumors were previously found

to occur following administration of p,p'-E-DDD and related compounds. It is concluded that under the conditions of this bioassay, p,p'-E-DDD is not carcinogenic for F344 rats or for male B6C3F1 mice, but that it may be carcinogenic in female B6C3F1 mice. (25 refs)

79-6666 Carcinogenicity of Halogenated Olefinic and Aliphatic Hydrocarbons in Mice. (Eng) Van Duuren, B. L. (Lab. Organic Chemistry and Carcinogenesis, Inst. Environmental Medicine, New York Univ. Medical Center, 550 First Ave., New York, NY 10016); Goldschmidt, B. M.; Loewengart, G.; Smith, A. C.; Melchionne, S.; Seidman, I.; Roth, D. *J Natl Cancer Inst* 63(6): 1433-1439; 1979.

Fifteen halogenated hydrocarbons of industrial and environmental importance were tested for carcinogenicity following chronic administration to Ha:1CR Swiss mice. Allyl chloride, 1,2-dibromo-3-chloropropane (DBCP), and vinylidene chloride initiated skin tumors when phorbol myristate acetate was used as a promoter. 1,2-Dibromoethane (DCE) was the only compound that significantly increased the incidence of skin papillomas, skin carcinomas, and lung tumors following repeated topical applications ($p < 0.05$). DCE, DBCP, and 1,1,2,2-tetrabromoethane induced lung and/or stomach tumors after repeated topical applications. cis-1,3-dichloro-propene and 2-chloropropanol induced sarcomas following sc administration, and stomach tumors developed following administration of 1-chloropropane by intragastric intubation. The following compounds showed no carcinogenic properties in this study: trichloroethylene, tetrachloroethylene, hexachlorobutadiene, chloroacetaldehyde, cis-1-chloropropene oxide, (trans-1-chloropropene oxide), and trichloroethylene oxide. (31 refs)

79-6667 Inhibition of Mammary Carcinogenesis of Dimethylbenzanthracene Treated Rats with a Brominated Triphenylethylene. (Eng) Rudali, G. (Equipe de Recherches 190 du C.N.R.S., Fondation Curie, 26, rue d'Ulm, 75231 Paris Cedex 05, France); Montes-Rendon, A.; Assa, R. *Biomedicine [Express]* 31(5): 142-146; 1979.

The effect of a brominated triphenylethylene (TBP, 2 or 20 ppm in the diet) on dimethylbenz(a)anthracene (DMBA, 20 mg po)-induced mammary carcinogenesis was studied using female Sprague-Dawley rats. All animals given DMBA alone developed tumors with a mean latency of 61 days. Rats given 2 ppm TBP plus DMBA had a 60% incidence of tumors after a mean latency of 82 days. In rats given 20 ppm TBP plus DMBA, the tumor incidence was 33-41% after a 4- to 5-mo latency period. The wt of the ovaries was greater in rats given DMBA only than in those given DMBA plus TBP, and TBP administration prevented the appearance of corpora lutea in the ovaries. The weights of the other glands were similar in rats given TBP plus DMBA or DMBA alone, and TBP did not prevent the necrosis of the adrenal cortex induced by DMBA. The mammary tumors were all adenocarcinomas, usually papillary with cysts and acini, except for one adenofibroma. The data suggest that TBP probably inhibits tumor development at an early stage. (20 refs)

79-6668 Induction of Unscheduled DNA Synthesis in Mouse Germ Cells Following 1,2-Dibromo-3-Chloropropane

(DBCP) Exposure. (Eng) Lee, I. P. (Lab. Environmental Toxicology, Natl. Inst. Environmental Health Sciences, P.O. Box 12233, Research Triangle Park, NC 27709); Suzuki, K. *Mutat Res* 68(2): 169-173; 1979.

Acute toxicity studies of 1,2-dibromo-3-chloropropane (DBCP) were carried out in CD-1 male mice, and the effect of DBCP on germ cell DNA was investigated. The toxicity studies demonstrated that the respective LD₅₀ values for prepubertal and adult mice were 180.7 mg/kg (154.0-197.5 mg/kg body wt) and 123 mg/kg (100.5-141.5 mg/kg body wt), which were significantly different. The slopes of the dose response curves (1.2) were steep and essentially the same, indicating a narrow margin of safety. In prepubertal male mice, a single maximally tolerated dose of DBCP (100 mg/kg, ip) induced significant unscheduled DNA synthesis in the premeiotic germ cells but not in spermatozoa. The authors speculate that dehydrobromination of DBCP molecules may result in a reactive aliphatic epoxide; which would then react with cellular macromolecules. Male sterility induced by chronic DBCP exposure may be attributed to saturation of germ cell DNA-repair capacity and thus, consequent manifestation of germinal aplasia in humans. (19 refs)

79-6669 Bioassay of Allyl Chloride for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (73): 53 pp.; 1979.

The carcinogenicity of technical grade allyl chloride (AC, 57 or 77 mg/kg/day for male rats, 55 or 73 mg/kg/day for female rats, 172 or 199 mg/kg/day for male mice, and 129 or 258 mg/kg/day for female mice, given by gavage 5 days/wk for 78 wk), a widely-used chemical intermediate, was studied in Osborne-Mendel rats and B6C3F1 mice. Survival of rats and male mice given the highest doses of AC was extremely poor, so that the number of animals surviving long enough to be at risk from late-developing tumors was not adequate for meaningful statistical analysis. The incidences of squamous cell carcinomas of the forestomach in AC-treated male and female mice and squamous cell papillomas of the forestomach in AC-treated female mice were higher than in historical controls from the same laboratory. Thus, 0.0, though no convincing evidence was obtained for the carcinogenicity of AC in Osborne-Mendel rats, the results suggest that this compound may be carcinogenic for B6C3F1 mice. (18 refs)

79-6670 Carcinogen-induced Chromosome Breakage in Chromosome Instability Syndromes. (Eng) Auerbach, A. D. (Lab. Genetics, Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Wolman, S. R. *Cancer Genet Cytogenet* 1(1): 21-28; 1979.

Cultured fibroblasts from patients with chromosome instability syndromes [Fanconi's anemia (FA), ataxia telangiectasia (AT), Bloom's syndrome (BS), xeroderma pigmentosum (XP)] and from normal individuals were examined for their susceptibility to diepoxybutane (DEB)-induced chromosome breakage. Clear differences in patterns of spontaneous and induced chromosome breakage in the different syndromes were found. In FA and AT, chronic exposure to a low concentration of the carcinogen induced extensive chromosome damage without reduction in cell viability. Exposure to the same concentration of carcinogen had no clastogenic effect on BS, XP, or normal fibroblasts. Furthermore,

when normal fibroblasts were exposed to a higher dose of the same chemical, there was a significant reduction in viability with little increase in chromosome aberrations. These experiments separate the clastogenic effect of DEB from its cytotoxic effect, and show genetic differences in susceptibility of cells to carcinogen-induced chromosome damage. (30 refs)

79-6671 On the Mutagenicity of Methadone Hydrochloride. Induced Dominant Lethal Mutation and Spermatocyte Chromosomal Aberrations in Treated Males. (Eng) Badr, F. M. (Dept. Zoology, Faculty Science, Univ. Kuwait, P.O.B. 5969, Kuwait); Rabouh, S. A.; Badr, R. S. *Mutat Res* 68(3): 235-249; 1979.

Inbred male C3H mice were treated ip with methadone hydrochloride (METH: 1-6 mg/kg/day x 3) before mating to virgin females for a total of 45 days. All METH doses increased the rate of preimplantation deaths in all postmeiotic stages. The higher doses (4-6 mg/kg) also affected spermatogonia. A quantitative dose-effect relationship could not be demonstrated, but the spectrum of changes increased with higher doses as more stages of spermatogenesis became more sensitive to METH. Mutation indices (based on total embryonic deaths) showed that METH affected spermatozoa, early and late spermatids, late spermatocytes, and spermatogonial stages. Chromosome analysis at diakinesis-metaphase I disclosed significant increases in the frequencies of sex chromosome and autosome univalents at all METH doses. A direct dose-effect relationship was observed. The most frequent multivalent type was chain quadrivalents. Translocation frequencies increased in a dose-dependent fashion at the lowest doses (0.1-0.2 translocations/cell at 1-4 mg/kg) but declined abruptly (0.05/cell) at the highest dose (6 mg/kg). It is concluded that METH may pose a genetic hazard to human populations. (43 refs)

79-6672 Rapid Induction of Epithelial Hyperplasia and Lymphoplasmacytosis in the Chinese Hamster (*Cricetus griseus*) by Mineral and Pristane Oil. (Eng) Yerganian, G. (Inst. Environmental Biomedical Sciences, Northeastern Univ., 360 Huntington Ave., Boston, MA 02115); Paika, I.; Gagnon, H. J.; Battaglino, A. *Prog Exp Tumor Res* 24: 424-434; 1979.

The development of pleomorphic lesions and latent tumors in response to mineral oil and pristane oil in pancreatic tissue and epithelial tissues of various organs in nondiabetic Chinese hamsters was studied. One hundred and twenty-one animals (both sexes, 288-452 days old) were randomly assigned to experimental groups (including 62 in the control group). Animals were sacrificed monthly following an initial ip injection of 0.5 ml of oil; tissues (heart, lung, liver, spleen, pancreas, kidney, adrenal) were fixed in Tellyesniczky's soln, embedded in paraffin, and sectioned at 5 µm before staining with hematoxylin and eosin. Approx 50% of the treated animals developed vasculitis and lymphoplasmacytosis, and 40% developed adrenal medullary hyperplasia (with predominance of males) and renal tubular hyperplasia. Intravascular and intraductal sarcomatoid occlusions prevailed by the 30th day after treatment; these appeared as prominent whorls of aggregated epithelioid cells within the vessels and ducts of the pancreatic mesothelium and lobules. Three of 17 males treated with pristane oil developed sarcomatous pancreatic tumors 32-79 days after treatment; these lesions were associated with extramedullary hematopoiesis and adrenal medullary hyperplasia. Two of 27 females developed tumors (1 hepatocarcinoma 167 days after treatment, 1 pleomorphic tumor associated with ex-

tramedullary hematopoiesis and regenerating liver 67 days after treatment with mineral oil). The heightened sensitivity of the Chinese hamster pancreas to the development of oil-induced lesions is believed to reflect the (auto)immune response portion of the genotype previously associated with diabetes mellitus. (22 refs)

79-6673 Morphology and Morphogenesis of Experimentally Induced Small Intestinal Tumors. (Eng) Hohn, P. (Pathologisches Institut der Universität, Postfach 3960, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Curr Top Pathol* 67: 69-144; 1979.

The morphology and morphogenesis of experimentally induced small intestinal tumors were studied. Intestinal tumors appeared in 250 rats 90-200 days after the administration of 1,2-dimethylhydrazine (200-300 mg/kg total, sc). The site of predilection was the upper small intestine, and the first detectable change was the appearance of circumscribed mucosal hyperplasias. Expansion of the proliferative compartment was associated with goblet cell atrophy and loss of differentiation capacity in enterocyte precursors. Adenomas and well-differentiated adenocarcinomas developed in these centers of proliferation, and poorly differentiated adenocarcinomas and solid carcinomas appeared to arise directly from transformed basal crypt epithelium. The tumors showed a largely endophytic growth, and they rapidly infiltrated the deeper layers of the intestinal wall. Numerous characteristic structures of the crypt epithelium were demonstrated in the tumor cells, and scanning electron microscopy showed that the differentiation of certain structures decreased with decreasing degrees of tumor maturation. A slight differentiation of the apical cell membranes of the tumor cells compared with the brush borders of normal enterocytes was associated with markedly diminished development of the glycocalyx. With the exception of alkaline phosphatase, enzymes located mainly in the endoplasmic reticulum and brush border of the enterocytes were no longer demonstrable in the tumor cells. It is concluded that the morphogenesis and morphology of these tumors are largely identical to those of human intestinal adenomas and carcinomas. (134 refs)

79-6674 Selective Protective Effect of Butylated Hydroxytoluene Against 1,2-Dimethylhydrazine Carcinogenesis in BALB/c Mice. (Eng) Clapp, N. K. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Bowles, N. D.; Satterfield, L. C.; Klima, W. C. *J Natl Cancer Inst* 63(4): 1081-1087; 1979.

The effect of the antioxidant butylated hydroxytoluene (BHT) on 1,2-dimethylhydrazine (DMH)-induced carcinogenesis was studied in male and female BALB/c mice. Survival was increased in male ($p < 0.001$) and female ($p = 0.011$) mice treated with BHT (0.75% of the diet beginning at 8 wk of age and continuing for life) plus DMH (20 mg/kg, sc, for 10 wk beginning at 11 wk of age) compared with those given DMH alone. The development of adenomas and adenocarcinomas in the descending colon and rectum was decreased significantly ($p = 0.0036$) in males and non-significantly in females given BHT plus DMH compared with those given DMH alone. The number of tumors per tumor-bearing mouse was also reduced by BHT treatment in both sexes. Colon and rectal tumors did not develop in BHT-treated or -untreated controls given no DMH. DMH alone induced lung tumors, while BHT alone did not; DMH plus BHT induced fewer lung tumors than DMH alone. The sex-specific protective effect of BHT on the

survival of mice treated with DMH and on the development of large bowel tumors (males only) resembled the sex-specific effect of BHT on diethylnitrosamine-induced squamous cell tumors in the female forestomach, but the mechanisms remain unknown. (31 refs)

79-6675 Promotional Effect of Sodium Barbiturate on Intestinal Tumors Induced in Rats by Dimethylhydrazine. (Eng) Pollard, M. (Lobund Lab., Univ. Notre Dame, Notre Dame, IN 46556); Luckert, P. H. *J Natl Cancer Inst* 63(4): 1089-1092; 1979.

Noninbred Sprague-Dawley rats received 1,2-dimethylhydrazine hydrochloride (DMH) by gavage or methylazoxymethanol acetate sc. Thereafter, one group received water to which 0.1% sodium barbiturate was added, and the other was given drug-free water. They were examined 20 wk after the beginning of the experiments. A direct relationship was noted between DMH dose and numbers of intestinal tumors induced in the rats. Rats given sodium barbiturate developed more intestinal tumors than did controls. (26 refs)

79-6676 Bioassay of (2-chloroethyl)trimethylammonium chloride (CCC) for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (158): 104 pp.; 1979.

(2-Chloroethyl)trimethylammonium chloride was tested for possible carcinogenicity in F344 rats and B6C3F1 mice. Groups of 50 rats or mice of each sex were fed a diet containing the test chemical in either of two concentrations (1,500 or 3,000 ppm for rats; 500 or 2,000 ppm for mice) for 108 wk (rats) or 102 wk (mice). Groups of 20 matched controls fed a normal diet were used. Mean body wt of treated animals was lower than that of controls (except in male mice). No toxic signs or dose-related mortality were observed. No significant increase in tumor incidence was observed in treated animals. It is concluded that, (2-chloroethyl)trimethylammonium chloride is not carcinogenic for F344 rats or B6C3F1 mice of either sex, under the conditions of the assay. (17 refs)

79-6677 Results of a Two-Year Chronic Toxicity and Oncogenic Study of Rats Ingesting Diets Containing 2,4,5-Trichlorophenoxyacetic Acid (2,4,5-T). (Eng) Kociba, R. J. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical USA, Bldg. 1803, Midland, MI 48640); Keyes, D. G.; Lisowe, R. W.; Kalnins, R. P.; Dittenber, D. D.; Wade, C. E.; Gorzinski, S. J.; Mahle, N. H.; Schwetz, B. A. *Food Cosmet Toxicol* 17(3): 205-221; 1979.

Groups of Sprague-Dawley rats (50 males and 50 females) were maintained on diets supplying 3, 10 or 30 mg 2,4,5-trichlorophenoxyacetic acid (2,4,5-T)/kg body wt/day for up to 2 yr, with an interim autopsy (on an additional 10 males and 10 females per group) after 118-119 days. The highest dose level was associated with some degree of toxicity, including a decrease in body wt gain and increases in relative kidney wt, in the volume of urine excreted and in the urinary excretion of coproporphyrin and uroporphyrin, plus slight morphological changes in the kidney, liver and lungs. The kidney changes primarily involved the presence of mineralized deposits in the renal pelvis. Parameters not adversely affected by this dose level included death rate, food

consumption, the occurrence of palpable masses, hematological indices, the results of routine urine analyses, urinary excretion of creatinine and delta-aminolevulinic acid, serum-chemistry values, wt of organs other than the kidneys, tumor incidence and gross and microscopic morphology of organ systems other than those mentioned above. At the intermediate dose level only minimal effects were noted, primarily an increased incidence of mineralized deposits in the renal pelvis and, in the males and only during the early phase of the study, an increase in urinary excretion of coproporphyrin. At the low dose level there were no changes that were considered to be related to treatment throughout the 2-yr period. Thus, this study revealed no oncogenic response in rats, even when the duration of 2,4,5-T administration extended over most of their life span at a dosage high enough to induce toxicity. (13 refs)

- 79-6678 Effects of Exposure to Acetaldehyde in Syrian Hamsters Simultaneously Treated with Benzo(a)pyrene or Diethylnitrosamine. (Eng) Feron, V. J. (Central Inst. Nutrition and Food Res. TNO, Zeist, Netherlands). *Prog Exp Tumor Res* 24: 162-176; 1979.

The chronic effects of acetaldehyde (AA, 1,500 ppm, 7 hr/day, 5 days/wk for 52 wk, administered as a vapor) and its possible significance as a cofactor in respiratory carcinogenesis induced by intratracheal benzo(a)pyrene (BP) or diethylnitrosamine (DENA) were studied using male Syrian golden hamsters. Exposure to AA vapor resulted in epithelial hyper- and metaplasia accompanied by inflammation of the nasal cavity and trachea. Extensive peribronchiolar adenomatoid lesions often accompanied by inflammatory changes occurred in the lungs after intratracheal instillations of AA (0.2 ml of a 4% soln given weekly). There was no evidence of a carcinogenic effect. Polyps, papillomas, squamous cell carcinomas, squamous adenocarcinomas, adenocarcinomas, fibrosarcomas, and/or anaplastic carcinomas were found in the larynx, trachea, bronchi, bronchioli, and alveoli of hamsters given varying doses of BP or DENA with or without AA. AA did not appear to act as a definite cofactor in respiratory tract carcinogenesis in this study. (14 refs)

- 79-6679 Synergistic Effect of Diethylstilbestrol on the Mutagenicity of 2-Acetylaminofluorene and N-Hydroxy-Acetylaminofluorene in the *Salmonella* Assay System. (Eng) Allaben, W. T. (Dept. Health, Education and Welfare, Food and Drug Admin., Natl. Center for Toxicological Res., Jefferson, AR 72079); Louie, S. C.; Lazear, E. J. *Cancer Lett* 7(2/3): 109-114; 1979.

Salmonella typhimurium, strain TA-1538, was used to study the mutagenic potentials of N-2-acetylaminofluorene (2-AAF, 2 and 4 μ g), N-hydroxy-N-2-acetylaminofluorene (N-OH-2-AAF, 1 and 3 μ g), and diethylstilbestrol (DES, 10 and 100 μ g) individually and in combination. In the presence of an induced or uninduced rat liver metabolizing system (S-9), the histidine-requiring strain of bacteria was reverted to prototrophy by 2-AAF and N-OH-2-AAF but not by DES. However, when DES was combined with 2-AAF or N-OH-2-AAF in the presence of the induced S-9 fraction, the number of revertant colonies was increased 2- to 4-fold above the levels obtained with the aromatic amines alone. The synergistic effect of the nonmutagenic DES on 2-AAF and N-OH-2-AAF mutagenicity was observed only when a 3-methylcholanthrene-induced rat liver S-9 fraction was used as the source of mammalian enzymes. When uninduced mouse or rat liver S-9 fractions were used in this test

system, an inhibitory rather than an enhancing effect was observed. (9 refs)

- 79-6680 Effect of pH on the Ratio of Substitution Products in DNA after Reaction with the Carcinogen N-Acetoxy-2-acetylaminofluorene. (Eng) Kriek, E. (Chemical Carcinogenesis Div., Antoni Van Leeuwenhoek-Huis, Netherlands Cancer Inst., Plesmanlaan 123, 1066 CX Amsterdam, Netherlands). *Cancer Lett* 7(2/3): 141-146; 1979.

The substitution reaction products of N-acetoxy-2-acetylaminofluorene (N-AcO-AAF) and the N-sulfate (potassium salt) of N-hydroxy-4-acetylaminobiphenyl (N-OSO₃K-AABP) with calf thymus DNA were determined after reaction in buffered soln of 0.10 M NaCl at pH values ranging from 4 to 9. With N-AcO-AAF, the ratio of N-(guanine-8-yl)-2-acetylaminofluorene to 3-(guanine-N²-yl)-2-acetylaminofluorene increased 2.2-fold over the entire pH range studied, starting at pH 9. With the N-OSO₃K-AABP, the total substitution of guanine was much lower (22-34 times) as compared with N-AcO-AAF; and the ratio of N-(guanine-8-yl)-4-acetylaminobiphenyl to 3-(guanine-N²-yl)-4-acetylaminobiphenyl was not affected by a change in pH of the reaction medium. As expected, heat-denatured DNA reacted more extensively with both esters, but an increase in substitution was much more pronounced for the biphenyl derivative (9 times) than for the fluorene compound (2.8 times). DNA degradation, denaturation, or interstrand cross-linking were not observed under the reaction conditions tested. (14 refs)

- 79-6681 Mutagenic Activation of N-Hydroxy-2-acetylaminofluorene by Developing Epithelial Cells of Rat Small Intestine and Effects of Antioxidants. (Eng) Schut, H. A. (Biochemical Pharmacology Section, Lab. Chemical Pharmacology, Div. Cancer Treatment, NCI, NIH, US Dept. Health, Education and Welfare, Bethesda, MD 20205); Thorgerirsson, S. S. *J Natl Cancer Inst* 63(6): 1405-1409; 1979.

The ability of subcellular fractions from male Sprague-Dawley rat small intestinal epithelial cells to activate N-hydroxy-2-acetylaminofluorene (AAF) to a mutagen for *Salmonella typhimurium* strain TA 1538 was studied. The mutagenicities of AAF samples activated by S9 fractions from villus tip and crypt cells and by cytosol were approx equal. Both the mutagenicity and N-hydroxy-2-acetylaminofluorene deacetylase activity with the S9 and cytosol fractions was inhibited by 10⁻⁵ M paraoxon; the inhibition was concentration dependent. The mutagenicity of the cytosol-activated AAF was increased by ascorbic acid, a max three- to fourfold increase being obtained with 10⁻³ M. Sodium selenite was toxic to the bacteria, especially in the absence of AAF. It was not mutagenic in the absence of AAF, but at 0.8 x 10⁻³ to 2 x 10⁻³ M, Na₂SeO₃ enhanced AAF mutagenicity. It is concluded that the mutagenic activation of AAF by subcellular fractions from villus tip and crypt cells was catalyzed by both a membrane-bound deacetylase(s) and soluble N-O-acyltransferase(s) and that these enzymes are expressed early in the differentiation of rat small intestinal epithelial cells. (41 refs)

- 79-6682 The Influence of 2-Acetylaminofluorene on the Dietary Induction of Pentose Phosphate Pathway Enzymes. (Ger) Fischer, W. (Pathologisches Institut,

Medizinischen Akademie Erfurt, Nordhauser Strasse 74, DDR-50 Erfurt, E. Germany); Grund, E. *Arch Geschwulstforsch* 49(5): 381-385; 1979.

The effect of feeding 2-acetyl-aminofluorene (AAF) on the induction of glucose-6-phosphate dehydrogenase (G-6-PDH) and 6-phosphogluconate dehydrogenase activities was studied in hooded rats (males, strain E, 180-220 g). AAF was mixed in the standard diet at 0.03%. Group 1 ate the AAF-diet for 2 wk, and group 2 for 4 wk. Group 3 received the AAF-diet for 4 wk, followed by standard diet for 2 wk. The animals were fasted for 3 days and then offered a diet containing 60% sucrose, 25% casein and 3% gelatin for 30 hr, after which they were killed. Liver G-6-PDH activity/g fresh wt after refeeding with the 60% sucrose diet increased 196-232%, 139%, 206%, and 188% above the fasting level in controls, group 1, group 2, and group 3, respectively. If the enzyme activities were expressed in units/g protein, enzyme induction in group 1 was only 75% of the induction achieved in controls; the amount of induction in groups 2 and 3 was similar to that of the corresponding controls. Little difference in induction of 6-phosphogluconate dehydrogenase was found for any of the AAF-fed groups. Metabolic effects of this type may be developed as quick tests for carcinogenicity. AAF inhibition of 6-phosphogluconate dehydrogenase activity induction has been observed previously. The lack of effect observed here may be due to the use of a different strain of rats. (6 refs)

- 79-6683 Induction of Foci of Altered Hepatocytes by a Single Injection of Azaserine to Rats. (Eng) Takahashi, S. (Dept. Pathology, Univ. Pittsburgh, Sch. Medicine, Pittsburgh, PA 15261); Katyal, S. L.; Lombardi, B.; Shinozuka, H. *Cancer Lett* 7(5): 265-272; 1979.

Experiments were carried out in male Wistar rats to determine whether foci of altered, γ -glutamyltranspeptidase (GGT)-positive hepatocytes could be elicited, under the promoting action of a choline-free diet, by a single ip injection of azaserine. After injection of azaserine (20 or 50 mg/kg), many foci developed in rats fed the choline-free diet containing acetylaminofluorene (AAF), but only a few occurred in rats fed a choline-supplemented (CS) diet containing AAF. Similar results were obtained in rats fed a plain choline-free diet or a plain CS diet and injected with a single dose of azaserine after partial hepatectomy. These findings indicate that azaserine is an effective initiator of liver carcinogenesis in rats, and that a CD diet acts as a strong promoter of the evolution of initiated liver cells to foci of altered, GGT-positive hepatocytes. (15 refs)

- 79-6684 Immunocytochemical Localization of Epoxide Hydrase in Hyperplastic Nodules Induced in Rat Liver by 2-Acetylaminofluorene. (Eng) Novikoff, A. B. (Dept. Pathology, Albert Einstein Coll. Medicine, Yeshiva Univ., 1300 Morris Park Ave., Bronx, NY 10461); Novikoff, P. M.; Stockert, R. J.; Becker, F. F.; Yam, A.; Poruchynsky, M. S.; Levin, W.; Thomas, P. E. *Proc Natl Acad Sci USA* 76(10): 5207-5211; 1979.

The localization of epoxide hydrase was examined in hyperplastic nodules induced in Sprague-Dawley rat liver by dietary 2-acetylaminofluorene. The nodules were separated from the livers; sections 15 μ m thick were prepared and exposed to medium containing Fab fragments of antibody specific to epoxide hydrase coupled to peroxidase. Thin sections were examined by electron microscopy. The nonparenchymal cells in the nodules were always

negative. Within the parenchymal cells, mitochondria and peroxisomes were always unreactive. Smooth endoplasmic reticulum (ER) and rough ER, including the nuclear envelope, were highly reactive. Thus, epoxide hydrase was visually demonstrated in the smooth and rough ER of hyperplastic liver nodules. However, the role, if any, of epoxide hydrase in the development of hepatocellular carcinoma remains unclear. (21 refs)

- 79-6685 Selenium Effects on the Carcinogenicity and Metabolism of 2-Acetylaminofluorene. (Eng) Marshall, M. V. (Biochemistry Dept., Univ. Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX 77030); Arnott, M. S.; Jacobs, M. M.; Griffin, A. C. *Cancer Lett* 7(6): 331-338; 1979.

Selenium (4 ppm in the drinking water) protected male albino rats fed diets containing 0.03% 2-acetylaminofluorene (AAF) against hepatic damage and also produced at least a 50% reduction in liver tumor incidence. In an in vitro assay system utilizing microsomes from Se-supplemented or nonsupplemented 3-methylcholanthrene (MC, 80 mg/kg)-induced rats, Se administration po affected AAF metabolism by leading to an increase in ring hydroxylation and a decrease in N-hydroxylation. Addition of Se to the microsomal assay system increased 3-OH-AAF formation and decreased N-OH-AAF formation, thus shifting the metabolic balance toward detoxification pathways. (11 refs)

- 79-6686 In Vivo Induction of Sister-Chromatid Exchanges in Liver and Marrow Cells by Drugs Requiring Metabolic Activation. (Eng) Schreck, R. R. (Div. Clinical Genetics, Mental Retardation Center, Children's Hosp. Medical Center, Boston, MA 02115); Paika, I. J.; Latt, S. A. *Mutat Res* 64(5): 315-328; 1979.

A highly sensitive method is presented for the detection of in vivo induction of sister-chromatid exchange (SCE) in mice subjected to partial hepatectomy. SCE induction by either acetylaminofluorene (AAF) or cyclophosphamide, both of which require metabolic activation, was significantly greater in both regenerating liver and bone-marrow cells of partially hepatectomized animals than in marrow cells of intact mice. These experiments confirm the ability of AAF, a well known mutagen-carcinogen, to induce SCE formation, even though the cytogenetic effects of this drug on nonhepatectomized mice is very small. The in vivo system described demonstrates the influence of the liver on drug-induced damage to extra-hepatic tissues. The procedures developed should facilitate the detection of drug-induced cytogenetic damage and permit the comparison of intertissue differences in SCE induction with tissue-specific differences in drug-activation pathways. (48 refs)

- 79-6687 Enhancing Effect of Inducers of Liver Microsomal Enzymes on Induction of Hyperplastic Liver Nodules by N-2-Fluorenylacetamide in Rats. (Eng) Tatematsu, M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya, Japan); Nakanishi, K.; Murasaki, G.; Miyata, Y.; Hirose, M.; Ito, N. *J Natl Cancer Inst* 63(6): 1411-1416; 1979.

The effects of inducers of liver microsomal enzymes on the induction of hyperplastic liver nodules by N-2-fluorenylacetamide

(FAA: 200 ppm in the diet for 2 wk) were studied in male F344 rats. The test compounds were given in the diet for 8 wk following FAA treatment, and partial hepatectomies were performed during the first wk after FAA treatment. Small foci were grossly visible on the livers of hepatectomized animals given FAA and polychlorinated biphenyls (PCB: 500 or 1,000 ppm), 3-methylcholanthrene (MCA: 70 ppm), phenobarbital (PB: 500 ppm), and/or β -naphthoflavone (NF: 500 ppm). The numbers of hyperplastic nodules in these animals and those given FAA plus 3-(3,5-dichlorophenyl)-5,5-dimethyl-oxazoline-dione-2,4 (DDOD) were significantly greater than those given FAA only. Animals given 1,000 ppm PCB plus FAA had more small nodules than those given FAA only and more than those given any of the other compounds plus FAA. Partial hepatectomy during PCB, PB, MCA, DDOD, and NF administration enhanced the induction of hyperplastic liver nodules by FAA. (37 refs)

79-6688 Persistence and Growth of Rat Liver Neoplastic Nodules Following Cessation of Carcinogen Exposure. (Eng) Hirota, N. (Naylor Dana Inst. Disease Prevention, American Health Foundation, 1 Dana Rd., Valhalla, NY 10595); Williams, G. M. *J Natl Cancer Inst* 63(5): 1257-1265; 1979.

The fate of neoplastic liver nodules following the cessation of exposure to N-2-fluorenylacetamide was studied in male F344 rats. Altered (hyperplastic) foci and neoplastic (hyperplastic) nodules identified by their resistance to iron accumulation were induced in the livers of rats by limited feeding of the carcinogen for three, four, or five cycles of 4-wk intervals separated by 1 wk of a basal diet. Foci were present by the end of three feeding cycles and increased in number with further carcinogen exposure. No nodules were present at the end of three or four cycles, but they appeared at later intervals after removal of the carcinogen. Nodules were present at the end of five cycles of feeding and increased in number later. Thus, nodules were found to be persistent and to have the progressive growth ability in situ that is characteristic of neoplasms. (49 refs)

79-6689 Opposite Effects of Lead on Chemical Carcinogenesis in Kidney and Liver of Rats. (Eng) Hinton, D. E. (Comparative and Environmental Pathobiology Program, Dept. Pathology, Univ. Maryland Sch. Medicine, Baltimore, MD 21201); Lipsky, M. M.; Heatfield, B. M.; Trump, B. F. *Bull Environ Contam Toxicol* 23(4/5): 464-469; 1979.

The effects of lead (incorporated in the diet as 1% lead acetate) and N-(4'-fluoro-4-biphenyl)acetamide (FBPA: 0.04% of the diet) on the development of renal adenocarcinomas (RA) and hepatocellular carcinomas (HCC) in male Fischer-344 rats were studied. The incidence of RA was higher in animals given both lead and FBPA (group 4) than in those given lead (group 3) or FBPA (group 2) alone or those given a control diet. The tumors produced by FBPA alone were histologically identical to those produced by lead plus FBPA. The RA were larger and the precancerous kidney lesions more numerous and faster growing in group 4 than in the other groups. Only a few formative lesions were observed in group 3 rats. Liver wt was increased in group 2 and, to a lesser extent, in group 4, but not in group 3, relative to that in controls. HCC developed several weeks earlier in group 2 than in group 4, which might suggest a possible retarding effect of lead. Lead also appeared to inhibit cytochrome P-450, whereas

FBPA induced it. The data indirectly suggest that the mixed-function oxidase system mediates FBPA carcinogenicity. (17 refs)

79-6690 Further Studies on the Carcinogenicity of a Food Additive, AF-2, in Hamsters. (Eng) Kinebuchi, M. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Kawachi, T.; Matsukura, N.; Sugimura, T. *Food Cosmet Toxicol* 17(4): 339-341; 1979.

The carcinogenicity of 2-(2-furyl)-3-(5-nitro-2-furyl)acrylamide (AF-2), once used as a food additive, was administered to golden hamsters of both sexes for 660 days at a level of 0.08 or 0.16% in the basal diet. The first forestomach tumors were detected on days 498 and 659 in the males and on days 444 and 451 in the females of the groups fed 0.08 and 0.16% AF-2, respectively. Respective incidences at day 660 in the two dosage groups were 65% and 100% in the males and 58% and 76% in the females. These tumors were squamous cell carcinomas of the forestomach in 15% and 47% of males and 0% and 6% of females given 0.08% and 0.16% AF-2, respectively. Esophageal tumors were found only in hamsters given 0.16% AF-2, the incidence being 35% in males and 6% in females. No tumors were found in other organs with the exception of one adrenal pheochromocytoma in a female given 0.08% AF-2. In the control groups, no tumors were observed in any organs examined. (15 refs)

79-6691 Differential Excision from DNA of the C-8 Deoxyguanosine Reaction Products of N-Hydroxy-2-aminofluorene and N-Acetoxy-N-acetyl-2-aminofluorene by Endonuclease S1 from *Aspergillus oryzae*. (Eng) Kriek, E. (Chemical Carcinogenesis Div., Antoni Van Leeuwenhoek-Huis, Netherlands Cancer Inst., Plesmanlaan 123, 1066 CX Amsterdam, Netherlands); Spelt, C. E. *Cancer Lett* 7(2/3): 147-154; 1979.

Calf thymus DNA was modified in vitro with either [G-³H]N-hydroxy-2-aminofluorene (AF) or [G-³H]N-acetoxy-N-acetyl-2-aminofluorene (AAF), and the nuclease S₁ digestion was studied under identical conditions. The ratios of the max reaction rate (V) and the Michaelis constant (K_m), V/K_m, indicate that AF-modified DNA was hydrolyzed three times more slowly than AAF-modified DNA under similar reaction conditions. The AF-modified DNA was slightly more susceptible to partial digestion by nuclease S₁ than unmodified control DNA. These results suggest that the local regions of denaturation induced by AF substitution are smaller than those associated with AAF modification. (13 refs)

79-6692 Mutagenic Activity of Gastric Juice. (Eng) Montes, G. (Sch. Medicine, Universidad del Valle, Cali, Colombia); Cuello, C.; Gordillo, G.; Pelon, W.; Johnson, W.; Correa, P. *Cancer Lett* 7(6): 307-312; 1979.

Gastric juice samples were taken from a rural Colombian Andes population at high risk for gastric cancer and tested for mutagenesis with *Salmonella typhimurium* strains TA100 and TA1538. Direct mutagenic effect was found in samples with detectable amounts of nitrite. However, up to 25 ppm nitrite alone did not result in detectable mutagenicity in this test system; thus the mutagenicity of the gastric juice samples (containing <9 ppm nitrite) could not be attributed to nitrite alone. Nitrite-negative

samples from the same area and samples from the low-risk area of Cali were negative using the same mutagenesis assay. (13 refs)

- 79-6693 Identification of Nitrohexane in Corn Treated with Nitrous Acid. (Eng) Hansen, T. J. (Dept. Medical Biophysics, Univ. Toronto, Toronto, Canada M4X 1K9); Archer, M. C.; Tannenbaum, S. R. *J Agric Food Chem* 27(5): 1072-1075; 1979.

Corn samples from Massachusetts and from a region of Colombia with a high incidence of stomach cancer were reacted with nitrite under acidic conditions. The major product formed was nitrohexane. Nitroalkanes represent a new class of compounds that may be present in certain foods or form in the stomach in the presence of nitrite. They give a positive thermal energy analysis response and may consequently interfere in the analysis of N-nitrosamine formation. Use of an auxiliary method such as UV photolysis would allow distinction between the two classes of compounds. (24 refs)

- 79-6694 Interaction of Wheat Bran with Nitrosamines and with Amines During Nitrosation. (Eng) Wishnok, J. S. (Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA 02139); Richardson, D. P. *J Agric Food Chem* 27(5): 1132-1134; 1979.

The extent of binding of a representative sample of nitrosamines to a standard bran was measured, and the effect of bran on the rate of formation of nitrosamines from amines and nitrite was determined. Nitrosamines were adsorbed by wheat bran, the extent of binding apparently being related to the structure of the nitrosamine. The rate of formation of N-nitrosodipropylamine was increased when the nitrosation of dipropylamine was carried out in the presence of bran. If the intestine is protected from exposure to nitrosamines by the binding of these compounds to fiber, then this protection may be less effective with the more potent carcinogens. (19 refs)

- 79-6695 Mutagenicity of Nitrosodiethanolamine on *Salmonella Typhimurium*. (Eng) Hesbert, A. (INRS, Avenue de Bourgogne, 54500 Vandoeuvre-les-Nancy, France); Lemonnier, M.; Cavelier, C. *Mutat Res* 68(3): 207-210; 1979.

The mutagenicity of nitrosodiethanolamine (NDEA) was examined in the Ames test using *Salmonella typhimurium* (TA100, TA98, TA1538, and TA1535) in the presence or absence of S9 mouse liver mix. NDEA exhibited mutagenic effects in TA100 and TA1535 in the absence of S9 mix at doses ranging from 1 to 10 μ l/plate; with or without the activation system, a linear relationship between dose and response was obtained. At higher doses, NDEA appeared to be mutagenic per se to TA100 and TA1535 and did not seem to require activation by enzymes to produce reactive electrophilic intermediates. These data indicate that further studies of the mutagenicity and carcinogenicity of NDEA (detected as a contaminant in synthetic cutting fluids) are needed. (13 refs)

- 79-6696 Detection of N-Nitrosodiethanolamine in Human Urine Following Application of a Contaminated Cosmetic. (Eng) Edwards, G. S. (New England Inst. Life Sciences, Waltham, MA 02154); Peng, M.; Fine, D. H. *Toxicol Lett* 4(3): 217-222; 1979.

High pressure liquid chromatography with nitrosamine detection was used to determine the presence of urinary N-nitrosodiethanolamine (NDEIA) following the application of an NDEIA-contaminated (77 ppm) cosmetic to the chest and back of a male subject. NDEIA was found in urine samples collected between 1 and 13 hr after application of the cosmetic. At least 17.3 μ liters of NDEIA were excreted in the urine during this period. Thus, NDEIA is absorbed from human skin to which a widely used facial cosmetic has been applied. (10 refs)

- 79-6697 The Influence of 5-Nitro-2-Furyl Acrylic Acid on Human Fibroblasts Cultivated In Vitro. (Eng) Slamenova, D. (Cancer Res. Inst. Slovak Acad. Sciences, 880 32 Bratislava, Czechoslovakia); Mazariova, O. *Neoplasma* 26(3): 267-274; 1979.

The effects of 5-nitro-2-furyl acrylic acid (NFA: 2-100 5mg/ml) on the synthesis of macromolecules by EUE human fibroblasts were studied in vitro. NFA in all concentrations had a cytostatic and/or cytotoxic effect on the cells, the reduction in cells being dependent on the NFA concentration. One of the first manifestations of the effect of NFA was stimulation of the incorporation of 14 C-thymidine (Tdr). Decreased Tdr incorporation was observed after prolonged NFA treatment or in the presence of high concentrations of NFA. In cells treated for 2 hr with NFA and then removed to control medium, a persistent cytostatic and/or cytotoxic effect was observed. DNA synthesis in such cells was inhibited in a dose-dependent fashion, and RNA synthesis and protein synthesis were inhibited by higher doses of NFA. The treated cells never showed recovery of DNA synthesis to control levels, even after treatment with the lowest concentration of NFA. (8 refs)

- 79-6698 Effects of Urethan, Dimethylnitrosamine, Paraquat, and Butylated Hydroxytoluene on the Activity of Lactic Acid Dehydrogenase and Isoenzyme Spectrum in the Mouse Lung. (Hun) Rady, P. (Kozegeszsegtani es Jarvanytani Intezet, Debreceni Orvostudományi Egyetem, Debrecen, Hungary); Arady, I.; Bojan, F. *Egeszsegtudomány* 23(3): 251-255; 1979.

The effects of urethan (1,000 mg/kg, ip), dimethylnitrosamine (DMNA: 10 mg/kg, ip), paraquat (20 mg/kg, ip), and butylated hydroxytoluene (BHT: 800 mg/kg, ip) on lung lactate dehydrogenase (LDH) activity was studied in LATI:CFLP male and female mice. Total lung LDH activity was increased significantly by the carcinogenic substances DMNA and urethan 7 days after treatment. LDH activity showed a further increase, almost reaching levels as high as those found in tumors induced within 35 days by these substances in preliminary experiments. Paraquat and BHT caused only a transient increase in LDH activity. The ratio of the H and M isoenzymes decreased steadily in the lungs of mice treated with urethan (0.782 on day 0, 0.627 on day 7, and 0.399 on day 35) and DMNA (0.787 on day 0, 0.658 on day 7, and 0.491 on day 35). The increase in LDH activity can be partly explained by the fact that chemically induced pulmonary adenomas of the mouse lung originate from type II pneumonocytes, which have an inherently higher LDH activity than do the other cells forming the alveolar tissue. Thus, the increased total LDH activity is due to the proliferation of type II pneumonocytes. (19 refs)

- 79-6699 Enhancement of Adenoma Formation in Mouse Lung by Butylated Hydroxytoluene. (Eng) Witschi, H.

(Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830); Lock, S. *Toxicol Appl Pharmacol* 50(3): 391-400; 1979.

Temporal relationships between urethan and butylated hydroxytoluene (BHT) in the enhancement of lung tumor formation were studied. Male Swiss-Webster mice (aged 6-8 wk) received a single dose of urethan (50, 100, 250, or 1,000 mg/kg, ip), which produces lung adenomata 14-24 wk after administration. Urethan-treated mice were injected with BHT (300 mg/kg, ip, 1x/wk x 13) starting 1 wk after urethan injection. The number of tumors per lung at 14 wk after urethan treatment was significantly increased by BHT at doses of 100-1,000 mg/kg and at 24 wk by doses of 250 and 1,000 mg/kg. Increased numbers of tumors per lung were also found when the interval between urethan injection and the first BHT treatment was extended up to 6 wk and when only four BHT injections were given. Pretreatment with 13 weekly BHT injections, followed 1 wk later by 1,000 mg/kg of urethan had no effect on the number of lung tumors. In 6- to 8-wk-old Balb/c mice, the simultaneous administration of urethan (500 mg/kg, ip) and BHT (400 mg/kg, ip) resulted in a decrease in the number of tumors per lung. In three mouse strains that are resistant to adenoma formation, treatment with BHT following urethan injection did not significantly increase tumor incidence or the av number of tumors per lung. These results suggest that BHT has several properties of a promoting agent for urethan-initiated adenoma formation. (30 refs)

79-6700 Concentration-dependent Mutation by Alkylating Agents in Human Lymphoblasts and *Salmonella typhimurium*: N-methyl-N-nitrosourethane and β -Propiolactone. (Eng) Penman, B. W. (Dept. Nutrition, Massachusetts Inst. Technology, Cambridge, MA 02139); Hoppe, H.; Thilly, W. G. *J Natl Cancer Inst* 63(4): 903-907; 1979.

The toxic and mutagenic effects of the alkylating agents N-methyl-N-nitrosourethane (MNUT) and β -propiolactone (BPL) were measured quantitatively in human lymphoblasts and *Salmonella typhimurium*. Forward mutation to 6-thioguanine resistance was measured in the human lymphoblasts, and forward mutation to 8-azaguanine resistance was measured in the bacterial cells after equigenerational (1.5 doubling times) exposures. In both systems, the induced mutant fraction rose linearly as a function of concentration for BPL and was biphasic for MNUT. The responses of the two assay systems to eight alkylating agents were compared. The exposure of the cells to each alkylating agent was calculated as exposure concentration multiplied by the time of exposure, and allowance was made for the decomposition of the alkylating agent during exposure (integral exposure). Human cells were 2.5-13 times more sensitive than was *S. typhimurium* to the alkylating agents methyl methanesulfonate, ethyl methane-sulfonate, propyl methane-sulfonate, N-methyl-N-nitro-N-nitrosoguanidine, methyl nitrosourea, and MNUT. *S. typhimurium* cells were 3 times more sensitive to butyl methane-sulfonate and 25 times more sensitive to BPL than were human cells. (17 refs)

79-6701 Carcinogenic Effect of N-Ethyl- and N-Amyl-N-Nitrosourethans on Female Donryu Rats. (Eng) Hirose, M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Maekawa, A.; Kamiya, S.; Odashima, S. *Gann* 70(5): 653-662; 1979.

The carcinogenicity of N-ethyl-N-nitrosourethan (ENUR) and N-amyl-N-nitrosourethan (ANUR) was tested in female Donryu rats. One group of 45 rats received 400 ppm ENUR in the drinking water for 6 days, followed by 200 ppm for 4 days. After a 7-day period without treatment, the animals received a 100 ppm ENUR soln (15-20 ml/rat/day) for life. Another group of 54 rats received a 400 ppm ANUR soln (15-20 ml/rat/day). A third group of 14 rats was treated topically with 0.03 ml ENUR 2x/wk. All rats had died by the 385th day of the experiment. Of the 35 rats given ENUR po, all developed tumors in the forestomach, 28 in the esophagus, 25 in the duodenum, 16 in the oral cavity and pharynx, and 18 in the liver. Topical application of ENUR also resulted in tumors in the forestomach (13/13), skin (11/13), and liver (1/13). Of the rats given ANUR, 39/40 developed tumors in the esophagus, 37/40 in the oral cavity and pharynx, and 31/40 in the forestomach. Comparison of these results with those induced by N-methyl-N-nitrosourethan, N-propyl-N-nitrosourethan, and N-butyl-N-nitrosourethan (BNUR) indicated that the incidence of tumors in the esophagus and oral cavity and pharynx increase in proportion to the mol wt of the alkyl chain, while the incidence of cancer of the forestomach decreases. The results also indicate that ENUR induces tumors both directly (skin tumors) and indirectly (tumors of the forestomach and liver). (21 refs)

79-6702 Bioassay of Sulfallate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Tech Rep Ser* (115): 59 pp.; 1978.

Sulfallate was investigated for possible carcinogenicity by adding it to the feed of Osborne-Mendel rats and B6C3F1 mice. Groups of 50 males and 50 females of each species received sulfallate at either of two concentrations: The time-weighted av high and low dietary concentrations were, respectively, 410 and 250 ppm for male rats, 404 and 250 ppm for female rats, 1,897 and 949 ppm for male mice, and 1,815 and 908 ppm for female mice. The dosing period of 78 wk was followed by an observation period of 25-26 wk for dosed rats, 33 wk for control rats, and 12-13 wk for dosed and control mice. From wk 30 to wk 78, an unusually high incidence of signs characteristic of eye irritation was observed in the dosed animals. Statistical analysis demonstrated that sulfallate administration was associated with increased incidences of mammary adenocarcinomas in female rats and of stomach and thyroid neoplasms in male rats. There were significant positive associations between dose incidence of mammary adenocarcinomas in female rats and between dose and incidence of tumors in male rats. In mice, long-term sulfallate administration was associated with increased incidences of neoplastic lesions including mammary adenocarcinomas in females; squamous cell carcinomas of the skin, adnexal tissues, and stomach in males and females; lung tumors in males and females; and hepatocellular carcinomas in females. Sulfallate administration was also associated with a significantly increased incidence of alveolar/bronchiolar neoplasms in male mice and of mammary adenocarcinomas without and with squamous metaplasia in female mice. Rare esophageal tumors (ie, one papilloma and two squamous cell carcinomas) occurred in high-dose rats but not in control and uncommon skin, and forestomach carcinomas were observed in sulfallate-treated mice. (17 refs)

79-6703 Role of Hormone Imbalance in Transplacental Carcinogenesis Induced in Syrian Golden Hamsters by Sex Hormones. (Eng) Rustia, M. (Eppley Inst. Res. Cancer, Univ.

Nebraska Medical Center, 42nd St. and Dewey Ave., Omaha, NE 68105). *Natl Cancer Inst Monogr* (51): 77-87; 1979.

Single, simultaneous doses of ethylurea (EU: 100 mg/kg) and NaNO_2 (50 mg/kg), precursors of the carcinogen ethylnitrosourea (ENU), were administered to pregnant Syrian golden hamsters by intragastric intubation on days 12, 13, 14, or 15 of gestation. A progressively increasing high incidence of peripheral nervous system (PNS) tumors occurred in progeny of these hamsters. The incidence was higher in female progeny than in males. In further experiments, multiple doses of 100 mg/kg EU and 50 mg/kg NaNO_2 were administered to pregnant females from days 12-15. Total amounts equaled 400 mg/kg EU and 200 mg/kg NaNO_2 . Female progeny again developed a greater number of PNS tumors than the males. At 60 wk of age, the PNS tumor incidence was 64% in females, with 3.8 tumors/animal, and 12.5% in males at a rate of 1 tumor/animal. By 60 wk all females were dead, but 69% of the males had survived. Observation extended through the male life span (108 wk) revealed that at death 56.3% of the males had developed tumors. Thus, the overall tumor incidence was similar in both sexes, but female progeny developed a significantly greater number of tumors/animal (3.8 vs 1.4) within a significantly shorter latency period (41 vs 72 wk). In another series of studies, progeny were gonadectomized at 5 wk of age. Orchidectomized males developed a significantly higher tumor incidence (85% vs 56%) and a significantly greater tumor multiplicity (3.8 vs 1.4) within a shorter latency period (72 vs 51 wk). The percentage of all tumor types was also greater in gonadectomized males than in females. Females showed an increase in different tumor types, but they had fewer tumors/animal. These results suggest that endogenously generated androgens may inhibit PNS tumor development. Adult hamsters treated with EU and NaNO_2 at doses 10 times greater than those given in the transplacental experiments had PNS tumor incidence three- to fourfold lower than that of prenatally exposed progeny; only 18%-20% of the adults developed PNS tumors. The tumor spectrum was wider, however, and the overall tumor incidence was as high as that in transplacentally exposed or gonadectomized progeny. It was concluded that neural tissues become less sensitive to neoplastic change during the postnatal period, but that susceptibility of other tissues increased. To simulate human prenatal exposure to diethylstilbestrol (DES), pregnant hamsters were given a single dose of 20-40 mg/kg DES on day 15 of gestation or two consecutive doses of 20 or 40 mg/kg on days 14 and 15. Over 28% of female progeny exposed to a single dose and 50% exposed to two doses developed reproductive tract neoplasms. Metaplastic, hyperplastic, and dysplastic lesions increased with increased DES exposure. Male progeny developed tumors of the epididymis (70%) and of the testis (40%). (32 refs)

79-6704 Methylation of Neuronal and Glial Macromolecules by Methylnitrosourea and Dimethylnitrosamine In Vivo. (Eng) Hemminki, K. (Inst. Occupational Health, Haartmaninkatu 1, SF-00290 Helsinki 29, Finland); Savolainen, H. *Toxicol Lett* 4(4): 287-293; 1979.

Rats were injected ip with a mixture of 50 μCi of radioactive methylnitrosourea (1.0 Ci/mmol) and dimethylnitrosamine (25.7 mCi/mmol), and neuronal and glial cell fractions were separated from brain tissue after 4 hr, 72 hr and 10 days. DNA, RNA and protein were purified; and specific radioactivity was determined. All labeling times with methylnitrosourea neuronal nucleic acid were methylated to higher (1.5-2.0:1) specific radioactivity than glial nucleic acids. 7-Methylguanine appeared to be the major purine adduct and O⁶-methylguanine a minor adduct in the two cell fractions. The proportion of O⁶-methylguanine was equal in

the two cell fractions. With dimethylnitrosamine, glial macromolecules were methylated to a greater extent than neuronal macromolecules. Neuronal cells appear to be inactive in the metabolism of dimethylnitrosamine. The level of methylation in brain tissue by dimethylnitrosamine was of a lower order than in liver tissue. (18 refs)

79-6705 Unscheduled DNA Synthesis in Isolated Hepatic Nuclei After Treatment of Rats with Methylnitrosourea In Vivo. (Eng) Kaufmann, W. K. (Lab. Radiobiology, Univ. California, San Francisco, CA 94143); Kaufman, D. G.; Grisham, J. W. *Biochem Biophys Res Commun* 91(1): 297-302; 1979.

Unscheduled DNA synthesis was measured in vitro in nuclei isolated from nonreplicating liver cells from male F344 rats treated iv with methylnitrosourea (MNU). MNU significantly stimulated the capacity of such nuclei to incorporate deoxyribonucleoside-5'-triphosphate precursors into nuclear DNA in vitro ($p < 0.01$). Max rates of DNA synthesis were observed in nuclei isolated from livers 10 and 45 min after injection of 0.25 mmole/kg MNU. In nuclei isolated 12 hr after treatment, the rate of endogenous DNA synthesis had returned to near control levels. The response was dependent on the dose of MNU between 0.05 and 0.10 mmole/kg, but there appeared to be a plateau in the effect at doses > 0.10 mmole/kg. The MNU-activated nuclear DNA synthesis was a template-directed, gap-filling process. It appears to represent the continuation in vitro of unscheduled, reparative DNA synthesis initiated in damaged cells in vivo. (18 refs)

79-6706 Effect of N-Carboxymethyl-N-Nitrosourea on Viability and Mutagenic Response of Repair-deficient Strains of *Escherichia coli*. (Eng) Yoshikawa, K. (Dept. Mutagenesis, Natl. Inst. Hygienic Sciences, Kamiyoga 1-18-1, Setagaya-ku, Tokyo 158, Japan); Uchino, H.; Yamamoto, M.; Yamada, T.; Tanimura, A.; Kondo, S. *Gann* 70(5): 705-708; 1979.

Under simulated human gastric conditions, the glycoamine found in meats is converted into N-carboxymethyl-N-nitrosourea (CMNU) by reaction with sodium nitrite. CMNU was tested for mutagenicity and lethal activity with a set of isogenic strains of *Escherichia coli* possessing the same auxotrophic marker but different DNA-repair capacities. Both strains NG30 (*recA*⁻) and R15 (*polA*⁻) were far more sensitive to lethality induced by CMNU than were H/r30R (wild) and Hs30R (*uvrA*⁻) strains. The *uvrA*⁻ strain was more sensitive to mutation induction by CMNU than the wild and *polA*⁻ strains, but the *recA*⁻ strain was barely susceptible to CMNU mutation. It was concluded that the major cause of CMNU lethality in *E. coli* is different from that of mutation induction. (17 refs)

79-6707 Comparative Binding Studies on 1,1'-Ethylene-bis(1-nitrosourea) and Some 1-Alkyl-1-nitrosoureas with Nucleic Acids and Proteins In Vitro. (Eng) Morimoto, K. (Div. Medical Chemistry, Natl. Inst. Hygienic Sciences, Kamiyoga 1-18-1, Setagaya-ku, Tokyo 158, Japan); Tanaka, A.; Yamaha, T. *Gann* 70(5): 693-698; 1979.

The binding capacities of 1,1'-ethylene-bis(1-nitrosourea) (EBNU), 1-methyl-1-nitrosourea (MNU), 1-ethyl-1-nitrosourea

(ENU), and 1-propyl-1-nitrosourea (PNU), labeled with ^{14}C in the carbonyl or alkyl group, to nucleic acids, proteins, and synthetic biopolymers was compared in vitro. The binding of radioactivity from the labeled ^{14}C -carbonyl group of EBNU to proteins and polypeptides was at least twofold higher than that of MNU, ENU, and PNU. The alkylating activity to DNA decreased in the order of MNU, EBNU, and ENU. PNU did not bind with DNA to any detectable extent. Binding of radioactivity from EBNU-[ethylene- ^{14}C] was found in histone, but binding from each mono-N-nitrosourea-[alkyl- ^{14}C] did not occur. The effect of various amino acids on the binding of ^{14}C -EBNU and ^{14}C -MNU to polylysine and poly(G) was studied. All the amino acids tested had no or little effect except cysteine. The binding of radioactivity from the carbonyl- ^{14}C group of EBNU and MNU to polylysine decreased about 30% and 20%, respectively, in the presence of equimolar amounts of cysteine. Cysteine completely inhibited the binding of radioactivity from EBNU[ethylene- ^{14}C] to polylysine and poly(G), but binding of radioactivity from MNU[methyl- ^{14}C] to poly(G) was inhibited only slightly. (20 refs)

- 79-6708 1-Methyl-1-Nitrosourea Induction of Cancer in a Localized Area of the Syrian Golden Hamster Trachea. (Eng) Grubbs, C. J. (Div. Life Sciences, I.I.T. Res. Inst., 10 West 35th Street, Chicago, IL 60616); Moon, R. C.; Norikane, K.; Thompson, H. J.; Becci, P. J. *Prog Exp Tumor Res* 24: 345-355; 1979.

A respiratory tumor model was developed that permits the rapid induction of cancer in a localized area of the hamster trachea. The predominant type of cancer induced was combined epidermoid and adenocarcinoma similar to bronchogenic carcinoma in humans. The intratracheal instillation of either 0.5% or 2.5% 1-methyl-1-nitrosourea 1x/wk for 15 consecutive wk induced a 68% and 33% incidence of tracheal cancers, respectively, within 6 mo. This treatment regimen permits tumor development in a large number of animals without toxic effects and thus provides a model for use in the rapid evaluation of newly synthesized anticancer compounds. (20 refs)

- 79-6709 Mechanism of Perinatal Tumor Induction by Neuro-Oncogenic Alkylnitrosoureas and Dialkylaryltriazenes. (Eng) Kleihues, P. (Abteilung Neuropathologie, Pathologisches Institut der Universität Freiburg, 78 Freiburg, W. Germany); Cooper, H. K.; Buecheler, J.; Kolar, G. F.; Diessner, H. *Natl Cancer Inst Monogr* (51): 227-231; 1979.

The methylation by 3,3-dimethyl-1-phenyltriazenes and N-methyl-N-nitrosourea (MNU) of DNA from BD-IX rat liver and brain was investigated at various developmental stages. Following a single sc injection of [^{14}C]DMPT (100 mg/kg, 15 hr survival time) in pregnant rats (21st day of gestation), the extent of methylation of purine bases was similar in fetal liver and brain. During postnatal growth, this treatment resulted in an increasingly preferential methylation of liver DNA. In 30-day-old BD-IX rats, 7-methylguanine concentrations were approx eight times higher in liver than in brain DNA. This suggested that during prenatal development, both liver and brain DNA are transplacentally methylated by a proximate carcinogen produced by maternal organs. After a single ip injection of [^3H]MNU (10 mg/kg) to 10-day-old rats, O⁶-methylguanine was removed more rapidly from hepatic than from cerebral DNA. Within 1 wk of the injection, the brain-to-liver ratio for O⁶-methylguanine increased from 1.4 to 98.

These results are compatible with the hypothesis that the deficiency of various organs for repair excision of O⁶-alkylguanine from DNA correlates with their susceptibility to malignant transformation by monofunctional alkylating carcinogens. (25 refs)

- 79-6710 Studies with a New Experimental Model in Respiratory Carcinogenesis. (Eng) Nettesheim, P. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Yarita, T. *Prog Exp Tumor Res* 24: 330-344; 1979.

A new experimental model for respiratory carcinogenesis was studied using hamsters and N-nitroso-N-methylurea (NMU). After 5-10 exposures to 1% NMU with the new tracheal exposure device, the tracheal epithelium changed to a low cuboidal epithelium with areas of flat and 'bizarre' cells. Other areas showed hyperplastic and hypertrophic epithelium with small squamous metaplasias. These changes were more widespread and severe after 15-20 exposures, and small early invasive carcinomas were observed in many animals after 20 exposures. In general, the toxic changes were more severe in animals receiving two exposures/wk than in those exposed only once/wk. With 0.5% NMU, the mucosal changes were milder; and with 0.25% NMU, changes other than mild hyperplasia were rare. With increasing numbers of exposures to 1% NMU, the number of tumor-bearing and invasive-tumor-bearing animals increased and the tumor induction time decreased. The tumor incidence was only 10%-20% lower after exposure to 0.5% NMU than after similar exposure to 1% NMU, but the same mean tumor induction times were 10-14 wk longer with the lower concentration. Benign polyps and papillomas comprised 40% or more of the tumors in the low-dose groups, whereas invasive carcinomas comprised 50%-70% of all tumors in the high-dose groups. Of the invasive carcinomas, 50% were epidermoid carcinomas and 20% each were adenocarcinomas and large cell carcinomas. Small cell and squamous type carcinomas in situ were observed, as were anaplastic large cell and small cell carcinomas. Distant metastases were not observed. Most of the neoplasms occurred in the region between the sixth and thirteenth tracheal rings. (8 refs)

- 79-6711 Bioassay of Trimethylthiourea for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (129): 44 pp.; 1979.

The possible carcinogenicity of trimethylthiourea was tested by feeding groups of 50 F344 rats or B6C3F1 mice of each sex a diet containing either of two concentrations of the test chemical (500 and 250 ppm for rats; 1,000 and 500 ppm for mice) for 77 wk. Groups of 20 matched animals fed a normal diet were used as controls. The treatment period was followed by an observation period lasting 29 wk for rats and 14 wk for mice. No correlation between treatment and mortality was observed. The mean body wt of high-dose female rats and treated mice of both sexes was significantly lower than those of control animals. A significantly increased incidence of follicular-cell carcinomas of the thyroid and of combined follicular-cell carcinoma and follicular-cell adenoma was observed in female rats; these incidences were dose-related. It is concluded that under the conditions of the assay, trimethylthiourea is carcinogenic in female F344 rats. (24 refs)

- 79-6712 Synthesis of 1-(2-Hydroxyethyl)-nitrosourea and Comparison of Its Carcinogenicity with That of 1-Ethyl-1-nitrosourea. (Eng) Swenson, D. H. (Natl. Center Tox-

icological Res., Jefferson, AR 72079); Frei, J. V.; Lawley, P. D. *J Natl Cancer Inst* 63(6): 1469-1473; 1979.

1-(2-Hydroxyethyl)-1-nitrosourea (HNU) was prepared by the action of nitrosyl chloride on (2-hydroxyethyl)urea, and its carcinogenicity for female C57BL/Cbi mice was compared with that of 1-ethyl-1-nitrosourea (ENU). The ether-water partition coefficient of the HNU obtained was 0.06, compared with a previously reported value of 0.39. Similarly, the half-life of HNU following hydrolysis at pH 7 and 37 C for 1 hr was 0.17 hr, compared with a much higher value previously reported. There was also a lack of complete agreement between the physical and chemical data obtained for the HNU and that previously reported. The potency of HNU in inducing thymic lymphocytic lymphomas was close to that of ENU. The slope of the dose-response curve for HNU (log scales) was 2.4, indicating that tumor induction was a 2- to 3-hit process. (27 refs)

79-6713 Bioassay of Nithiazide for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* 152(146): 46 pp.; 1979.

A bioassay of nithiazide for possible carcinogenicity was conducted by administering the test chemical in feed to F344 rats and B6C3F1 mice of either sex at either of two concentrations (1,250 and 625 ppm for rats, 5,000 and 2,500 ppm for mice) for 113 wk. Because of a shortage of nithiazide, the animals were fed a normal diet for a period of 9 wk in the course of the assay. No correlation between treatment and mortality was observed, but treatment-related mean body wt depression was noted. A significantly high incidence of hepatocellular carcinoma was observed in the high-dose male mice; a nonsignificantly higher incidence was observed in female mice. A significantly increased incidence of a combination of mammary and skin fibroadenomas and cystadenomas NOS in the high-dose female mice and of mammary neoplasms in female rats was observed. It is concluded that, under the conditions of the assay, nithiazide is carcinogenic for B6C3F1 mice of both sexes and for female F344 rats. (14 refs)

79-6714 Induction of Tumors by Direct Injection of *N*-Ethyl-*N*-nitrosourea Into the Amniotic Space of the Mouse Fetus. (Eng) Rossi, L. (Inst. Oncology, Univ. Genova, Viale Benedetto XV, 10 Pad. B-1632, Genoa, Italy); Mollner, T.; Munhall, A.; Shubik, P. *J Natl Cancer Inst* 63(4): 987-989; 1979.

An *N*-ethyl-*N*-nitrosourea (ENU) solution was injected into the amniotic space of Swiss mouse fetuses. Nine-day-old embryos were exposed to 2 and 4 μ g ENU and died within the first 4 wk of life. The injection of 4 μ g ENU into 11-day-old fetuses induced a 10% lung tumor incidence, whereas the injection of 16 μ g injected at 12, 15, or 16 days resulted in lung tumor incidences of 42%, 100%, and 84%, respectively. Fifty percent of 16-day fetuses exposed to 64 μ g of ENU died, and a lung tumor incidence of 89% was seen in the survivors. Histologic examination revealed that the tumors were alveogenic adenomas 1-7 mm in diameter. No tumors occurred in two saline-treated control groups. This biologic model could be used for testing chemical alkylating agents similar to ENU. (22 refs)

79-6715 Tissue Differentiation and Susceptibility to Embryonal Tumor Induction by Ethylnitrosourea in the Opossum. (Eng) Jurgelski, W. (Office Health Hazard Assessment

and Environmental Toxicology Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC 27709); Hudson, P.; Falk, H. L. *Natl Cancer Inst Monogr* (51): 123-158; 1979.

In two separate experiments, 532 opossums (*Didelphis virginiana* Kerr) bred in captivity were divided by litter into 10 age groups ranging from 1 day to 16 wk. In the first experiment, animals were given single po doses of approx 100 mg/kg ethylnitrosourea (ENU). In the second study, the same dose was given in four 25 mg/kg increments on alternate days. Controls received phosphate buffered saline (PBS) only. Histological examinations were made after death or sacrifice of the animals. Unilateral intraocular tumors developed in 5/58 animals given ENU between 1-3 wk of age. Four neoplasms were in males. The cells of origin appeared to be the nonpigmented epithelium of the nonsensory retina. The tumors were malignant teratoid medulloepitheliomas. Embryonal tumors of the kidney developed in 66/226 opossums exposed to ENU between birth and 6 wk of age. Probable cells of origin were the nephrogenic and stromatogenic stem cells of the kidney. The renal tumors exhibited characteristics of Wilms' tumor or nephroblastoma. Polycystic kidney was observed in some animals. Brain neoplasms, originating most frequently in the subependymal region of a lateral ventricle, were found in 12/198 animals given single doses of ENU between birth and 56 days of age. The neoplastic cells were neurons, and the tumors were gangliomas. Epithelial odontogenic neoplasms developed in 32/277 animals within 2 mo of ENU exposure. These tumors were analogous to ameloblastomas, and they arose at different stages of development from embryonic teeth, dental remnants, or buccal mucosa. (92 refs)

79-6716 Transplacental Effects of Ethylnitrosourea in a Nonhuman Primate, *Erythrocebus patas*. (Eng) Rice, J. M. (Experimental Pathology Branch, NCI, Bldg. 37, Room 3A09, Bethesda, MD 20205); Sly, D. L.; Palmer, A. E.; London, W. T. *Natl Cancer Inst Monogr* (51): 185-192; 1979.

Erythrocebus patas were established into breeding units of one male and two females. When females became pregnant, they received iv injections of 0.1 millimole (mmol)/kg (12 mg) of ethylnitrosourea (ENU) at 7-14 day intervals for carcinogenesis studies and 1.0 mmol/kg for toxicity studies. To study transplacental passage, a near-term pregnant female was given an iv injection of 0.1 mmol/kg ENU to which 0.68 mCi labeled ENU in 0.10 ml ethanol had been added. Blood samples were taken from the umbilical vein and the saphenous vein of the mother. The fetus was killed 15 min after the mother had received the injection, and tissue samples were removed from the fetus. Thirteen juveniles (four males and nine females) were given 0.1 mmol/kg ENU every 14 days for comparison with progeny exposed to ENU at 30, 50, and 60 days gestation. Repeated doses of ENU, given at 14-day intervals, were tolerated without apparent signs of toxicity by fetal, pregnant, and juvenile monkeys. During the latter two-thirds of pregnancy the interval could be reduced to seven days. Large single doses (1.0 mmol/kg) were tolerated by pregnant females but frequently resulted in abortion. These doses produced acute cytolytic damage to cells of the periventricular germinal matrix of the fetal brain. Studies with labeled ENU showed no placental barrier to this carcinogen. Specific activities were highest in fetal liver. As of December 1975, no tumors had been observed. (27 refs)

79-6717 2,5-Dithiobiurea. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (132): 1-48; 1979.

The carcinogenicity of 2,5-dithiobiurea (DTU), a component of photographic chemicals, was studied in Fischer 344 rats and B6C3F1 mice. DTU was incorporated into the rats' diet at 0.6% or 1.2% for 78 wk, and was added to the diet of the mice at 1.0% or 2.0% for 78 wk. A subchronic feeding study was also conducted. DTU treatment was associated with a decrease in mean body wt in mice but not in rats. No consistent pattern of clinical signs was observed in either species. Tumor incidence was not significantly increased in DTU-treated rats or male mice relative to untreated controls. The incidence of hepatocellular carcinoma increased significantly with dose in DTU-treated female mice and decreased significantly with dose in DTU-treated male mice. It is concluded that under the conditions of this bioassay, DTU is carcinogenic in female B6C3F1 mice but not in male B6C3F1 mice or male or female Fischer 344 rats. (21 refs)

79-6718 Bioassay of 1-Phenyl-2-Thiourea for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (148): 44 pp.; 1979.

1-Phenyl-2-thiourea (PTU) was tested for possible carcinogenicity by administering it in the diet of Fischer 344 rats and B6C3F1 mice at either of two concentrations (120 and 60 ppm for rats, 300 and 150 ppm for mice). Fifty males and 50 females of each species were used in each group with 20 males and females of each species as controls. Treatment resulted in a distinct depression of mean body wt in males and females of each group, but no significant positive association could be established between treatment and tumor incidence. Significantly accelerated mortality or other toxic effects were not observed in treated animals. It is concluded that, under the conditions of the assay, PTU is not carcinogenic to Fischer 344 rats or B6C3F1 rats. (19 refs)

79-6719 Tolazamide. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (51): 1-94; 1979.

The carcinogenicity of tolazamide, an oral hypoglycemic agent, for Fischer 344 rats and B6C3F1 mice was studied. Tolazamide was incorporated in the diet 5 days/wk for 103 wk at 5,000 or 10,000 ppm. Subchronic feeding studies were also conducted to estimate the max tolerated doses of tolazamide. Tolazamide treatment was associated with decreases in mean body wt in both rats and mice, but there were no other clinical signs of toxicity. Survival rates were higher among treated rats than among controls and lower among treated mice than controls. The incidences of C-cell adenomas and carcinomas of the thyroid were nonsignificantly increased in male rats compared with controls. All observed tumors were of types commonly found in the animal strains used, and there were no significant differences in tumor incidence among treated or control animals. It is concluded that under the conditions of this bioassay, tolazamide is not carcinogenic in Fischer 344 rats or in B6C3F1 mice. (14 refs)

79-6720 Acetohexamide. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (50): 1-92; 1979.

The carcinogenicity of dietary acetohexamide (AHA: 10,000 or 20,000 ppm) in Fischer 344 rats and B6C3F1 mice was studied in a

103-wk trial. Subchronic studies were also conducted to estimate the max tolerated doses of AHA. AHA feeding caused a dose-dependent decrease in mean body wt in both mice and rats, but no other clinical signs related to AHA administration were observed. The incidence of leukemia was greater among the AHA-treated rats than among the untreated controls, but the difference was significant only in the case of males given 10,000 ppm AHA. Most leukemias were of the undifferentiated mononuclear cell type, which commonly occurs spontaneously in Fischer 344 rats. Thus, the increased incidence of this disease in AHA-treated rats cannot clearly be associated with its administration. Lymphomas, which commonly occur in untreated B6C3F1 mice, occurred at a non-significantly higher frequency among AHA-treated male mice than among untreated male mice. It is concluded that under the conditions of this bioassay, AHA is not carcinogenic for Fischer 344 rats or B6C3F1 mice. (19 refs)

79-6721 In Vivo Studies in Syrian Golden Hamsters: A Transplacental Bioassay of Ten Nitrosamines. (Eng) Althoff, J. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Grandjean, C. *Natl Cancer Inst Monogr* (51): 251-255; 1979.

The carcinogenic effects of a single low dose of 10 nitrosamines, each administered sc, were determined in pregnant Syrian golden hamsters and their offspring. The compounds studied included dimethylnitrosamine, di-n-propylnitrosamine, di-n-butylnitrosamine, nitrosopiperidine, nitrosohexamethyleneimine, 2-hydroxypropyl-propyl-nitrosamine, methylpropylnitrosamine, di(2-hydroxypropyl)nitrosamine, and 4-hydroxybutyl-butyl-nitrosamine. Tumor incidences of all organ systems were almost always higher and latencies shorter in the mothers than in the offspring. Exceptions occurred in the respiratory system in which several compounds induced a low incidence of tumors in the offspring but none in the mothers. Fetal susceptibility appeared greatest toward the end of gestation. For bioassay purposes, transplacental exposure was less efficient than conventional adult treatment. (16 refs)

79-6722 Intake of Volatile Nitrosamines from Consumption of Alcohols. (Eng) Walker, E. A. (International Agency Res. Cancer, 150 cours Albert-Thomas, 69372, Lyon, Cedex 2, France); Castegnaro, M.; Garren, L.; Toussaint, G.; Kowalski, B. *J Natl Cancer Inst* 63(4): 947-951; 1979.

During epidemiologic studies concerning the relationship between esophageal cancer incidence and alcohol consumption in Normandy, France, volatile nitrosamine levels were determined in alcoholic beverages. Nitrosodimethylamine (NDMA) was found in most alcoholic drinks tested, with the exception of wine. The av level, about 2 µg/liter in beer, was higher than that for other drinks; the range was 0.2-8.6 µg/liter. Traces of nitrosodiethylamine were also detected in spirits and ciders. No significant increases in these levels were found after nitrosation. The calculation of daily alcohol intake in the study region showed that the main intake of volatile nitrosamine is from NDMA in beer. NDEA intake from cider is about one-third that of NDMA from all sources. (18 refs)

79-6723 Mutagenicity and Cytotoxicity of Nineteen Heterocyclic Mustards (ICR Compounds) in Cultured

Mammalian Cells. (Eng) Fuscoe, J. C. (Univ. Tennessee-Oak Ridge Graduate Sch. Biomedical Sciences, Oak Ridge, TN 37830); O'Neill, J. P.; Peck, R. M.; Hsie, A. W. *Cancer Res* 39(12): 4875-4881; 1979.

The mutagenicity and cytotoxicity of 19 ICR compounds, including 6 reported previously, were determined in the Chinese hamster ovary hypoxanthine-guanine phosphoribosyltransferase system. A phenotypic expression time of 9 days was used, based on the 7- to 9-day expression times required for ICR 170 and 191. Thirteen of these compounds were mutagenic. At equimolar concentrations, the compounds with the tertiary amine-type side chain (ICR 217, 340, 355, 368, 170, and 292) were more mutagenic than the compounds with the secondary amine-type side chain (ICR 449, 371, 191, and 372). All secondary amine types reached a "plateau" in their concentration-dependent mutagenesis curves at 3 to 4 μ M. Shortening of the side chain by one carbon (ICR 171) reduced mutagenicity. Substitution of a sulfur atom for a nitrogen in the side chain (ICR 342) increased both mutagenicity and cytotoxicity. The presence of two 2-chloroethyl groups on the side chain (ICR 220) resulted in greatly increased cytotoxicity and mutagenicity. With the 2-chloroethyl group of ICR 340, 372, 292, 191, or 170 replaced by a 2-hydroxyethyl group (ICR 340-OH, 372-OH, 292-OH, 191-OH, or 170-OH), a mutagenically inactive compound resulted which nevertheless remained toxic. Replacement of the amine linkage with an ether linkage (ICR 283) also yielded a mutagenically inactive compound. (18 refs)

79-6724 Effect of Chronic N,N-Diethylnitrosamine on the Excision of O⁶-Ethylguanine from Rat Liver DNA. (Eng) Margison, G. P. (Paterson Lab., Christie Hosp. and Holt Radium Inst., Manchester M20 9BX, England); Curtin, N. J.; Snell, K.; Craig, A. W. *Br J Cancer* 40(5): 810-814; 1979.

The effect of N,N-diethylnitrosamine (DEN: approx 10 mg/kg/day in drinking water for 5 or 10 wk) on the excision of O⁶-ethylguanine (O-EG) from the liver DNA of male Wistar rats was studied. The levels of 7-ethylguanine (7-EG) and 3-ethyladenine (3-EA) in the liver DNA of the rats given DEN for 5 wk (5-wk group) were higher than in untreated controls, and the 3-EA:7-EG ratio was decreased by 6% in the 5-wk group. 3-EA and 7-EG levels were slightly lower in the 10-wk group than in controls, and the ratio of 3-EA:7-EG was 6% higher in controls. The levels of O-EG were reduced by 60% and 90% in the 5-wk and 10-wk groups, respectively, compared with the control rats. The O-EG:7-EG ratios were 26% and 7% of the control values in the 5-wk and 10-wk groups, respectively. (24 refs)

79-6725 Tissue Differentiation as a Prerequisite for Transplacental Carcinogenesis in the Hamster Respiratory System, with Specific Respect to the Trachea. (Eng) Mohr, U. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, 3000 Hannover 61, W. Germany); Reznik-Schuller, H.; Emura, M. *Natl Cancer Inst Monogr* (51): 117-122; 1979.

Female Syrian golden hamsters (15 groups of six) were given a single sc injection of 45 mg diethylnitrosamine (DEN)/kg on one of the 15 days of pregnancy. An equivalent group treated on day 15 with the solvent (physiologic saline) alone served as a vehicle control. Both mothers and offspring surviving the weaning period were observed until spontaneous death. At autopsy, histological and ultrastructural studies were performed on sections of larynx

and trachea. In another experiment, 74 female Syrian golden hamsters were killed on each of the different days of pregnancy, and fetal trachea with lungs were excised and studied as in the experiment. Offspring of mothers receiving DEN on one of the first 11 days of pregnancy developed no respiratory tract tumors. A pronounced neoplastic response was found in young from mothers treated on one of the last four days of pregnancy. The tumor incidence increased to 95% in those animals treated on the 15th prenatal day. Most of the neoplasms were in the larynx and trachea; only a few were found in the nasal cavities and lungs. Mothers also showed a high incidence of tracheal and laryngeal tumors. These tumors were papillomas and papillary polyps. Nasal cavity tumors were adenocarcinomas and squamous cell carcinomas. All pulmonary tumors were bronchogenic adenomas. In the second experiment, histological examination revealed that the trachea separates from the embryonal esophagus between the 9th and 10th prenatal days. The largest number of mitotic figures were found on the 11th day. Since max carcinogenic effect of DEN was observed between days 12 and 15, carcinogenic and mitotic activity did not appear to be directly related. Electron microscopy revealed that cells were still poorly differentiated up to the 12th day of gestation. Beginning with the 12th day, a progressive condensation of heterochromatin was observed, and the first rough endoplasmic reticulum (RER) appeared. Since DEN requires conversion to its ultimate carcinogen before exhibiting carcinogenic effects, it was concluded that this process depended on appearance of the RER, which is known to bear the nonspecific enzymes needed for DEN conversion. (13 refs)

79-6726 Metabolism of Three Radiolabeled Pancreatic Carcinogenic Nitrosamines in Hamsters and Rats. (Eng) Gingell, R. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE 68105); Brunk, G.; Nagel, D.; Pour, P. *Cancer Res* 39(11): 4579-4583; 1979.

The in vivo metabolism and disposition of three radiolabeled N-nitrosamines which are carcinogenic for the pancreas of the hamster but not the rat have been examined. N-[1-¹⁴C]Nitrosobis(2-oxopropyl) amine (BOP), N-[1-¹⁴C]Nitrosobis(2-hydroxypropyl)amine (BHP), and their suggested proximate pancreatic carcinogenic metabolite N-[1-¹⁴C] nitroso-(2-hydroxypropyl) (2-oxopropyl)amine (HPOP) were administered ip to male Syrian hamsters or Wistar rats in doses of 10 or 100 mg/kg. The carcinogens were metabolized and exhaled as ¹⁴CO₂ to various extents somewhat proportional to their carcinogenic potency. More than 50% of the dose of BOP and HPOP was exhaled as ¹⁴CO₂; only 26% of the BHP dose was thus excreted, while 40% of it was excreted unchanged in the urine. Administered BOP was excreted to a small extent in the urine of both species as HPOP and BHP. No other nitrosamine metabolites were detected in urine. HPOP and BHP were detected in the pancreatic juice and bile of both species after administration of BOP and BHP. The results suggest that pancreatic ductular carcinogenesis in the hamster as a result of exposure to BOP is not due to secretion of carcinogenic metabolites in the pancreatic juice or reflux of bile containing nitrosamine metabolites into the ducts. Metabolic activation of the carcinogen(s) appears to be by an oxidative pathway. (25 refs)

79-6727 Experimentally Induced Pancreas Carcinoma After Choledochojunostomy. (Ger) Ruckert, K. (Chirurgische Universitätsklinik, Langenbeckstrasse 1, D-6500 Mainz, W. Germany); Klink, E.; Kloppel, G. *Langenbecks Arch Chir* 348(4): 261-268; 1979.

The significance of bile reflux in the development of pancreatic carcinoma after exposure to chemical carcinogens was tested in Syrian golden hamsters. Female hamsters (9 wk old) were given dihydroxy-di-n-propylnitrosamine (DHPN, 125 mg/kg body wt) for 15 wk via different routes. Two groups underwent choledochojejunostomy before DHPN in olive oil was injected sc (group 3) or given by stomach tube (group 4). In group 3, 1/20 hamsters had a pancreatic carcinoma and 6 had precancerous changes in the pancreas. One carcinoma and 3 hamsters with precancerous changes were found among 15 animals in group 4. In group 1 (DHPN sc, no surgery) 4/17 carcinomas (all in the body or tail of the pancreas) and 12 hamsters with precancerous lesions were found. In group 2 (DHPN by stomach tube, no surgery) carcinomas of the pancreatic head were seen in 9/16 animals, and 13 hamsters had precancerous changes. No cancerous or precancerous changes were found in the untreated or surgery-only control groups. These data indicate that the bile is a carrier of nitrosamines and a factor in the development of pancreatic carcinoma. (11 refs)

- 79-6728 The Morphologic and Biologic Patterns of Chemically Induced Pancreatic Adenocarcinoma in Syrian Golden Hamsters After Homologous Transplantation. (Eng) Takahashi, M. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Runge, R.; Donnelly, T.; Pour, P. *Cancer Lett* 7(2/3): 127-133; 1979.

A pancreatic adenocarcinoma induced by N-nitrosobis(2-oxopropyl)amine (2.5 mg/kg body wt, injected sc 1x/wk for 20 wk) in the Syrian golden hamster was successfully transplanted to a homologous host by sc inoculation through 10 successive passages. The rate of tumor take increased progressively with each generation from 60% to 100%, while the latency period after inoculation was reduced simultaneously from 6 wk to 1 wk in the second and following passages. The tumors grew rapidly, ulcerated the overlying skin, and metastasized to the regional lymph nodes and lungs. Most animals died with multiple lung metastases between the 5th and 20th wk. All transplanted tumors and their metastases retained the pattern of the original well-differentiated adenocarcinomas. (12 refs)

- 79-6729 Determination of Volatile Nitrosamines in Crops and Soils Treated with Dinitroaniline Herbicides. (Eng) West, S. D. (Lilly Res. Lab., Div. Eli Lilly and Company, Greenfield, IN 46140); Day, E. W. *J Agric Food Chem* 27(5): 1075-1080; 1979.

Solvent extraction procedures were developed for the routine determination of the volatile nitrosamines N-nitrosodi-n-propylamine (NDPA) and N-nitroso-N-n-butyl-N-ethylamine in crops, soils, and water. Plant tissue was extracted with methanol and soil with methanol/water (3:1). The extracts were purified by liquid-liquid extraction and alumina column chromatography, and residues were measured by gas chromatography-thermal energy analysis. The sensitivity of the method was 0.2, 0.05, and 0.01 ppb for NDPA in crops, soils, and water, respectively. No detectable nitrosamines were observed in crops treated with the herbicides trifluralin, benefin, or oryzalin. (24 refs)

- 79-6730 p-Nitrosodiphenylamine. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (190): 1-49; 1979.

The carcinogenicity of p-nitrosodiphenylamine (NDPA), a vulcanization accelerator and chemical intermediate, was studied in Fischer 344 rats and B6C3F1 mice. NDPA was added to the rats' diet at 2,500 or 5,000 ppm for 78 wk; for mice, the dose was 5,000 ppm for 40 wk followed by 2,500 ppm for 17 wk, or 10,000 ppm for 40 wk followed by 0 ppm for 7 wk followed by 5,000 ppm for 10 wk. Subchronic feeding studies were also conducted. In mice but not rats, mortality was significantly associated with NDPA dose. Dose-related decreases in body wt were observed among treated rats. In male rats, the incidence of hepatocellular carcinomas and neoplastic liver nodules increased significantly with NDPA dose, and there was also a positive association between drug dose and the incidence of alveolar/bronchiolar adenomas. The latter finding was of questionable significance. Tumor incidence was not significantly increased in NDPA-treated female rats or female mice. The incidence of hepatocellular carcinomas was significantly higher among male mice given the lower doses of NDPA than among their controls. It is concluded that under the conditions of this bioassay, NDPA is carcinogenic in male B6C3F1 mice and male Fischer 344 rats, but not in females of either species. (18 refs)

- 79-6731 A Technique for Multiparametric Analysis of Hemodynamic Changes in Rat Urinary Bladder During Carcinogenesis by N-Butyl-N-(4-hydroxybutyl)nitrosamine. (Eng) Lurie, A. G. (Dept. Oral Diagnosis, Div. Oral Radiology, Univ. Connecticut Health Center, Farmington, CT 06032); Rippey, R. M.; Conran, P. B.; Tatematsu, M.; Ito, N. *Gann* 70(5): 717-718; 1979.

A technique was developed for the simultaneous study of histopathology and vascular volume, permeability, and perfusion in rat urinary bladder during experimental carcinogenesis. Male Wistar rats received 0.05% N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN) in the drinking water for 8 wk and were sacrificed 2-40 wk after the start of BBN treatment. At sacrifice, each rat received an injection of rat blood labeled with ^{51}Cr and ^{125}I -human serum albumin (HSA) iv and $^{86}\text{RbCl}$ iv 1 hr later. The bladder was excised 90 sec after RbCl injection. Fractional distributions of ^{51}Cr -RBC, ^{125}I -HSA, and $^{86}\text{RbCl}$ were used to determine vascular volume, permeability, and perfusion, respectively. At wk 2, there was a diffuse epithelial hyperplasia. By wk 20, marked papillary hyperplasia was observed, and transitional cell carcinoma occupied the entire bladder lumen by wk 40. Bladder vascular volume, permeability, and perfusion increased initially, peaking at 2-8 wk. Perfusion remained at this level, while volume and permeability decreased sharply after termination of BBN treatment. Volume then increased from 20 to 35 wk, and permeability increased from 30 to 35 wk. Early increases in vascular volume and permeability may be due to neovascularization secondary to the effect of BBN. Late increases probably represent vascular responses to secretion of an angiogenesis factor from malignant cells. The sustained increase in vascular perfusion suggests the existence of alterations in transendothelial nutrient movement caused by BBN. (5 refs)

- 79-6732 Mutagenic and DNA-damaging Effects of N-Alkyl-N-(α -acetoxyalkyl) nitrosamines, Models for Metabolically Activated N,N-Dialkylnitrosamines. (Eng) Mochizuki, M. (Tokyo Biochemical Res. Inst., Takada 3-41-8, Toshima-ku, Tokyo 171, Japan); Suzuki, E.; Anjo, T.; Wakabayashi, Y.; Okada, M. *Gann* 70(5): 663-670; 1979.

Mutagenic and DNA-damaging effects of a series of N,N-dialkylnitrosamines monosubstituted at the α -carbon with an acetoxy group were tested in *Salmonella typhimurium*, *Escherichia coli*, and *Bacillus subtilis* in the absence of metabolic activation. The compounds included eight N-alkyl-N-(acetoxymethyl)nitrosamines (alkyl = methyl, ethyl, propyl, isopropyl, *sec*-butyl, or *tert*-butyl) and N-butyl-N-(1-acetoxybutyl)nitrosamine. All the compounds except that with a *tert*-butyl group gave positive results in all tests. Presumed release of alkyl cations from the corresponding α -acetoxy derivatives by hydrolysis and heterolysis caused mutagenic and DNA-damaging effects in the bacteria. Structure-activity correlation of the compounds was noted in these tests and discussed in regard to the mutagenicity with metabolic activation and the carcinogenicity of N,N-dialkylnitrosamines. The results support the hypothesis that α -carbon hydroxylation is one probable mechanism involved in the metabolic activation of N,N-dialkylnitrosamines. (35 refs)

- 79-6733 Development of Urinary Bladder Cancer in the Rat. (Eng) Kunze, E. (Pathologisches Institut der Universität, Gosslerstrasse 10, 3400 Gottingen, W. Germany). *Curr Top Pathol* 67: 145-232; 1979.

Morphological, enzyme histochemical, and autoradiographic methods were used to study carcinogenesis in the bladder mucosa of the rat following the application of the carcinogens di-N-butylnitrosamine, N-butyl-N-(4-hydroxybutyl)-nitrosamine, and N[4-nitro-2-furyl]-2-thiazolylformamide. Transitional cell carcinomas developed mainly through successive stages of transformation. The first stage consisted of a focal irreversible loss of alkaline phosphatase activity in histologically and cytologically normal urothelium. These areas were considered to be preneoplastic in that papillomas developed from such areas via enzyme-deficient hyperplasias after marked proliferative activity of enzyme-deficient urothelial cells. Most papillomas and carcinomas also showed a loss of alkaline phosphatase activity. Most carcinomas developed by way of malignant transformation of preexisting papillomas or their precursors, the papillary hyperplasias. The transition into focally malignant growth occurred in a stepwise manner through different successive stages of transformation. These stages consisted of a focal, sharply defined cellular atypia, followed by the development of carcinomas *in situ* and then by circumscript infiltrative growth. After transformation was initiated at the molecular level, the successive development of each stage occurred independently of further carcinogen treatment. The number of papillomas with transformation stages increased with the length of exposure and induction time, but these factors had no influence on proliferative activity. Transitional cell carcinomas usually developed from papillomas, but they seldom developed from primary carcinomas *in situ*. The spectrum of carcinomas induced included all types known to occur in humans. The adenocarcinomas originated from glandular metaplasia, and the squamous carcinomas developed from squamous metaplasia within completely developed transitional cell carcinomas. (125 refs)

- 79-6734 Analysis of Nitrosamines in Aqueous and Biological Fluids Based on Measurement of Photochemically Liberated Nitrite. (Eng) Musson, D. G. (Dept. Pharmaceutical Chemistry, Univ. Kansas, Lawrence, KS 66045); Sternson, L. A. *J Pharm Sci* 68(9): 1159-1162; 1979.

A method for the analysis of nitrosamines in aqueous solution and in blood, plasma, and rat liver microsomal suspensions is

described. N-nitrosopyrrolidine, N-nitrosodimethylamine, and N,N-diethanolnitrosamine were used as model compounds. The method is based on photochemical degradation of the nitrosamine in a controlled environment to yield the corresponding amine and nitrite ion, and the latter is subsequently used to form a chromophoric or fluorescent product. The analysis scheme is a modular three-component system consisting of a column to remove contaminating nitrite prior to photolysis, a photochemical reactor, and a chemical reactor. Additional modules are used to accommodate biological samples or large-volume (5-50 ml) aqueous samples. Because of intersubstrate variability in the photochemical decomposition rate and overall nitrite yield, the structure (ie, photochemical behavior) of the particular nitrosamine in the samples must be known prior to analysis. With a colorimetric readout, the sensitivity for analysis of N-nitrosopyrrolidine was 800 ng/ml for a 5-ml sample, and the measurement precision was $\pm 6\%$ in the biological fluids. Fluorometric analysis improved sensitivity to 4 ng/ml with a precision of $\pm 10\%$ in biological media. (18 refs)

- 79-6735 An Investigation into the Cytogenetic Damage Induced by the Coccidiostatic Agents Amprolium, Carbadox, Dimetridazole and Ronidazole. (Eng) Oud, J. L. (Dept. Cytogenetics and Population Genetics, Inst. Genetics, Univ. Amsterdam, Kruislaan 318, 1098 SM Amsterdam, Netherlands); Reutlinger, A. H.; Branger, J. *Mutat Res* 68(2): 179-182; 1979.

The mutagenicity of amprolium, dimetridazole, and ronidazole (coccidiostatic agents added to poultry feed, and carbadox (added to pig feed) were studied. Of the four agents, only carbadox (52.5-525 mg/kg) induced significant numbers of micronucleated polychromatic RBC in male and female mice following a single ip injection. Carbadox (210 mg/kg) also significantly increased the number of chromatid aberrations in mice 24-36 hr following a single ip dose; the maximal effect was observed 30 hr after treatment. Further investigations concerning the clastogenic potential of carbadox are warranted. (8 refs)

- 79-6736 Carcinogenicity of N-Nitroso-Ethylenethiourea in Female Mice. (Eng) Moriya, M. (Inst. Environmental Toxicology, Suzuki-cho 2-772, Kodaira-shi, Tokyo 187, Japan); Mitsumori, K.; Kato, K.; Miyazawa, T.; Shirasu, Y. *Cancer Lett* 7(6): 339-342; 1979.

Groups of 20 outbred ICR female mice (5 wk old) received N-nitroso-ethylenethiourea (N-nitroso-ETU: 0.66, 1.32, or 2.64 mg/wk \times 10, po) and were observed for 53 wk after the first dose. There was a significant increase in the number of mice with pulmonary and lymphocytic neoplasms; the incidence of these tumors appeared to be dose-dependent. There were no lung tumors in control mice compared with 4/20, 5/19, and 10/19 in groups given 0.66, 1.32, and 2.64 mg N-nitroso-ETU, respectively. There were no lymphocytic neoplasms in the control mice, but 2/20, 5/19, and 5/19 mice given 0.66, 1.32, and 2.64 mg of the test compound, respectively, developed such tumors. One control mouse and one mouse from the highest dosage group developed reticulum cell neoplasms. The higher dosage groups also developed tumors earlier than did the lower dosage groups. The results indicate that N-nitroso-ETU is carcinogenic in the lung and lymphoreticular system. (6 refs)

- 79-6737 In Vitro Transformation of Hamster Embryo Cells with a Glutamic Acid Pyrolysis Product. (Eng)

Takayama, S. (Dept. Experimental Pathology, Cancer Inst., 1-37-1, Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Hirakawa, T.; Tanaka, M.; Kawachi, T.; Sugimura, T. *Toxicol Lett* 4(4): 281-284; 1979.

The activity of the glutamic acid pyrolysis product 2-amino-6-methyldiprido[1, 2-a:3',2'-d]imidazole (Glu-P-1) was studied in vitro in a transformation assay with cryopreserved hamster embryo cells. Glu-P-1 was cytotoxic at a concentration of 50 µg/ml but induced morphological transformation of the cells at concentrations of 10 and 20 µg/ml. Glu-P-1 may be carcinogenic for experimental animals. (8 refs)

79-6738 Squamous-Cell Carcinoma Arising in a Basal-Cell Epithelioma Treated with 5-Fluorouracil. (Eng) Kurtis, B. (Dept. Dermatology, Veterans Admin. Hosp., Houston, TX); Rosen, T. *J Dermatol Surg Oncol* 5(5): 394-396; 1979.

The development of a squamous cell carcinoma within a basal cell epithelioma of a 33-yr-old man treated with 5-fluorouracil (5-FU: 800 mg instilled intralesionally over a 6-wk period) is reported. It is concluded that 5-FU may, in exceptional instances, precipitate the development of squamous cell carcinoma within or upon a preexisting basal cell epithelioma. Thus, this form of treatment cannot be recommended. (8 refs)

79-6739 Identification of S-(Carboxymethyl)-L-Cysteine and Thiodiglycolic Acid, Urinary Metabolites of 2,2'-Bis-(Chloroethyl)-Ether in the Rat. (Eng) Muller, G. (Institut für Staublungenforschung, Arbeitsmedizin, Universität Munster, Munster, W. Germany); Norpoth, K. *Cancer Lett* 7(5): 299-305; 1979.

The metabolism of the hepatocarcinogen 2,2'-bis-(chloroethyl)-ether (BCEE) was studied following ip injection (100 mg/kg body wt) in male SPF Wistar rats. S-(carboxymethyl)-L-cysteine (CMC) and thiodiglycolic acid (TGA) were identified by gas chromatographic-mass spectrometric measurements in the urine of BCEE-treated rats. It is therefore probable that BCEE is O-dealkylated by a mixed-function oxidation. The hepatocarcinogenic effect of BCEE may be explained by the liberation of chloroacetaldehyde in vivo, at TGA and CMC are metabolites of the latter chemical. (23 refs)

79-6740 Selectivity in Nucleoside Alkylation and Aalkylation in Relation to Chemical Carcinogenesis. (Eng) Moschel, R. C. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Hudgins, W. R.; Dipple, A. *J Org Chem* 44(19): 3324-3328; 1979.

The sites of benzylation of adenosine and guanosine by different benzylating agents were investigated to elucidate those properties of chemical reactivity that determine sites of reaction on nucleic acid constituents. The differences in chemical reactivity associated with reaction at ring nitrogen atoms as opposed to exocyclic sites were investigated by studying benzylation in different solvent systems. The differences in chemical reactivity associated with a preference for either the exocyclic O⁶ or N² positions in guanosine were investigated using benzylating agents with different leaving groups. The more aqueous solvents specifically promoted reaction on the exocyclic amino group in both the adenosine and guanosine

studies. The effects of the different leaving groups examined were such that the yield of ring-substituted product was always greater for the bromide than for the chloride, and that for the chloride was greater than that for the tosylate. With exocyclic substitution, yields were always lower for the chloride than for the bromide and tosylate. Exocyclic substitution for the tosylate was greater than that for the bromide in 20%-60% organic solvent in water but was less than that for bromide in the most aqueous solvent. Since potent carcinogens are found among agents that modify the O⁶ site on guanine residues and also among those that modify the N² site on guanine residues, the results suggest that a limited dependence on or susceptibility to, nucleophilicity is enough to render a reactive chemical potentially carcinogenic. (37 refs)

79-6741 Bioassay of Methyl Parathion for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (157): 112 pp.; 1979.

Methyl parathion was tested for possible carcinogenicity in F344 rats and B6C3F1 mice. Groups of 50 rats or mice of each sex received the test chemical in feed at one of two concentrations (20 or 40 ppm for rats; 62.5 or 125 ppm for female mice and for male mice initially; doses reduced to 20 and 50 ppm for male mice on wk 37, due to excessive wt loss) for 105 wk (rats) or 102 wk (mice). Groups of matched animals fed a normal diet were used as controls. Mean body wt in rats and mice of both sexes were significantly lower than those of controls throughout the assay. No correlation between treatment and survival (except for an increased mortality in the high-dose female rats) or between treatment and tumor incidence were observed. It is concluded that, under the conditions of the assay, methyl parathion is not carcinogenic in F344 rats and B6C3F1 mice of either sex. (22 refs)

79-6742 Reactions of N-Methyl-N-Nitrosobenzylamine and Related Substrates with Enzyme-containing Cell Fractions Isolated from Various Organs of Rats and Mice. (Eng) Schweinsberg, F. (Hygiene-Institut der Universität, Silchesterstr. 7, D-7400 Tübingen, W. Germany). *Cancer Lett* 7(2/3): 115-120; 1979.

The metabolism of N-methyl-N-nitrosobenzylamine (MNBA), N-methyl-N-nitroso-(α -phenyl)-ethylamine (MNPE), and N-methyl-N-nitroso-(2-phenyl)-isopropylamine (MNPI) was studied in microsomes isolated from various organs of female SIV 50 rats and NMRI mice. The metabolites were identified by gas chromatograph-mass spectrometry and high pressure liquid chromatography. The reaction of MNBA with mouse liver microsomes yielded benzaldehyde; MNPE yielded formaldehyde and acetophenone; and MNPI gave formaldehyde. The same qualitative results were obtained with microsomes of rat liver, rat esophagus, and mouse forestomach; but mouse liver microsomes generated more benzaldehyde from MNBA than did rat liver microsomes. Pretreatment of the mice with 0.1% phenobarbitone in the drinking water for 5 days increased the formation of benzaldehyde by a factor of 2. Microsomes from the rat organs showed decreasing activity in the sequence esophagus > forestomach > liver; for the mice the sequence was liver > forestomach. These results provide evidence that nitrosamine metabolism in rodents occurs through the oxidation of a C atom adjacent to the nitrogen function. The results, however, do not help to reconcile the metabolic findings and enzyme activities with the established tissue and species specificities for the carcinogenicity of the compounds investigated. (7 refs)

79-6743 Nucleic Acid Base and Carcinogen Metabolite Specificities During Intercalative Interactions Between DNA and 4-Nitroquinoline-1-Oxide. (Eng) Ornstein, R. L. (Dept. Biochemical Sciences, Frick Lab., Princeton Univ., Princeton, NJ 08540); Rein, R. *Chem Biol Interact* 27(2/3): 291-311; 1979.

The biophysical properties of the intercalative interactions occurring between 4-nitroquinoline-1-oxide (4NQO) and its metabolites with DNA minihelices were studied. The initial intercalated-complex models were energy-minimized to obtain the favored geometrical arrangement for each of seven 4NQO metabolites (NO_2 , NO_2^- , N=O , NOH , NHOH , NH_2 , or NH^+ substituted at the 4-position of quinoline) in each of several different minihelices, and the energies were determined using the expanded-optimized empirical-potential method. The results indicate that intercalation of 4NQO or its metabolic intermediate forms probably precedes the covalent bond formation of the ultimate carcinogenic form with the DNA. The various intercalated quinoline metabolites do not generally enter into "strictly" parallel-planar stacked orientation. Intercalation is energetically permitted for six of seven metabolites studied, although intercalation into $\text{Pyr}(3'-5')\text{Pur}$ sequences is favored over $\text{Pur}(3'-5')\text{Pyr}$ sequences. The three metabolites that are more energetically favored to enter intercalation (NH^+ , NH_2 , N=O), are also known to enter into the greatest amount of covalent binding with DNA and its constituents, suggesting a two-step binding mechanism (intercalation followed by covalent binding). (42 refs)

79-6744 An In Vitro Chromosome Assay Using Cultured Rat-Liver Cells. (Eng) Dean, B. J. (Shell Res. Ltd., Shell Toxicology Lab., Sittingbourne, Kent ME9 8AG, England); Hodson-Walker, G. *Mutat Res* 64(5): 329-337; 1979.

An in vitro chromosome assay is presented which utilizes an epithelial-like cell line derived from rat liver. The cell line, designated RL₁, retains sufficient metabolic enzyme activity to detect chromosome damage induced by a variety of chemical mutagens and carcinogens without the incorporation of an extrinsic metabolizing system. The cells are grown on standard glass microscope slides, exposed to the test chemical, and processed in situ for metaphase analysis. In a small validation study, chromosome damage was detected in cultures exposed to the direct-acting agents methyl nitronitrosoguanine, 4-nitroquinoline-N-oxide, propylene oxide, epichlorohydrin, and 1,2:3,4-diepoxybutane and to compounds requiring metabolic activation, including cyclophosphamide, 2-acetylaminofluorene, 3-methylcholanthrene, and 7,12-dimethylbenz[a]anthracene. Negative results were obtained with pyrene and carbon tetrachloride. (6 refs)

79-6745 Isolation of Gram Quantities of Configurational Isomers of Cyclic Nitrosamines by Preparative Liquid Chromatography. (Eng) Singer, S. S. (Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD); Singer, G. M. *J Liq Chromatogr* 2(8): 1219-1228; 1979.

Two substituted cyclic nitrosamines, 2,6-dimethyl-N-nitrosomorpholine and 3,5-dimethyl-N-nitrosopiperidine, were separated into their component configurational isomers by preparative high-pressure liquid chromatography (HPLC). The use of HPLC made possible the collection of gram quantities of the materials, suitable for animal testing; this method made the isolation more rapid and

much easier than does the conventional open column chromatography method. (6 refs)

79-6746 Hepatic Microsomal Epoxidation of Bromobenzene to Phenols and Its Toxicological Implication. (Eng) Lau, S. S. (Dept. Pharmacology, Univ. Michigan Medical Sch., Ann Arbor, MI 48109); Zannoni, V. G. *Toxicol Appl Pharmacol* 50(2): 309-318; 1979.

The in vitro epoxidation of bromobenzene by liver microsomes from male Sprague-Dawley rats pretreated with phenobarbital (50 mg/kg/day, ip, for 5 days) was studied. Enzymatic analysis and gas chromatography showed the formation of o-bromophenol via bromobenzene-2,3-epoxide and the formation of p-bromophenol via bromobenzene-3,4-epoxide. Phenobarbital pretreatment caused significant increases in both pathways, whereas pretreatment with 3-methylcholanthrene or β -naphthoflavone caused a marked increase only in the 2,3-epoxide pathway. Multiple forms of cytochrome P-450 were responsible for the formation of o-bromophenol and p-bromophenol. (24 refs)

79-6747 2,4,6-Trichlorophenol. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (155): 1-115; 1979.

The carcinogenicity of dietary 2,4,6-trichlorophenol was tested in 6-wk-old F344 rats and B6C3F₁ mice. The rats and male mice were fed the test chemical at 5,000 or 10,000 ppm for 105-107 wk. The female mice received 10,000 or 20,000 ppm for 38 wk and 2,500 ppm or 5,000 ppm for an additional 67 wk. In male rats, lymphomas or leukemias occurred at incidences that were dose-related and were significantly higher in the groups that received the low and high doses than in the controls (4/20, 25/50 and 29/50 in control, low-, and high-dose groups, respectively). The incidence of leukemia was similar in experimental female rats and controls. However, leukocytosis and monocytosis of the peripheral blood and bone marrow hyperplasia occurred in the experimental female rats but not in the controls. In male and female mice, the incidence of hepatocellular carcinomas and of adenomas was significantly increased in the low- and high-dose groups compared with controls and was dose-related (4/20, 32/49 and 39/47 in control, low-, and high-dose males, respectively, and 1/20, 12/50, and 24/48 in control, low- and high-dose females). It is concluded that 2,4,6-trichlorophenol induces lymphomas and leukemias in male F344 rats and induces hepatocellular carcinomas and adenomas in both sexes of B6C3F₁ mice. (21 refs)

79-6748 Transplacental and Lactational Carcinogenesis by Safrole. (Eng) Vesselinovich, S. D. (Dept. Pathology, Pritzker Sch. Medicine, Chicago, IL 60637); Rao, K. V.; Mihailovich, N. *Cancer Res* 39(11): 4378-4380; 1979.

The carcinogenicity of safrole was investigated in (C57BL/6J x C3HeB/FeJ)F₁ fetal and neonatal mice by intragastric administration of the agent to pregnant and lactating C57BL/6J females. Safrole (each treatment 120 $\mu\text{g/g}$ body wt) was administered to (a) pregnant mice (4 times on days 12, 14, 16, and 18 of gestation); (b) lactating mothers (12 times every second day following parturition); or (c) 4-wk-old offspring (180 times: 2x/wk for 90 wk). Two additional groups of offspring received a, b, and a, b, and c combination treatments. All survivors were killed at 94 wk of age. Renal epithelial tumors were observed in 7% of female offspring

exposed to safrole in utero; none of the other experimental and control animals developed these tumors. Only male offspring nursed by mothers treated with safrole developed hepatocellular tumors (34%). In contrast, direct administration of safrole, beginning at the time of weaning and continuing for the duration of the experiment, led to a significantly high incidence of hepatocellular tumors in females (48%), but not in males (8%). Of the liver tumors observed in females, 86% were hepatocellular carcinomas with a high rate of pulmonary metastases (42%). The data suggest that safrole or its metabolites came into contact with fetuses by crossing the placenta and with infants through its excretion in milk to exert the perinatal carcinogenicity. (56 refs)

79-6749 Dimethyl Terephthalate. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (121): 1-120; 1979.

The carcinogenicity of dimethyl terephthalate was assayed by feeding it at 2,500 or 5,000 ppm to B6C3F1 mice (8 wk old) and F344 rats (7 wk old) in a diet containing 2% corn oil for 103 wk. The animals (50 males and 50 females at each dose) were observed for 104-106 wk. There was no appreciable effect of terephthalate on body wt or on survival in any of the groups. In rats, tumor incidence was significantly higher in experimental groups than in control groups. In male mice, alveolar/bronchiolar adenomas or carcinomas occurred at incidences that were dose-related (1/49 controls, 8/49 low-dose, and 13/49 high-dose groups); in direct comparisons, the incidences were significantly higher in the experimental than in the control group. However, the incidence of alveolar/bronchiolar adenomas and carcinomas and their variability in three other concurrent control groups were such that it could not be concluded that the incidence of these tumors in the experimental group was related to dimethyl terephthalate administration. Twenty-seven of 49 female mice given the high dose developed malignant lymphoma, compared with 16/48 control females. However, the occurrence of lymphomas in aged female B6C3F1 mice is quite variable, and it appears unlikely that this increased incidence is related to dimethyl terephthalate administration. There was a significant negative trend in the incidence of hepatocellular carcinoma in female mice. It is concluded that dimethyl terephthalate is not carcinogenic for F344 rats or B6C3F1 mice under the conditions of this bioassay. (19 refs)

79-6750 Procarbazine. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (19): 1-124; 1979.

The carcinogenicity of procarbazine for B6C3F1 mice and Sprague-Dawley rats was studied in a 52-wk trial. The compound was administered at 6 or 12 mg/kg in mice and 15 or 30 mg/kg in rats (ip, tid). PC administration was associated with decreased mean body wt in the rats and with decreased survival in both species. Tumors involving the epithelial and neuroepithelial tissues of the nasal cavity and turbinates were observed in 21/60 male and 20/59 female rats given PC and in none of the untreated control rats. Olfactory neuroblastomas were significantly more common in PC-treated than in untreated rats. The incidence of malignant lymphomas was also significantly increased in rats given 30 mg/kg PC compared with controls, and mammary adenocarcinomas were significantly more common in PC-treated males and females than in controls. Several other neoplastic and nonneoplastic lesions were also observed in the mammary glands of male and female rats. Several types of squamous cell tumors of the ear canal and

Zymbal's gland were found in increased numbers among the PC-treated rats. Tumors of the epithelial or neuroepithelium of the olfactory bulbs and mucosa were found in 10 male and 11 female mice given 12 mg/kg PC. The incidence of olfactory neuroblastomas was significantly higher in these mice than in the controls. The incidence of leukemia was significantly higher in female mice given 6 mg/kg PC than in controls, uterine adenocarcinomas were significantly more common in PC-treated female mice than in controls, and alveolar/bronchiolar adenomas were significantly more common in PC-treated mice than in controls. Thus, procabazine is carcinogenic in both Sprague-Dawley rats and B6C3F1 mice. (21 refs)

79-6751 5-Chloro-o-toluidine. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (187): 1-44; 1979.

The carcinogenicity of 5-chloro-o-toluidine (5-chloro-2-methylbenzenamine) was tested in 6-wk-old Fischer 344 rats and B6C3F1 mice. The rats were fed diets containing 2,500 and 5,000 ppm and the mice 2,000 and 4,000 ppm 5-chloro-o-toluidine for 78 wk and were observed for an additional 26 wk. The Cochran-Armitage test indicated a significant positive association between the concentration of 5-chloro-o-toluidine given to male rats and the incidence of adrenal pheochromocytomas ($p = 0.019$), but Fisher exact statistical tests did not. In mice of both sexes, there were significant positive associations between the concentration administered and the incidence of hemangiosarcomas (1/20, 11/50, and 37/48 in the control, low-, and high-dose males, respectively, and 0/20, 6/50, and 22/43 in the control, low-, and high-dose females) and hepatocellular carcinomas (4/20, 19/50, and 25/47 in the control, low-, and high-dose males, respectively, and 0/20, 19/50, and 26/43 in the control, low-, and high-dose females). It is concluded that 5-chloro-o-toluidine is carcinogenic in male and female B6C3F1 mice, but there is no conclusive evidence for its carcinogenicity in Fischer 344 rats. (18 refs)

79-6752 o-Toluidine Hydrochloride. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (153): 1-132; 1979.

The carcinogenicity of o-toluidine hydrochloride (THC), an intermediate used in the production of textile dyes, was studied in F344 rats and B6C3F1 mice. THC was incorporated into the diet at a level of 3,000 or 6,000 ppm for 104 wk. Subchronic feeding studies were also conducted to estimate the max tolerated doses of THC. THC feeding was associated with dose-dependent decreases in body wt in both rats and mice and dose-dependent increases in mortality rate in the rats. The incidences of the following tumors were increased in THC-treated rats as compared with untreated controls: sarcomas of the spleen and other organs; mesotheliomas of the abdominal cavity or scrotum in males; transitional-cell carcinomas of the urinary bladder in females; sc tissue fibromas in males; and mammary fibroadenomas and adenomas in females. In the mice, THC induced hemangiosarcomas at various sites in the males and hepatocellular carcinomas and adenomas in the females. The findings are consistent with those previously reported. It is concluded that under the conditions of this bioassay, THC is carcinogenic in male and female F344 rats and B6C3F1 mice. (30 refs)

79-6753 Bioassay of Butylated Hydroxytoluene (BHT) for Possible Carcinogenicity. (Eng) National Cancer In-

stitute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (150): 114 pp.; 1979.

Butylated hydroxytoluene (BHT) was tested for carcinogenicity by feeding to F344 rats and B6C3F1 mice. Two dose levels (3,000 and 6,000 ppm) were fed to rats (50 of each sex at each dose) for 105 wk and to mice for 107 or 108 wk. Matched controls of 20 untreated rats and 20 untreated mice of each sex were used. No significantly increased incidence of any tumors was found in treated rats compared with the corresponding controls. In female mice of the low-dose group, the incidence of carcinomas and adenomas of the bronchiolar or alveolar regions of the female low-dose mice was higher (16/46) than in the control group (1/20; $p < 0.01$). There was no significant increase in lung tumor incidence in the high-dose group of mice (7/50). Nonneoplastic lesions that occurred with greater frequency among the treated animals were focal alveolar histiocytosis in treated female rats and various liver lesions in treated male mice. Although BHT was not carcinogenic for the animals tested, its hepatotoxicity and possible lung tumorigenicity indicate that the compound should be retested. (33 refs)

79-6754 Bioassay of Cupferron for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (100): 65 pp.; 1978.

Cupferron (N-hydroxy-N-nitroso-benzenamine) was investigated for possible carcinogenicity by adding it to the feed of Fischer 344 rats and B6C3F1 mice. Groups of 49-50 males and 50 females of each species received one of two concentrations: the time-weighted av high and low dietary concentrations were, respectively, 0.30% and 0.15% for male and female rats and 0.4% and 0.2% for male and female mice. The 78-wk dosing period was followed by an observation period of up to 28 wk for the rats and up to 18 wk for the mice. Fifty males and 50 females of each species served as controls. Dosed rats had increased incidences of hepatocellular carcinomas, squamous cell carcinomas of the forestomach, hemangiosarcomas, gliomas, ganglioneuroma and tumors of the auditory sebaceous glands, which were all thought to be compound-related. Statistical analyses indicated that cupferron administration was associated with the increased incidence of hemangiosarcomas, squamous-cell carcinomas of the forestomach, and liver neoplasms in both sexes, and possibly was associated with the increased incidence of ganglioneuromas of the adrenal gland or adrenal medulla in males and of carcinomas of the Zymbal's gland in females. In mice, cupferron was associated with hemangiomas, hepatocellular carcinomas, and Zymbal's gland carcinomas in females and adenomas of the Harderian gland and hemangiosarcomas in both sexes. Statistical analysis indicated that cupferron administration was associated with the increased incidence of hemangiosarcomas in male mice and with the increased incidence of hepatocellular carcinomas, Harderian gland adenomas, hemangiosarcomas or hemangiomas, and possibly of carcinomas of the Zymbal's gland in female mice. A critique of the bioassay of cupferron for carcinogenicity by the Data Evaluation/Risk Assessment Subgroup of the Clearinghouse on Environmental Carcinogens is presented. (22 refs)

79-6755 Bioassay of p-Cresidine for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD

20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (142): 63 pp.; 1979.

p-Cresidine was tested for possible carcinogenicity in Fisher 344 rats and B6C3F1 mice given either of two time-weighted concentrations (0.5 and 1% for rats; 0.22, 0.22, 0.46 and 0.44 for low or high dose male or female mice, respectively) in the diet for ≤ 104 wk. Mortality rates were dose-related for both sexes in both species. A higher incidence of bladder carcinomas (papillary, squamous cell, transitional cell, and undifferentiated carcinomas) and of olfactory neuroblastomas in treated rats of both sexes and of hepato/cholangiocarcinomas in male rats was observed. A higher incidence of bladder carcinomas in mice of both sexes and of hepatocellular carcinomas in female mice was observed. It is concluded that, under the conditions of the assay, p-cresidine is carcinogenic to Fischer 344 rats and B6C3F1 mice of both sexes. (19 refs)

79-6756 Release of Repetitive Nuclear RNA into the Cytoplasm in Liver of Rats Fed 3'-Methyl-4-dimethylaminoazobenzene. (Eng) Patel, N. T. (Dept. Human Biological Chemistry, Univ. Texas Medical Branch, Galveston, TX 77550); Folse, D. S.; Holubek, V. *Cancer Res* 39(11): 4460-4465; 1979.

Metabolically active 3.5S RNA bound to nonhistone chromosomal proteins, one of the low-mol-wt nuclear RNA's present in rat liver, has nucleotide sequences copied from repetitive DNA and found in the chromatin of normal rat liver. In rats fed 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB, 100 ml/kg dry food) for 1, 3, or 10 wk, approx 17% of the nucleotide sequences of this RNA was released into the cytoplasm of the liver cells as parts of larger RNA molecules. With continuous 3'-MeDAB feeding, additional sequences of this nuclear RNA were released. After 16 wk of feeding, approx 35% of the nucleotide sequences were found in the cytoplasm. No such RNA release was observed in control animals fed noncarcinogenic aminoazobenzene. The process initiated by 3'-MeDAB which leads to the appearance in the cytoplasm of these nuclear RNA nucleotide sequences was irreversible and continued even when the feeding of the azocarcinogen was interrupted after 10 wk. Toxic effects of the 3'-MeDAB in the liver cells resulted in temporary changes in the cell population of the liver. The largest changes were observed after 10 wk of feeding, when many of the hepatocytes were larger than normal and the majority of the hepatocytes had enlarged nuclei and an altered chromatin appearance. With continuous feeding of 3'-MeDAB, the changes in liver morphology characteristic for animals fed 3'-MeDAB for 10 wk became less pronounced; and the liver morphology of animals fed 3'-MeDAB for 17 wk resembled that of control animals. The release of the nucleotide sequences does not appear to be related directly to the morphological changes in the liver observed during the early stages of the feeding of 3' MeDAB. (38 refs)

79-6757 Inhibition of 3'-Methyl-4-Dimethylaminoazobenzene (3' MeDAB)-induced Hepatocarcinogenesis in the Rat: Chloramphenicol Inhibits N,N-Dimethylaniline N-Oxidase and In Vitro Binding of [³H]3' MeDAB to Protein But Not to RNA. (Eng) Labuc, G. E. (Dept. Pathology, Univ. Melbourne, Parkville Victoria, 3052, Australia); Blunck, J. M. *Biochem Pharmacol* 28(19): 3032-3034; 1979.

The effects of chloramphenicol (CAP: 2% of the diet for 4 days) on the metabolic activation of 3'-methyl-4-dimethylaminoazobenzene (MDAB: 0.06% of the diet for 4 days) and the activity of N,N-dimethylaniline (DMA) N-oxidase were studied in male Sprague-Dawley rats. Liver microsomal DMA N-oxidase activity was reduced 17.5% by CAP ($P < 0.05$). MDAB had a similar effect, and combined feeding of CAP and MDAB produced a partially additive effect (26.2% inhibition). CAP (1 mM) also inhibited DMA N-oxidase activity 19.9% in vitro ($P < 0.05$). Similar trends were observed when microsomal 3'-methyl-4-dimethylaminoazobenzene reductase, 3'-methyl-4-dimethylaminoazobenzene N-demethylase, aminopyrine N-demethylase, and 3'-methyl-4-dimethylaminoazobenzene N-demethylase activities were observed in rats pair-fed MDAB and/or CAP. Binding of MDAB metabolites to PMS protein in vitro was decreased when rats were given CAP or CAP plus MDAB, but only if 3'-phosphoadenosine-5'-phosphosulfate was included in the incubation medium. There were no changes in the activation of MDAB to metabolites that bind to yeast RNA in vitro when MDAB and/or CAP were administered. (19 refs)

79-6758 Mutational Studies with Diquat and Paraquat In Vitro. (Eng) Benigni, R. (Istituto Superiore di Sanita, Rome, Italy); Bignami, M.; Carere, A.; Conti, G.; Conti, L.; Crebelli, R.; Dogliotti, E.; Gualandi, G.; Novelletto, A.; Ortali, V. A. *Mutat Res* 68(3): 183-193; 1979.

The mutagenicities of diquat and paraquat were tested in the following assay systems: Ames test in *Salmonella typhimurium* strains TA1535, TA1537, TA1538, TA98 and TA100 with and without rat-liver microsomal fractions; resistance to 8-azaguanine in *S. typhimurium* strains hisG46, TA92, and TA1535; repair test in *S. typhimurium* strains TA1538 and TA1978; gene mutations in *Aspergillus nidulans*: 8-azaguanine (8-AG) resistance and methionine suppression (*meth* A1 locus); lethal recessive damage in *A. nidulans*; and unscheduled DNA synthesis (UDS) in human epithelial-like cells (EUE). Diquat and paraquat were positive in *S. typhimurium* (in the repair test and the 8-AG resistance system), in *A. nidulans* (for gene mutations and lethal recessive damage induction), and in EUE cells (UDS induction). (40 refs)

79-6759 Bioassay of 2-Chloro-p-Phenylenediamine Sulfate for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (113): 48 pp.; 1978.

The possible carcinogenicity of 2-chloro-p-phenylenediamine sulfate (CPS) was investigated in Fischer 344 rats and B6C3F1 mice. Groups of 50 males and 50 females of each species received one of two concentrations of CPS: in the chronic bioassay, the high and low doses for the rats were 0.3 and 0.15%, respectively, and for the mice they were 0.6 and 0.3%, respectively. The dosage period lasted for 105-107 wk in rats, 87 wk in high-dose mice, and 104-105 wk in low-dose mice. The high-dose mice were also observed for 18 wk after the dose period. Controls consisted of 20 males and 20 females of each sex. A variety of neoplasms were observed with approx equal frequency in the control and treated rats, as were a variety of degenerative, inflammatory, and proliferative lesions. With the exception of transitional-cell hyperplasia of the renal pelvis, none of the non-neoplastic lesions appeared to be related to CPS administration. It is concluded that

CPS is not carcinogenic in Fischer 344 rats. None of the statistical tests in male or female rats indicated a positive association between chemical administration and tumor incidence; however, the possibility of tumor induction in rats by CPS that could not be established under these test conditions is considered. In mice, dietary CPS administration was associated with an increased incidence of proliferative hepatocellular lesions compared with that in controls. However, no statistical evidence of the carcinogenicity of this compound was obtained for either male or female mice. (19 refs)

79-6760 Bioassay of Piperonyl Sulfoxide for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (124): 113 pp.; 1979.

The possible carcinogenicity of technical grade piperonyl sulfoxide (PS) was investigated in Fischer 344 rats and B6C3F1 mice. Groups of 50 male and 50 female rats received PS in their diet at either 1,500 or 3,000 ppm for males and either 3,000 or 6,000 ppm for females for 105 wk. Untreated rats of each sex (20) composed the control group. Groups of 50 male mice received either 350 or 700 ppm PS for 104 or 105 wk. Females initially received either 700 or 1,400 ppm, but the dose had to be reduced after wk 20 to 200 and 600 ppm, respectively, and the lower dosage period lasted for 84 or 85 wk. Matched controls consisted of 20 mice of each sex. The nature, incidence and severity of the lesions observed in dosed rats provided no clear evidence of a carcinogenic effect of PS. The incidence of hepatocellular carcinomas in male mice was associated with PS administration under the conditions of this assay; in females, the incidence of tumors could not be associated with PS administration. Thus, PS was not carcinogenic in male or female Fischer 344 rats or in female B6C3F1 mice, but was carcinogenic in male B6C3F1 mice. (23 refs)

79-6761 Triplet \leftarrow Singlet and Singlet \rightarrow Singlet Radiationless Transitions of Some Carcinogenic Compounds. (Eng) Abu-Zeid, M. E. (Physics Dept., Univ. Puerto Rico, Mayaguez, PR 00708); Perez, C.; Lopez, J. R.; Moreu, A.; Martinez, P.; Kollias, N. *J Photochemistry* 11(4): 219-226; 1979.

Radiationless transition rate parameters were determined for the following solutions: 3,4,9,10-dibenzopyrene-toluene, 20-methyl cholanthrene-benzene, 2-aminoanthracene-alcohol, and 1-aminoanthracene-alcohol. This was accomplished by measuring the fluorescence lifetimes of the compounds as a function of absolute temperature. Both monomer and excimer lifetimes were investigated. The temperature-independent part of the decay-time equation for these compounds was deemed the result of inter-system crossing or internal conversion for monomers and excimers. The temperature-dependent part was believed to be due to internal conversion, or to be of negligible value. (24 refs)

79-6762 Phthalic Anhydride. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (159): 1-107; 1979.

The carcinogenicity of phthalic anhydride was tested in 6-wk-old F344 rats and B6C3F1 mice. Male and female rats were fed the test

chemical at 7,500 or 15,000 ppm in the diet for 105 wk. Male mice received 25,000 or 50,000 ppm for 32 wk and 12,500 or 25,000 ppm for an additional 72 wk. Female mice received 25,000 or 50,000 ppm for 32 wk and then 6,250 or 12,500 ppm for 72 wk. On the basis of histological findings, there appeared to be no difference between the experimental and control rat groups with regard to frequency or distribution of neoplasms, except for malignant lymphoma in the female rats (1/20, 11/50, and 4/50 for control, low-, and high-dose females). However, due to the high and fluctuating incidence of malignant lymphoma in control F344 rats, these differences were not considered to be related to administration of the compound. In female rats, the incidence of alveolar/bronchiolar adenomas was significantly increased according to the Cochran-Armitage test ($p = 0.020$) but not to the Fischer exact test. According to both histological examination and statistical analyses, there was no increased incidence of tumors at any site in experimental male or female mice. It is concluded that phthalic anhydride is not carcinogenic in F344 rats or B6C3F1 mice of either sex. (9 refs)

79-6763 p-Quinone Dioxime. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (179): 1-50; 1979.

The carcinogenicity of p-quinone dioxime (dioxime 2,5-cyclohexadiene-1,4-dione) was tested in 6-wk-old Fischer 344 rats and B6C3F1 mice. The animals were fed the test compound in the diet for 104 wk at two dose levels: 375 ppm and 750 ppm for the rats and 750 ppm and 1,500 ppm for the mice. In rats given p-quinone dioxime, there was an increased incidence of neoplasms of the urinary tract, with bladder neoplasms occurring predominantly in females (0/16, 0/45, and 2/46 in control, low-, and high-dose males, respectively, and 0/19, 3/43, and 11/44 in control, low-, and high-dose females) and kidney tumors occurring only in males (0/20, 1/49, and 3/50 in control, low-, and high-dose groups, respectively). Statistical tests indicated a significant positive association between p-quinone dioxime administration and urinary tract tumors in female rats but not in male rats. Vascular neoplasms of the spleen were observed only in experimental mice, but the data did not give conclusive evidence of carcinogenicity at the doses administered. In female mice, there was a positive association between p-quinone dioxime administration and the incidence of hepatocellular neoplasms according to the Cochran-Armitage statistical test ($p = 0.027$) but not according to Fischer exact tests. It is concluded that dietary administration of p-quinone dioxime is carcinogenic in female Fischer 344 rats but not in male rats or B6C3F1 mice of either sex. (16 refs)

79-6764 Bioassay of Diazinon for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (137): 96 pp.; 1979.

The possible carcinogenicity of diazinon was assessed in F344 rats and B6C3F1 mice. Groups of 50 rats or mice of either sex were fed a diet containing one of two concentrations of the test chemical (400 or 800 ppm for the rats, 100 or 200 ppm for the mice) for 103 wk. Groups of 25 matched animals fed a normal diet were used as controls. Treatment had no effect on mean body wt, mortality, or tumor incidence. Some hyperactivity was observed in treated animals of both species and both sexes. It is concluded that, under the conditions of the assay, diazinon is not carcinogenic in F344 rats or B6C3F1 mice. (21 refs)

79-6765 Bioassay of Parathion for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (70): 104 pp.; 1979.

The carcinogenicity of technical grade parathion (32 or 63 ppm for male rats and 23 or 45 ppm for female rats, in the feed for 32-33 wk; and 80 or 160 ppm for mice, in the feed for 62-80 wk) was studied in Osborne-Mendel rats and B6C3F1 mice. Body wts of the male mice and high-dose male and female rats were lower than those of controls throughout the study. In the rats, there were dose-related increases in the incidence of cortical adenomas or carcinomas of the adrenal cortex. Although the incidences did not differ significantly from those in corresponding matched controls, they were higher than those in corresponding historical controls from the same laboratory. There were no significant increases in tumor incidence in the male or female mice. It was concluded that under the conditions of this bioassay, parathion is not carcinogenic for B6C3F1 mice but that it is probably carcinogenic for Osborne-Mendel rats. (19 refs)

79-6766 Bioassay of Azobenzene for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (154): 112 pp.; 1979.

Azobenzene was tested for possible carcinogenicity in F344 rats and B6C3F1 mice. Groups of 50 rats of each sex received a diet containing the test chemical at 200 or 400 ppm for 105 or 106 wk; controls consisted of 20 untreated, matched animals of each sex. Groups of 50 female mice received a diet containing the test chemical at 400 or 800 ppm for 38 wk, and, because of excessive wasting, 100 and 400 ppm for the subsequent 67 or 68 wk. Controls consisted of 20 untreated, matched mice of each sex. Mean body wt was lower in treated than in control animals and was generally dose-related. Mortality was dose-related in male rats and female mice but was not affected by treatment in female rats and male mice. Large numbers of sarcomas (fibrosarcomas, hemangiosarcomas, osteosarcomas) of the spleen and other abdominal organs were observed in rats of both sexes, and hemangiopericytomas occurred frequently in female rats; their incidence was dose-related. The incidence of tumors in mice of both sexes was not affected by treatment. It is concluded that, under the conditions of the assay, azobenzene is carcinogenic (sarcomagenic) for F344 rats but not for B6C3F1 mice. (21 refs)

79-6767 N-Glucuronidation of N-Hydroxy Aromatic Amines: A Mechanism for Their Transport and Bladder-specific Carcinogenicity. (Eng) Poupko, J. M. (Dept. Pharmacology, Univ. Miami Sch. Medicine, Miami, FL 33101); Hearn, W. L.; Radomski, J. L. *Toxicol Appl Pharmacol* 50(3): 479-484; 1979.

Glucuronide conjugates of carcinogenic N-hydroxy metabolites of the primary aromatic amines 4-aminobiphenyl (4-ABP), 2-naphthylamine (2-NA), and 1-naphthylamine (1-NA) were isolated from the urine of dogs given one of the drugs (10 mg/kg, 55 mg/kg, or 95 mg/kg po, respectively) and from the in vitro incubation of N-hydroxy metabolites with uridine-5'-diphosphoglucuronic acid-fortified dog liver microsomes. The urinary and microsomal conjugates were purified by several sequential chromatographic procedures, including Sephadex G-15, Amberlite

XAD-2, and cellulose CF-11 chromatography for microsomal conjugates and Sephadex G-10, DEAE, and Amberlite XAD-2 chromatography for urinary conjugates. The infrared spectra of purified urinary and microsomal conjugates of these three N-hydroxy aromatic amines were identical to spectra of authentic N-C glucuronides prepared by two different synthetic procedures. The urinary and microsomal conjugates comigrated with synthetic N-C glucuronides in two solvent systems. In conjunction with previous studies, these observations provide evidence that N-C glucuronidation represents the general metabolic reaction of carcinogenic N-hydroxy aromatic amines that leads to transport of these compounds to their site of action in the bladder. (18 refs)

- 79-6768 Assay for Mutagenicity of Bile in Sprague-Dawley Rats Treated Subcutaneously with Intestinal Carcinogens. (Eng) Moriya, M. (Toxicology Div., Inst. Environmental Toxicology, Suzuki-cho 2-772, Kodaira-shi, Tokyo 187, Japan); Ohta, T.; Sugiyama, F.; Miyazawa, T.; Shirasu, Y. *J Natl Cancer Inst* 63(4): 977-982; 1979.

The mode of action of sc-injected intestinal carcinogens was investigated by testing the mutagenicity of bile collected from noninbred Sprague-Dawley rats treated sc with these carcinogens in the presence and absence of β -glucuronidase. Bile samples from rats inoculated with 4-aminobiphenyl were mutagenic for *Salmonella typhimurium* TA100 only in the presence of β -glucuronidase, whereas those from 3,2'-dimethyl-4-aminobiphenyl-treated rats did not require the enzyme for mutagenicity in strain TA100. Bile from rats inoculated with 1,2-dimethylhydrazine, azoxymethane, or methylazoxymethanol acetate was not mutagenic in *S. typhimurium* strains G46 and TA100, whether β -glucuronidase was added or not; however, these carcinogens were highly mutagenic for strain G46 in the *Salmonella*-microsome mutagenicity test and/or in the host-mediated assay. (33 refs)

- 79-6769 Bioassay of 3,3'-Dimethoxybenzidine-4,4'-Diisocyanate for Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (128): 60 pp.; 1979.

A bioassay for the possible carcinogenicity of 3,3'-dimethoxybenzidine-4,4'-diisocyanate was conducted by administering the test chemical to groups of male or female F344 rats or B6C3F1 mice for 78 consecutive wk. In the rat bioassay, the test chemical was administered by gavage for the first 22 wk (3,000 or 1,500 mg/kg) and in the feed thereafter. The high and low concentrations used in the feed of both mice and rats were 44,000 and 22,000 ppm, respectively. A positive correlation between treatment and mortality was observed. Significantly increased incidences of leukemia and lymphoma in treated rats of both sexes, of skin neoplasms in treated male rats, and endometrial stromal polyps in female rats were observed. Treatment was also associated with the development of a combination of squamous cell carcinoma and sebaceous carcinoma of the Zymbal's gland and skin of the ear in rats of both sexes. It is concluded that 3,3'-dimethoxybenzidine-4,4'-diisocyanate is carcinogenic in F344 rats of both sexes, under the conditions of the assay. (18 refs)

- 79-6770 Panmyelopathy and Metastasizing Hemangioendothelioma of the Liver After Thorotrast Use. Late

Effects of Thorotrast Use in Man. (Ger) Thiel, H. (Medizinische Universitätsklinik und Poliklinik, Krankenhaus Bergmannsheil Bochum, Hunscheidtstrasse 1, D-4630 Bochum 1, W. Germany); Schott, D.; Schejbal, V.; Horster, H. G. *Med Klin* 74(40): 1451-1455; 1979.

Two patients in whom late effects of thorotrast (thorium dioxide) were diagnosed are described. A hemangioendothelioma of the liver and metastases in the lungs and thyroid were found during autopsy of a 61-yr-old man who had undergone thorotrast femoral angiography 36 yr previously. Thorotrast deposits in his liver, spleen, and abdominal lymph nodes were found during screening for thorotrast damage 7 yr before his final illness. The results of whole-body counting suggested that the thorotrast dose was approx 80 ml. At autopsy, thorotrast deposits were found, next to the liver tumor, in the portal circulation, and especially in the fibrous, calcified, 40-g spleen. An aplastic blood syndrome was diagnosed in a 56-yr-old patient who had been given thorotrast (estimated dose, 17 ml) 34 yr previously for carotid angiography. Thorotrast deposits were found in the liver, spleen, and bone marrow. Thorotrast was used in diagnosis until 1956. Regular follow-up at 1- to 2-yr intervals of persons previously given thorotrast is recommended. (31 refs)

- 79-6771 Histopathological Changes Induced in the Urinary Bladder and Liver of Female BALB/c Mice Treated Simultaneously with 2-Naphthylamine and Cyclophosphamide. (Eng) Yoshida, M. (Second Dept. Pathology, Sch. Medicine, Tokushima Univ., Kuramoto-cho 3-chome, Tokushima 770, Japan); Numoto, S.; Otsuka, H. *Gann* 70(5): 645-652; 1979.

The effect of 2-naphthylamine and cyclophosphamide on the urinary bladder and liver of female BALB/c mice was investigated. The bladder mucosa of mice treated with 2-naphthylamine alone (2,000 ppm in the diet) for 40 wk showed diffuse hyperplasia. Administration of 2-naphthylamine for 40 wk plus injections of cyclophosphamide (200 mg/kg body wt) produced bladder carcinomas, associated with downward growth of the bladder epithelium in approx 30.8-35.7% of the animals. All the bladder carcinomas were of the transitional cell type and most of them contained pseudoglandular areas. There was a higher incidence of hepatomas in mice treated with 2-naphthylamine plus cyclophosphamide than in mice treated with 2-naphthylamine alone. Most of the hepatomas were solitary and showed a trabecular pattern. Cyclophosphamide seemed to have a promoting effect on carcinogenesis of the bladder mucosa and liver induced by 2-naphthylamine in female BALB/c mice. (19 refs)

- 79-6772 Bioassay of 1,5-Naphthalenediamine for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (143): 59 pp.; 1978.

A bioassay of 1,5-naphthalenediamine for possible carcinogenicity was conducted by feeding groups of 50 F344 rats or B6C3F1 mice of each sex a diet containing the test chemical at either of two concentrations (0.1% and 0.05% for rats; 0.2% and 0.1% for mice) for 103 wk. Groups of 50 mice and 25 rats of each sex fed a normal diet were used as controls. No correlation between treatment and mortality was observed. A significantly increased incidence of endometrial stromal polyps (sometimes undergoing transformation to endometrial stromal sarcomas) and of either adenomas or carcinomas of the clitoral gland was observed in female rats. An in-

CHEMICAL CARCINOGENESIS

creased incidence of thyroid neoplasms was observed in mice of both sexes (papillary carcinomas, follicular-cell adenomas, and papillary cystadenomas in both sexes; C-cell carcinomas in females). A significant increase of hepatocellular carcinomas and alveolar/bronchial adenomas was observed in female mice. It is concluded that, under the conditions of the assay, 1,5-naphthalenediamine is carcinogenic in female F344 rats and B6C3F1 mice of both sexes. (8 refs)

79-6773 Long-Term Toxicologic Studies of 2,3,7,8-Tetrachlorodibenzo-*p*-dioxin (TCDD) in Laboratory Animals. (Eng) Kociba, R. J. (Toxicology Res. Lab., Health and Environmental Res., Dow Chemical Co., Midland, MI 48640). Keyes, D. G.; Beyer, J. E.; Carreon, R. M.; Gehring, P. J. *Ann NY Acad Sci* 320:397-404; 1979.

The chronic toxicity and carcinogenicity of 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD: 0.001-0.1 µg/kg/day in the diet for 2 yr) were studied in male and female Sprague-Dawley rats. The highest dose level caused multiple toxicologic effects. Liver toxicity was consistently observed, and this was accompanied by morphologic changes in the lymphoid, respiratory, and vascular tissues. There was an increased incidence of hepatocellular carcinoma and squamous cell carcinoma of the lung, hard palate/nasal turbinates, and tongue at this dose level. However, the incidences of pituitary, uterine, mammary gland, pancreatic, and adrenal medullary tumors were decreased at this dose level. The incidences of other spontaneous lesions such as chronic renal disease were also decreased. A lesser degree of toxicity, primarily of the liver, was seen in animals given 0.01 µg/kg/day TCDD, but the incidence of neoplasms was not increased at this dose level. No adverse effects were seen in rats given 0.001 µg/kg/day TCDD, although the liver and fat contained 540 ppt TCDD at the termination of the study. (8 refs)

79-6774 2,7-Dichlorodibenzo-*p*-dioxin. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (123): 1-103; 1979.

The carcinogenicity of 2,7-dichlorodibenzo-*p*-dioxin (DCDD) which is found as a by-product in the manufacture of pentachlorophenol and in the herbicide 2,4,5-trichlorophenoxyacetic acid and its esters, was studied in B6C3F1 mice and Osborne-Mendel rats. DCDD was incorporated in the diet at 5,000 or 10,000 ppm for 110 wk. Survival was not decreased in DCDD-treated animals, and tumor incidence was not significantly increased in DCDD-treated rats or female mice. Although the incidence of hepatocellular tumors increased with increasing dose in male mice, the significance of this finding was questioned based on past experience in this laboratory. There were significant increases in the incidences of leukemias or lymphomas ($p = 0.006$) and hemangiomas or hemangiosarcomas ($p = 0.028$) in male mice given the high DCDD dose compared with low-dose and control groups, but the incidences of these tumors showed no increase with increasing dose, and the findings were of questionable significance. It is concluded that under the conditions of this bioassay, DCDD is not carcinogenic in Osborne-Mendel rats or female B6C3F1 mice but that it may be carcinogenic in male B6C3F1 mice. (20 refs)

79-6775 Dibutyltin Diacetate. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (183): 45 pp.; 1979.

The carcinogenicity of dibutyltin diacetate (DBDA: 62.5-250 ppm in the diet for 26 wk) for Fischer 344 rats and B6C3F1 mice was studied. Subchronic toxicity tests with DBDA were also conducted in the same strains. Mortality increased in a dose-dependent fashion in DBDA-treated male rats and female mice, and mean body wt was decreased in male mice. Tumor incidence was not significantly increased in DBDA-treated rats or male mice relative to untreated controls. However, there was an increase in uterine neoplasms among DBDA-treated female rats and this, coupled with the fact that many tissues from the female rats were lost prior to microscopic examination, was taken as an indication that DBDA may be carcinogenic in these animals. The incidence of hepatocellular adenomas increased with DBDA dose in the female mice, but these data were not significant. Thus, there is no conclusive evidence that DBDA is carcinogenic in male Fischer 344 rats or male or female B6C3F1 mice. (15 refs)

79-6776 Mutagenicity of Pyrrolizidine Alkaloids in the Salmonella/Mammalian-Microsome Test. (Eng) Yamanaka, H. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Nagao, M.; Sugimura, T.; Furuya, T.; Shirai, A.; Matsushima, T. *Mutat Res* 68(3): 211-216; 1979.

The mutagenicities of B pyrrolizidine alkaloids were studied. Clivorine, fukinotoxin, nelioetrine, lasiocarpine, ligularidine, LX201, and senkirkine, were mutagenic in the Ames's test (*Salmonella typhimurium* strain TA100). Preincubation of these alkaloids with S9 mix and bacteria in a liquid medium was essential for the demonstration of their mutagenicities. (24 refs)

79-6777 Bioassay of Azinphosmethyl for Possible Carcinogenicity. (Eng) National Cancer Institute (Carcinogenesis Testing Program, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (69): 126 pp.; 1979.

The carcinogenicity of technical grade azinphosmethyl (APM, 78 or 156 ppm for male rats, 62.5 or 125 ppm for female rats, 31.3 or 62.5 ppm for male mice, and 62.5 or 125 ppm for female mice, incorporated in the feed for 80 wk) for Osborne-Mendel rats and B6C3F1 mice was studied. Body wts of male rats and mice and high-dose female rats and mice were lower than those of controls throughout the study, and typical signs of organophosphate poisoning were observed in some animals. Many tumors of the endocrine organs were observed in the rats, but the incidences in most cases were not significantly higher than in the matched controls. However, the incidence of tumors of the pancreatic islets and the follicular cells of the thyroid in the male rats suggested that APM is a carcinogen in these animals. There was no increase in tumor incidence in the mice that could be attributed to APM feeding. Thus, under the conditions of this bioassay, APM was not carcinogenic for male or female B6C3F1 mice or female Osborne-Mendel rats. (18 refs)

79-6778 3-Sulfolene. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (102): 1-46; 1979.

The carcinogenicity of 3-sulfolene (an intermediate in the production of petroleum, plastics, and textiles) was studied in Osborne-

Mendel rats and B6C3F1 mice. 3-Sulfolene (200-560 mg/kg for rats and 100-300 mg/kg for mice) was given by gavage 5 days/wk over 15 4-wk periods, each treatment period being preceded by a week in which no drug was given. Subchronic toxicity tests were conducted to determine max tolerated dosages. Although 3-sulfolene caused dose-dependent increases in mortality rate among both rats and mice, most animals lived long enough to be at risk for late-developing tumors. Accelerated mortality was associated with toxicity to the circulatory, urinary, biliary, and reproductive systems. There were dose-dependent increases in the incidence of hepatocellular carcinoma in 3-sulfolene-treated male mice compared with untreated controls, but the increases were not statistically significant. There were no other positive associations between 3-sulfolene treatment and tumor incidence. It is concluded that under the conditions of this bioassay, 3-sulfolene is not carcinogenic for Osborne-Mendel rats or for B6C3F1 mice. (15 refs)

- 79-6779 Induction of Hepatic Neoplastic Lesions in Mice With a Single Dose of Hycanthone Methanesulfonate After Partial Hepatectomy. (Eng) Tsuda, H. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA 19140); Sarma, D. S.; Rajalakshmi, S.; Zubroff, J.; Farber, E.; Batzinger, R. P.; Cha, Y. N.; Bueding, E. *Cancer Res* 39(11): 4491-4496; 1979.

Experiments were designed to determine whether hycanthone methanesulfonate [1-((2-(diethylamino)ethyl) amino)-4-(hydroxymethyl)thioxanthene-9-one monomethanesulfonate], an antischistosomal drug, and its analog, IA-4-N-oxide [8-chloro-2-(2-(diethylamino)ethyl)-2H-[1]benzothioapyrano[4,3,2-cd]indazole 5-methanol monomethanesulfonate], will induce neoplastic lesions in the liver of mice not infected with *Schistosoma mansoni*. All the mice received a single im injection of hycanthone methanesulfonate (76 mg/kg), IA-4-N-oxide (80 mg/kg), or an equivalent dose of the solvent, 0.9% NaCl soln, 42 hr after partial hepatectomy. Of the mice receiving hycanthone methanesulfonate and living 200 days or longer, 11.5% had hepatocellular carcinoma and 4.2% had liver sarcoma. These malignant neoplasms were not seen in the animals receiving either IA-4-N-oxide or 0.9% NaCl solution. In addition, mice receiving hycanthone methanesulfonate showed a significantly higher incidence of both type 1 (43% compared to 21% in controls) and type 2 (21% compared to 12% in controls) hepatocyte neoplasms. Mice receiving IA-4-oxide showed no increased incidence of neoplasms. (30 refs)

- 79-6780 Bioassay of Aldicarb for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (136): 106 pp.; 1979.

A bioassay of aldicarb for possible carcinogenicity was conducted in F344 rats and B6C3F1 mice. Groups of 50 rats or mice of each sex received the test chemical in feed at either 2 or 6 ppm for 103 wk. Groups of 25 animals were used as matched controls. No significant difference in mean body wt between treated or control animals was observed, and treatment did not affect survival. Hyperactivity was observed in treated mice. No correlation between treatment and the incidence of tumors was observed. It is concluded that, under the conditions of the test, aldicarb is not carcinogenic in F344 rats or B6C3F1 mice of either sex. (29 refs)

- 79-6781 Investigation into the Mutagenic Activity of Azathioprine (Imuran) in Different Test Systems.

(Eng) van Went, G. F. (Lab. Pharmacology, Natl. Inst. Public Health, P.O. Box 1, 3720 BA Bilthoven, Netherlands). *Mutat Res* 68(2): 153-162; 1979.

Chromosome damage induced by azathioprine (Imuran) was investigated in the micronucleus test with mice and rats, in the pertussis-stimulated lymphocyte metaphase test with rabbits, and in children on azathioprine therapy. In the micronucleus test, there was a dose-dependent increase in the number of cells with micronuclei. Doses given ip twice in 24 hr were 25, 50 and 100 mg/kg body wt for mice and 50, 100 and 200 mg/kg for rats. In the lymphocyte test, a dose of either 5 or 20 mg/kg body wt was given po to rabbits on three successive days after pertussis injection. These treatments induced a significantly increased number of cells with chromosomal abnormalities as compared with controls. These results were confirmed by observations of increased numbers of structural chromosome abnormalities in lymphocyte cultures of children on long-term azathioprine therapy. (42 refs)

- 79-6782 Carcinomas of the Liver in Rats Ingesting Kepone. (Eng) Reuber, M. D. (Frederick Cancer Res. Center, Frederick, MD 21701). *Neoplasma* 26(2): 231-235; 1979.

Young male and female albino rats ingested 0, 1, 5, 10 or 25 ppm decachloroocta-hydro-1,3,4-methano-2H-cyclobuta(d) pentalen-2-one (Kepone), an organochlorine pesticide, in the diet for 2 yr. Carcinomas of the liver, as well as hyperplastic nodules and moderate and severe diffuse hyperplasia, were observed in Kepone-treated rats, but not in controls. Female rats ingesting Kepone were more susceptible than male rats to hepatic carcinogenesis. Rats ingesting 50 or 80 ppm Kepone developed severe diffuse hepatic hyperplasia and did not survive beyond 26 wk. (28 refs)

- 79-6783 Cytogenetic Effect of Methotrexate on Human Cells In Vivo. Comparison Between Results Obtained by Chromosome Studies on Bone-Marrow Cells and Blood Lymphocytes and by the Micronucleus Test. (Eng) Jensen, M. K. (Section Hematology, Dept. Medicine B, Aalborg Hosp., 9100 Aalborg, Denmark); Nyfors, A. *Mutat Res* 64(5): 339-343; 1979.

The mutagenic effect of methotrexate (MTX: 25-50 mg, im or po) on the cells of 22 patients was studied via chromosome studies on bone-marrow cells and blood lymphocytes and via the micronucleus test. Examination of bone-marrow aspirates from 18 MTX-treated patients demonstrated structural aberrations in 0%-10% of metaphases (mean, 4.0%), compared with 0%-4% of metaphases (mean, 1.4%) in 10 control bone marrow preparations ($p < 0.005$). The aberrations were mainly breaks of the chromatid and chromosomal types. Structural aberrations (chromatid breaks) were observed in 0%-2% of metaphases (mean, 0.5%) in the lymphocyte cultures of seven MTX-treated patients studied, compared with 2% of the metaphases of control cultures. Micronuclei were present in 0%-32% of the erythroblasts from 10 MTX-treated patients (mean, 12.0%), compared with 0%-4% (mean 0.68%) of the erythroblasts from control subjects ($p < 0.0005$). No erythroblasts with micronuclei were seen in three patients with psoriasis who had not received MTX. The data indicate that future studies of the possible cytogenetic effects of chemical agents must include examinations of bone marrow cells and suggest that the micronucleus test may be more sensitive in detecting mutagenic effects than chromosome studies. (17 refs)

- 79-6784 Mutagenic and Colicine-inducing Activity of Two Antioxidants: Pyrogallol and Purpurogallin. (Eng) Ben-Gurion, R. (Israel Inst. Biological Res., Ness-Ziona, Israel). *Mutat Res* 68(3): 201-205; 1979.

The antioxidant pyrogallol (PYL) and its oxidative derivative purpurogallin (PUL) were tested for ability to induce colicine and for mutagenicity in the Ames test. Both substances induced colicine E2 when tested directly on test plates; the most effective dose for PYL was 200 µg/plate and for PUL, was 100 µg/plate in the presence of a liver microsomal preparation. The mutagenicity of PUL and PYL was tested with the TA1537 and TA100 strains of *Salmonella typhimurium*. PYL was mutagenic in these strains at doses of 20-200 µg/plate; its mutagenicity was reduced in the presence of a rat liver microsomal preparation. PUL was only weakly mutagenic in these two strains, even at doses (300-600 µg/plate) much higher than those needed to induce colicine. In an attempt to overcome the problem produced by the long exposure to PUL on the test plates, the bacteria were exposed to PUL in nutrient broth for shorter periods of time and diluted on test plates; viable bacteria were counted, and the number of mutants/survivor was calculated. The results revealed that PUL was highly mutagenic for exposure times of up to 4 hr. When the mutants grown on the PUL plates were mixed with the original tester strain and the growing mixture tested for sensitivity towards the killing effects of PUL, it was found that the mutants in the mixture were as sensitive to cell killing as the parent strain. It was concluded that PYL and the food additive PUL represent potential health hazards with regard to mutagenesis and carcinogenesis. (7 refs)

- 79-6785 Mutagenicity Tests with Griseofulvin. (Eng) Leonard, A. (Mammalian Genetics Lab., Dept. Radiobiology, C.E.N.-S.C.K., B 2400 Mol, Belgium); Poncelet, F.; Grutman, G.; Carbonelle, E.; Fabry, L. *Mutat Res* 68(3): 225-234; 1979.

The clastogenic properties of griseofulvin were studied in male BALB/c mice given the drug ip (0.5-2.0 g/kg); the genetic effects in *Salmonella typhimurium* were also investigated. In mice, bone marrow cells were examined for micronucleated RBC and chromosomal aberrations, and pre- and postmeiotic cells were examined for reciprocal translocations or dominant lethal mutations, respectively. In *S. typhimurium*, the induction of his⁺ revertants was studied. All tests for mutagenicity were negative with griseofulvin, whereas highly significant effects were obtained in positive control assays with thio-TEPA [tris(1-aziridinyl)phosphine sulfide; 1.25-20 mg/kg, ip]. (35 refs)

- 79-6786 Inhibition of DNA Synthesis in Cultured Lymphocytes and Tumor Cells by Extracts of Betel Nut, Tobacco, and Miang Leaf, Plant Substances Associated with Cancer of the Ororespiratory Epithelium. (Eng) Yang, J. A. (Dept. Surgery, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Huber, S. A.; Lucas, Z. J. *Cancer Res* 39(12): 4802-4809; 1979.

The high incidence of oropharyngeal, esophageal, and laryngeal cancers in certain parts of the world has been attributed to conjugated tannins found in certain folk medicinal herbs. Miang leaf and betel nut extracts prepared with phosphate-buffered saline inhibited [³H]thymidine incorporation by phytohemagglutinin-stimulated human lymphocytes and by rat mammary tumor and mouse L-cells in logarithmic growth. Pretreating the lymphocytes for 1 or 4 hr with the extracts inhibited phytohemagglutinin-

induced thymidine incorporation 72 hr later. At concentrations of 2.5 volumes % or lower, miang and betel nut extracts inhibited thymidine incorporation 40%-98% without any apparent signs of toxicity as demonstrated by the ⁸⁶Rb equilibrium assay. Neither extract inhibited cytotoxicity of rat mammary tumor cells by immune syngeneic spleen cells. The inhibitory factors had mol wts between 1,000 and 10,000 daltons as determined by ultrafiltration and were unaffected by boiling for 3 min or by treatment with alcohol; therefore they are probably not proteins. This in vitro demonstration of inhibition of DNA synthesis by these plant extracts presumably enriched for conjugated tannins may relate to inhibition of growth of rats and chickens fed conjugated tannin-contaminated sorghum feed. The carcinogenic potential of either these extracts or conjugated tannins is not yet established. (33 refs)

- 79-6787 Inhibition of Aflatoxin-induced Serum α -Fetoprotein in Rats Fed Cauliflower. (Eng) Boyd, J. N. (Dept. Food Science and Technology, Inst. Food Science, New York State Agricultural Experiment Station, Cornell Univ., Geneva, NY 14456); Sell, S.; Stoewsand, G. S. *Proc Soc Exp Biol Med* 161(4): 473-475; 1979.

The effect of aflatoxin B₁ (AB: 1 ppm in diet for 5 wk) and cauliflower (added to the diet for 5 wk) on serum α -fetoprotein (AFP) levels was studied in male Fischer 344 Sch, rats. Serum AFP levels were similar in rats fed control and cauliflower-containing diets. AB significantly increased serum AFP levels, which had been reduced by cauliflower consumption; AFP levels in animals fed AB plus cauliflower were similar to those in rats fed the control diets. Cauliflower enhanced hepatic aminopyrine N-demethylase activity, and this activity was not altered by AB treatment. Hepatic mixed function oxidase activity was not significantly altered by AB feeding. The results suggest that the reduced serum AFP levels in rats given AB plus cauliflower are indicative of the ability of dietary cauliflower to protect against AB-induced hepatocarcinoma. (22 refs)

- 79-6788 In Vitro Effects of Aflatoxin B₁ on the Uptake of ¹⁴C-orotic Acid Into Kidney, Liver and Muscle Tissue of the Mongolian Gerbil, *Meriones unguiculatus*. (Eng) Kinzie, J. M. (Dept. Biology, Virginia Commonwealth Univ., Richmond, VA 23284); Llewellyn, G. C. *Bull Environ Contam Toxicol* 23(4/5): 491-496; 1979.

The effects of aflatoxin B₁ (AFB) on the uptake of ¹⁴C-orotic acid (OA) into kidney, liver, and muscle tissue of the Mongolian gerbil (*Meriones unguiculatus*) in vitro were studied. In tissues treated with 1.25 µg/ml AFB, there was no clear effect on OA uptake by kidney or muscle, although hepatic uptake appeared to be depressed, especially in the male. At 2.50 µg/ml, OA uptake was clearly depressed in all tissues from female gerbils, but the results were ambiguous and insignificant in male tissues. The overall sensitivity of the tissues to AFB appeared to be: liver > muscle > kidney. (13 refs)

- 79-6789 Production and Characterization of Antibody Against Aflatoxin M₁. (Eng) Harder, W. O. (Dept. Food Microbiology and Toxicology, Univ. Wisconsin, Madison, WI 53706); Chu, F. S. *Experientia* 35(8): 1104-1107; 1979.

Antibody against aflatoxin M₁ was obtained after immunization of rabbits with bovine serum albumin-aflatoxin M₁ oxime conjugate. The antibody had greatest binding efficiency for aflatoxin M₁ and was less efficient for aflatoxin B₁. Cross-reaction of antibody with aflatoxin Q₁, aflatoxicol, and aflatoxin B₂ was weak. Aflatoxin B₂, aflatoxin G₁, aflatoxin G₂, and aflatoxin B₁-guanine adduct showed almost no cross-reaction with the antibody. The sensitivity of the binding assay for aflatoxin M₁ detection was in the range of 1-10 ng per assay. Detailed methods for the preparation of the conjugate, production of immune serum, and methods for antibody determination are described. (24 refs)

- 79-6790 Induction of Osteogenic Sarcomas and Tumors of the Hepatobiliary System in Nonhuman Primates with Aflatoxin B₁. (Eng) Sieber, S. M. (Lab. Chemical Pharmacology, NCI, Bethesda, MD 20205); Correa, P.; Dalgard, D. W.; Adamson, R. H. *Cancer Res* 39(11): 4545-4554; 1979.

Ongoing studies on the carcinogenicity of aflatoxin B₁ (AFB₁) in nonhuman primates are updated. A total of 47 Old World monkeys, chiefly rhesus and cynomolgus, received AFB₁ ip (0.125-0.25 mg/kg) and/or po (0.1-0.8 mg/kg) for 2 mo or longer, and 12 are currently alive and without evidence of tumor. Of the 35 monkeys necropsied to date, 13 (37%) developed one or more malignant neoplasms, yielding an overall tumor incidence of 28%. Five of the neoplasms were primary liver tumors (2 hepatocellular carcinomas and 3 hemangioendothelial sarcomas), and 2 cases of osteogenic sarcoma were found. Other tumors diagnosed were 6 carcinomas of the gallbladder or bile duct, 3 tumors of the pancreas or its ducts, and one papillary Grade 1 carcinoma of the urinary bladder. The tumors developed in animals receiving an average total AFB₁ dose of 709 mg (range, 99-1,354 mg) for an average of 114 mo (range, 47-147 mo). Of the 22 necropsied monkeys without tumor, 15 (68%) showed histological evidence of liver damage, including toxic hepatitis, cirrhosis, and hyperplastic liver nodules. These animals had received an average total AFB₁ dose of 363 mg (range, 0.35-1,368 mg) for an average of 55 mo (range, 2-141 mo). The results indicate that AFB₁ is a potent hepatotoxin and carcinogen in nonhuman primates and further support the hypothesis that humans exposed to this substance may be at risk of developing cancer. (33 refs)

- 79-6791 The Effect of Amaranth on the Rapid Onset of Liver Cancer Induced by Aflatoxin B₁. (Eng) Nizami, H. M. (Pakistan Medical Res. Council, Res. Center JPMC, Karachi, Pakistan); Nizami, F.; Zuberi, S. J. *Lav Ist Anat Istol Patol Perugia* 38(3): 87-90; 1978.

The cocarcinogenic activity of amaranth dye (15 mg/wk for 10 wk, by gastric intubation), which has anti-vitamin A activity in the liver, on the early onset of liver cancer induced by aflatoxin B₁ (AFB₁: 15 mg/kg for 10 wk, by gastric intubation) was studied in male JPMC rats. Weight gain was depressed in rats that received amaranth alone, compared with that in untreated controls. Weight loss was also observed in rats given amaranth plus AFB₁, and liver tumors and hemorrhagic areas were found. Death in these animals occurred during the 9th and 11th wk of treatment. Similar liver tumors were found in animals given AFB₁ only, but these mice did not die until the 15th wk. The wet weights of the livers of animals given AFB₁ plus amaranth were less than those of the livers of animals given AFB₁ alone. Agents like amaranth lower body resistance and may act as cocarcinogens in promoting earlier carcinogenesis and mortality. (5 refs)

- 79-6792 1-Amino-2-methylantraquinone. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (111): 1-68; 1979.

The carcinogenicity of 1-amino-2-methylantraquinone (AMAQ), an intermediate in the synthesis of anthraquinone dyes and a dye itself, in Fischer 344 rats and B6C3F₁ mice was studied. AMAQ was added to the rats' diet at 0.06% or 0.03% for 17 wk and 0.24% or 0.12% for an additional 62 wk. In mice, the dose was 0.06% for 78 wk or 0.03% for 16 wk, 0.12% for an additional 26 wk, and 0.03% for 31 wk thereafter. Subchronic feeding studies were also conducted. In the chronic study, the incidences of hepatocellular carcinoma and neoplastic liver nodules increased significantly with AMAQ dosage in treated rats, and the frequency of tubular cell adenomas and renal adenocarcinomas increased with increasing dosage in AMAQ-treated male rats. Although the incidence of pituitary adenomas was also significantly increased in AMAQ-treated male rats, the validity of these results was questioned based on past experience in this laboratory. The incidence of liver tumors in female mice that received AMAQ was significantly higher than that in control female mice, but there were no other significant associations between tumor incidence and drug treatment in this species. AMAQ was nephrotoxic to male mice, and kidney adenocarcinomas were found in two of these animals. It is concluded that AMAQ is carcinogenic for male and female Fischer 344 rats and female B6C3F₁ mice under the conditions of this study. (22 refs)

- 79-6793 Ornithine Decarboxylase Activity and DNA Synthesis After Treatment of Cells in Culture with 12-O-Tetradecanoylphorbol-13-acetate. (Eng) O'Brien, T. G. (Wistar Inst. Anatomy and Biology, Philadelphia, PA 19104); Lewis, M. A.; Diamond, L. *Cancer Res* 39(11): 4477-4480; 1979.

The ability of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) to induce the enzyme ornithine decarboxylase (ODC) and to stimulate DNA synthesis was studied in four different cell types in vitro. The effects of this agent on each cell type differed as follows: (a) in hamster embryo cells, TPA induced ODC but had no effect on DNA synthesis; (b) TPA induced ODC and stimulated DNA synthesis in BALB/c 3T3 mouse cells; (c) TPA did not induce ODC in human fibroblasts but did stimulate DNA synthesis; and (d) TPA induced neither ODC nor DNA synthesis in rat embryo fibroblasts. In contrast, ODC was induced and DNA synthesis was stimulated in all cell types by fresh serum-containing medium. Treatment of the cells with a combination of fresh medium and TPA resulted in an approximate summation of the effects of treatment with each agent alone. These results emphasize the differences in the response of various cells to TPA. They also show that at least in some cells the induction of ODC and stimulation of DNA synthesis following TPA treatment can be regulated independently. (21 refs)

- 79-6794 Regulation of Normal Differentiation in Mouse and Human Myeloid Leukemic Cells by Phorbol Esters and the Mechanism of Tumor Promotion. (Eng) Lotem, J. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Sachs, L. *Proc Natl Acad Sci USA* 76(10): 5158-5162; 1979.

In one clone of mouse myeloid leukemic cells (MG1'D* clone 7-M18), 12-O-tetradecanoylphorbol-13-acetate (TPA: 1 µg/ml) induced normal cell differentiation by inducing the production of MG1 (normal protein inducer of differentiation to macrophages or

granulocytes) activity. TPA induced rosettes (mainly Fc), immune phagocytosis (Fc and C3), lysozyme, and morphological differentiation. Other MGI⁺D⁺ or MGI⁺D⁻ clones were not induced to differentiate by TPA. In an MGI⁺D⁻ clone, TPA induced cell susceptibility to externally added MGI but not to lipopolysaccharide or dexamethasone. TPA also induced differentiation in a human myeloid leukemic cell line (HL-60), with the induction of MGI activity and enhanced susceptibility to added MGI. The seeding of normal mouse bone marrow cells with TPA resulted in cluster formation due to the induction of MGI activity. When added together with MGI, TPA increased the number of macrophage and granulocyte colonies and clusters in the marrow cells. The use of different phorbol esters showed that this enhancing effect on MGI activity paralleled tumor-promoting ability. The activity of MGI was not replaced by epidermal or fibroblast growth factor (0.1-1 $\mu\text{g/ml}$) or dexamethasone (0.4 $\mu\text{g/ml}$). The results indicate that a tumor promoter such as TPA can induce the production of and increase cell susceptibility to a normal regulator of cell multiplication and differentiation. Clonal differences in the response to TPA may explain differences in tumor-promoting activity in different tissues and genetically different animals. (38 refs)

- 79-6795 Collagenase Production by Synovial Fibroblasts Treated with Phorbol Myristate Acetate. (Eng) Brinkerhoff, C. E. (Dept. Medicine, Connective Tissue Disease Section, Dartmouth Medical Sch., Hanover, NH 03755); McMillan, R. M.; Fahey, J. V.; Harris, E. D. *Arthritis Rheum* 22(10): 1109-1116; 1979.

Rabbit synovial fibroblasts were treated with the tumor promoter phorbol myristate acetate (PMA: 0.01 $\mu\text{g/ml}$), and a series of resultant intracellular events were measured. Ten min after the addition of PMA, there was a temporary increase in the intracellular cyclic AMP level, followed by a transient decrease in ³H-thymidine incorporation into DNA. After 24 hr, the prostaglandin E₂ level was increased (from approx 20 ng/mg cell protein prior to 24 hr to 500 ng). Negligible amounts of collagenase were released into the medium during the first 24 hr of PMA exposure, but there was a sudden increase after 42-48 hr; the amount was sufficient to degrade more than 250 μg collagen fibril/hr/mg cell protein at 37 C. Aspirin or indomethacin treatment (10^{-4} - 10^{-6} M for aspirin and 10^{-6} - 10^{-8} M for indomethacin) abolished prostaglandin E₂ production but did not affect the collagenase levels. Enzyme production was associated with cessation of cell proliferation, measured by protein content/culture and cell number. A long lag period between PMA treatment and the appearance of collagenase in the culture medium suggests that this system may be useful for detailed studies concerning the intracellular events leading to the induction of collagenase production by these cells. (36 refs)

- 79-6796 Enhancing Effect of Phorbol Esters on Induction of Differentiation of Mouse Myeloid Leukemia Cells by Human Urinary Protein and Lipopolysaccharide. (Eng) Nakayasu, M. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Shoji, M.; Aoki, N.; Sato, S.; Miwa, M.; Sugimura, T. *Cancer Res* 39(11): 4668-4672; 1979.

12-O-Tetradecanoylphorbol-13-acetate (TPA), a potent tumor promoter in mouse skin, enhanced differentiation of cultured mouse myeloid leukemia cells (M1) induced by human urinary protein or by lipopolysaccharide from *Salmonella typhosa*. TPA (in varying concentrations) enhanced differentiation of all the markers tested, such as phagocytosis, Fc rosette formation,

lysozyme activity, and morphological alteration. Other potent tumor-promoting macrocyclic plant diterpenes also enhanced the induction of differentiation, but non-tumor-promoting diterpenes did not. These findings were in marked contrast with generally accepted findings on the inhibitory effect of 12-O-tetradecanoylphorbol-13-acetate on terminal differentiation observed in other cell culture systems, but were consistent with results observed in certain leukemia cells. - 79-6797 Tumor Promoters Induce Changes in the Chick Embryo Fibroblast Cytoskeleton. (Eng) Rifkin, D. B. (Dept. Cell Biology, New York Univ. Medical Center, New York, NY 10016); Crowe, R. M.; Pollack, R. *Cell* 18(2): 361-368; 1979.

The effect of the tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) on the actin-containing elements of the cytoskeleton of chick embryo fibroblasts (CEF) was examined. TPA at concentrations as low as 7.3×10^{-10} M induced a reversible change in the cytoskeleton, as visualized by indirect immunofluorescence using anti-actin antibodies. Cells incubated with TPA lost the ordered actin-containing structures found in normal cells and resembled Rous sarcoma virus-transformed cells in that the immunofluorescent actin pattern was diffuse. The TPA effects were both dose- and time-dependent. TPA analogs that are inactive as tumor promoters did not induce cytoskeletal changes at the concentrations tested, while a second tumor promoter, PDD, did cause alterations in actin-containing structures. The action of TPA required de novo synthesis of both RNA and protein. The direct cytoskeletal changes were neither plasmin-dependent nor subject to inhibition by incubating the cells with high levels of protease inhibitors during the exposure to TPA. However, plasminogen did increase the sensitivity of cells to TPA. (63 refs)

- 79-6798 Epidermal Prostaglandins After Topical Application of a Tumor Promotor. (Eng) Bresnick, E. (Vermont Regional Cancer Center, Univ. Vermont Coll. Medicine, Burlington, VT 05401); Meunier, P.; Lamden, M. *Cancer Lett* 7(2/3): 121-125; 1979.

12-O-Tetradecanoyl-13-acetate (TPA: 10 μg in acetone) was applied to the shaved backs of CD-1 mice to determine the effect of topical treatment on epidermal prostaglandins. The mice were killed 1-48 hr later, and epidermal prostaglandins were analyzed by radioimmunoassay. The prostaglandin E₂ (PGE₂) level was elevated almost 10-fold at 24 hr after a single application of TPA compared with control levels (2.20 vs 0.23 ng PGE₂/ μg DNA). At 12 and 48 hr after application, the epidermal PGE₂ concentration was 1.50 ng/ μg DNA. Prostaglandin F_{2 α} (PGF_{2 α}) was also significantly elevated over control values by 12 hr (0.19 vs 0.06 ng PGF_{2 α} / μg DNA) but by 48 hr, the PGF_{2 α} concentration had returned to control levels. The increase in the PGE concentration represents one of the earliest effects of TPA observed in the mouse system. The results support the hypothesis that tumor promoters exert part or all of their action through the intervention of PGE₂. (19 refs)

- 79-6799 Mechanism of Tumor Promoter Inhibition of Cellular Binding of Epidermal Growth Factor. (Eng) Lee, L. S. (Div. Environmental Science and Cancer Center, Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., 701 W. 168th St., New York, NY 10032); Weinstein, I. B. *Proc Natl Acad Sci USA* 76(10): 5168-5172; 1979.

The mechanism of 12-O-tetradecanoylphorbol-13-acetate (TPA) inhibition of cellular binding to epidermal growth factor (EGF) was investigated in several cell lines. Exposure of HeLa, mouse 3T3, xeroderma pigmentosum (XP), and rat liver K22 cells to TPA (33 nanograms/ml) resulted in a 50%-90% reduction in the cellular binding of ^{125}I -EGF. The other four cell cultures examined (CHO, B16, HTC, and CEF) had negligible levels of EGF receptors in the absence of TPA, so no significant effect of TPA on EGF binding could be detected. In HeLa cells, TPA also accelerated the loss of previously bound EGF from cells. The released EGF was recovered largely intact in the medium, which indicates that TPA does not induce increased proteolysis or increased cellular internalization and degradation of EGF. TPA inhibition of EGF binding and TPA-induced release of prebound EGF were much greater at 22 C and 37 C than at 4 C. Cells grown in TPA for ≥ 1 day escape or become refractory to TPA inhibition of EGF binding. These results suggest that TPA inhibits EGF binding indirectly by altering the conformation of or inducing the clustering of EGF receptors. (39 refs)

- 79-6800 Effects of 12-O-Tetradecanoylphorbol-13-acetate and Mezerein on Epidermal Ornithine Decarboxylase Activity, Isoproterenol-stimulated Levels of Cyclic Adenosine 3':5'-Monophosphate, and Induction of Mouse Skin Tumors In Vivo. (Eng) Mufson, R. A. (Inst. Cancer Res., Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168th St., New York, NY 10032); Fischer, S. M.; Verma, A. K.; Gleason, G. L.; Slaga, T. J.; Boutwell, R. K. *Cancer Res* 39(12): 4791-4795; 1979.

The tumor promoter 12-O-tetradecanoylphorbol-13-acetate (TPA) and the antileukemic agent mezerein, plant diterpene esters with certain structural similarities, were applied topically to mouse skin [varying doses of 1.7 or 17 nanomoles (nm), 0.34 or 3.4 nm, and/or 8.5 nm tested in some or all experiments]. The compounds were equipotent on a molar basis in inducing hyperplasia, inflammation, and ornithine decarboxylase activity, as well as in reducing cyclic adenosine 3':5'-monophosphate accumulation in response to β -adrenergic stimulation. In contrast, mezerein was much less effective as a tumor promoter; TPA at 8.5 nm/application yielded 78-fold more tumors than did 8.5 nm mezerein/application to similarly initiated (0.1 μm dimethylbenz(a)anthracene) SENCAR mice. The superiority of the phorbol ester was nearly as great in CD-1 mice. These results suggest that although the induction of hyperplasia and ornithine decarboxylase activity may be necessary components of the carcinogenic process, they are not sufficient; TPA must accomplish an essential event not accomplished by mezerein. (32 refs)

- 79-6801 Tumour Promoters Enhance Anchorage-independent Growth of Adenovirus-transformed Cells Without Altering the Integration Pattern of Viral Sequences. (Eng) Fisher, P. B. (Cancer Center/Inst. Cancer Res., Div. Environmental Sciences, Dept. Microbiology, Columbia Univ., Coll. Physicians and Surgeons, New York, NY 10032); Dorsch-Hasler, K.; Weinstein, I. B.; Ginsberg, H. S. *Nature* 281(5732): 591-594; 1979.

The effect of 12-O-tetradecanoylphorbol-13-acetate (TPA) on the acquisition of anchorage-independent growth (growth in soft agar) by adenovirus type 5 (Ad 5)-transformed secondary rat embryo (RE) cells was studied. TPA appreciably enhanced the agar cloning efficiency of the Ad 5-transformed, but not untransformed, RE cells. The optimal effect was achieved with 3 ng/ml TPA, a half-max effect being achieved with 1 ng/ml. The non-tumor promoters

phorbol and 4 α -phorbol-12,13-didecanoate did not enhance growth of transformed RE cells in agar. The TPA enhancement of anchorage-independent growth was not reversible by subcloning. The av doubling times of the anchorage-independent clones were shorter and the saturation densities higher than those of normal RE cells. The changes in cell phenotype induced by TPA were not due to alterations in the extent or state of integration of Ad 5 sequences in the genome of the host cell. (24 refs)

- 79-6802 Quantitative Assessment of Generalized Epithelial Changes in Tracheal Mucosa following Exposure to 7,12-Dimethylbenz(a)anthracene. (Eng) Topping, D. C. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Griesemer, R. A.; Nettesheim, P. *Cancer Res* 39(12): 4823-4828; 1979.

Sequential morphological changes following brief carcinogen exposures of heterotopic tracheal transplants in rats were semi-quantitatively studied. Tracheas were exposed to 7,12-dimethylbenz(a)anthracene for 1, 2, or 4 wk; mean dosages of carcinogen were 138, 152, and 160 μg , respectively. The first two exposure levels resulted in generalized epithelial changes only; these included hyperplasia and early metaplasia, both of which regressed rapidly, and persistent atrophic alterations. No focal epithelial lesions or tumors developed. The 160 μg exposure resulted in the appearance of generalized mucosal changes with long-lasting, severe inhibition of mucus production. In addition, focal metaplastic lesions reappeared at 4 to 8 mo after exposure; and invasive carcinomas developed at 1 yr with an incidence of 9%. Overall carcinoma incidence, including carcinoma in situ, was 15%. These studies emphasize the importance of the duration of carcinogen exposure and demonstrate the emergence of focal lesions when effective carcinogenic exposures are used. The possible significance of epithelial atrophy in the pathogenesis of cancer is discussed. (24 refs)

- 79-6803 Effects of Prostaglandins and Some Anti-inflammatory Drugs on the Binding of 7,12-dimethylbenz(a)anthracene to the DNA of Murine Epidermal Cells in Culture. (Eng) Shoyab, M. (Meloy Lab., Inc., 6715 Electronic Drive, Springfield, VA 22151). *Cancer Lett* 7(1): 155-162; 1979.

The effects of prostaglandins and some anti-inflammatory drugs such as acetylsalicylic acid, flufenamic acid, indomethacin, and flucinolone acetone (FA) on the binding of [^3H]7,12-dimethylbenz(a)anthracene (DMBA) to DNA of murine epidermal cells were investigated. Prostaglandin E_1 and Prostaglandin E_2 significantly inhibited the binding of DMBA to murine epidermal cells (MEC) DNA, while Prostaglandin $\text{F}_{1\alpha}$ and Prostaglandin $\text{F}_{2\alpha}$ did not affect the binding. Salicylic acid and flufenamic acid also did not alter the binding, whereas, indomethacin and FA lowered the binding. (36 refs)

- 79-6804 Biochemical Basis for Cytotoxicity of 7,12-Dimethylbenz(a)anthracene in Rat Liver Epithelial Cells. (Eng) Iype, P. T. (Chemical Carcinogenesis Program, NCI, Frederick Cancer Res. Center, Frederick, MD 21701); Tomaszewski, J. E.; Dipple, A. *Cancer Res* 39(12): 4925-4929; 1979.

The effects of 7,12-dimethylbenz(a)anthracene (DMBA) on a normal liver epithelial cell line, NRL 11, and on a hepatocellular car-

cinoma cell line, HL 5, were compared. The cells were incubated with DMBA (0.001, 0.01, 0.1 or 1.0 $\mu\text{g/ml}$), and the relative plating efficiency was determined. At concentrations ≥ 0.01 $\mu\text{g/ml}$, DMBA dramatically reduced survival of normal cells, whereas, even at 1.0 $\mu\text{g/ml}$, it only marginally inhibited growth of the hepatoma cell line. The cytotoxicity was abrogated by coincubation of NRL 11 cells with 7,8-benzoflavone, which inhibits DMBA metabolism. The binding of DMBA metabolites to DNA was measured in each cell line after a 24 hr incubation with 0.05 $\mu\text{g/ml}$ DMBA. The binding in each line was low (4.1 and 5.6 $\mu\text{mol/mol}$ DNA phosphorus for HL 5 and NRL 11, respectively). Chromatographic analysis of the DMBA-nucleoside adducts revealed no qualitative differences between the two lines. Hepatoma cells, however, were more efficient than normal cells in generating very polar metabolites (not organic-solvent-extractable). These results suggest that the basis for the selective toxicity of DMBA may be that toxic metabolites are more efficiently conjugated or otherwise detoxified in the resistant HL 5 cultures. Several phenols were examined as the possible toxic metabolites of DMBA, but none approached the toxicity exhibited by DMBA itself. (32 refs)

- 79-6805 **Excision of DNA Damage Arising from Chemicals of Different Carcinogenic Potencies.** (Eng) Dipple, A. (NCI Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701); Schultz, E. *Cancer Lett* 7(2/3): 103-108; 1979.

The excision of DNA-adducts generated by 7-bromomethylbenz(a)anthracene or 7-bromomethyl-12-methylbenz(a)anthracene was compared in two cell culture systems: primary C3H mouse embryo cell cultures and mouse L 929 cells in suspension culture. The cells were treated with 0.25, 0.50, 0.75, and 1.0 μM bromocompound; DNA was extracted from the treated cells and subjected to gradient centrifugation in cesium chloride. The dose-response curves for binding of each carcinogen to DNA were similar in both culture systems and, for both compounds, binding to DNA increased linearly with dose. The embryo cells were more efficient in excising DNA-bromocompound adducts than were the L 929 cells. In the embryo cells, excision was estimated at 60% and 67% for 7-bromomethylbenz(a)anthracene at 0.25 and 0.50 μM , whereas in the L 929 cells it was 25%, 24%, and 22% at 0.50, 0.75, and 1.0 μM , respectively. Similar results were found with the 12-methylbromo compound. Although the data for the different cell types yielded different relationships, for each cell line, the data for either compound followed the same relationship. Irrespective of which bromocompound was used, an av of approx 1.5% of the initial damage was removed per hr in the L cell suspensions, and 2.8% was removed per hr in embryo cell cultures. The results indicate that differences in the carcinogenic potency of the two compounds cannot be attributed to differences in the excisability of their DNA-adducts. (20 refs)

- 79-6806 **Shapes of Carcinogenic Benz(a)anthracenes: The Crystal and Molecular Structure of 1-Methylbenz(a)anthracene.** (Eng) Jones, D. W. (Sch. Chemistry, Univ. Bradford, Bradford, West Yorkshire, BD7 1DP, England); Sowden, J. M. *Cancer Biochem Biophys* 4(1): 43-47; 1979.

The crystal structure of 1-methylbenz(a)anthracene, a weak carcinogen, was determined by application of direct methods to single-crystal x-ray diffractometric data and refined by least squares to $R = 0.09$ over 845 independent reflections. Crystals are monoclinic, space group $P2_1$, with $a = 8.491(2)$, $b = 7.138(2)$, $c =$

$10.500(2)$ Å, $\beta = 95.06(01)^\circ$, $Z = 2$. As in other benz(a)anthracenes, the K-region bond C(5)-C(6) is short [1.34(1)Å]. The distinctive bay geometry, with a methyl group opposite to a hydrogen, H(12), *peri* to another hydrogen, H(11), features a long bond C(13)-C(18) = 1.47(1) Å in the bay; and the angular benz-ring is inclined at 16.5° to the mean plane of the anthracene fragment. The methyl carbon atom is 0.79 Å out of the mean molecular plane (or 0.19 Å out of the plane of the benz-ring) and the 1.50 Å long C(1)-methyl bond makes angles of 117° and 125° at C(1). (19 refs)

- 79-6807 **Covalent Binding of Polycyclic Aromatic Hydrocarbons to Adenine Correlates with Tumorigenesis in Mouse Skin.** (Eng) DiGiovanni, J. (Dept. Pharmacology, Sch. Medicine, Univ. Washington, Seattle, WA 98195); Romson, J. R.; Linville, D.; Juchau, M. R.; Slaga, T. J. *Cancer Lett* 7(1): 39-43; 1979.

The possible association between skin-tumor initiation and covalent binding of several polycyclic aromatic hydrocarbons (PAH) was studied in vitro. Epidermal homogenates from female CD-1 mice were used to convert the PAH to metabolites capable of binding covalently with nucleic acids. Poly(G) showed the greatest capacity to bind covalently with the PAH, but there was no correlation between binding to poly(G) and tumorigenicity for mouse skin. Covalent binding to poly(A) did, however, correlate well with values obtained for binding to DNA and mouse skin tumorigenicity. The order of binding to poly(A) was: 7,12-dimethylbenz(a)anthracene > benzo(a)pyrene > dibenz(a,h)anthracene > dibenz(a,c)anthracene. It is suggested that binding to adenine may be critical in terms of PAH carcinogenesis in mouse skin. (23 refs)

- 79-6808 **The Induction of Sister Chromatid Exchanges by Dihydrodiols Derived from 7,12-Dimethylbenz(a)anthracene and 3-Methylcholanthrene.** (Eng) Pal, K. (Chester Beatty Res. Inst., Fulham Road, London SW3 6JB, England); Grover, P. L.; Sims, P. *Cancer Lett* 7(1): 45-49; 1979.

The induction of sister chromatid exchanges (SCE) in cultured Chinese hamster ovary (CHO) cells by the polycyclic hydrocarbons, 7,12-dimethylbenz(a)anthracene (DMBA) and 3-methylcholanthrene (MCA) and some of the related dihydrodiols was investigated. Increased numbers of SCE occurred in the chromosomes of cells exposed to non-K-region dihydrodiols. The most active compounds were the 3,4-dihydrodiol of DMBA and the 7,8- and 9,10-dihydrodiols of MCA; the parent hydrocarbons and their corresponding K-region dihydrodiols were relatively less active. The results are consistent with those of other studies that suggest that the metabolic activation of both hydrocarbons proceeds through the conversion of non-K-region dihydrodiols into vicinal diol-epoxides. (7 refs)

- 79-6809 **Binding of Epidermal Growth Factor to Primary and Permanent Cultures of Mouse Epidermal Cells: Inhibition by Tumor-promoting Phorbol Esters.** (Eng) Murray, A. W. (Sch. Biological Sciences, Flinders Univ., South Australia 5042, Australia); Fusenig, N. E. *Cancer Lett* 7(2/3): 71-77; 1979.

The binding of epidermal growth factor (EGF) to primary and permanent cultures of mouse epidermal cells was studied with and

without the addition of tumor-promoting phorbol esters. EGF bound to all three epidermal cell types tested: primary epidermal cell cultures (PEC), a mouse epidermal cell line transformed in vitro by 7,12-dimethylbenz(a)anthracene (PDV), and a spontaneously transformed cell line (HEL/37). Binding of EGF to all cells tested was strongly inhibited by 12-O-tetradecanoyl-phorbol-13-acetate (TPA) and phorbol-12,13-didecanoate, which are powerful tumor-promoting agents, but not by their nonpromoting derivatives, 4-O-methyl-tetradecanoylphorbol-13-acetate or 4 α -phorbol-12,13-didecanoate, respectively. The TPA concentration required for 50% of the max inhibition was 2.3×10^{-9} M. Binding was inhibited <7% by a 30-fold excess of other peptide hormones, indicating that the interaction of TPA with receptor sites was specific for EGF. Preliminary results of studies of the nature of this interaction suggest that it is noncompetitive. The present results suggest that the biological activity of phorbol esters in epidermal cultures may be significant for their mechanism of action in vivo. (25 refs)

- 79-6810 Mechanism of Ovarian Carcinogenesis: Effect of 7,12-Dimethylbenz(a)anthracene Administration on Intrasplenic Ovarian Grafts in Unilaterally Ovariectomized C3HeB/Fe Mice. (Eng) Armuth, V. (Weizmann Inst. Science, Rehovot, Israel); Berenblum, I. *J Natl Cancer Inst* 63(4): 1047-1050; 1979.

The mechanism of chemically induced ovarian neoplastic transformation was investigated. A single po administration of 7,12-dimethylbenz(a)anthracene (DMBA) 2 wk after intrasplenic grafting of ovarian tissue in unilaterally ovariectomized C3HeB/Fe mice resulted in a high tumor incidence (47%) in the grafted tissue, with only one tumor (3%) in the orthotopic ovary. No tumors occurred in unilaterally ovariectomized controls that received intrasplenic ovarian tissue grafts without subsequent DMBA administration, nor did tumors develop in response to DMBA treatment in mice with both ovaries in situ and no grafted tissue in the spleen. The results indicate that some local change caused by the grafting procedure rendered the tissues more sensitive to the action of DMBA and/or more responsive to gonadotropic stimulation. (20 refs)

- 79-6811 Inhibition of Preovulatory Gonadotropin Secretion and Stimulation of Prolactin Secretion by 7,12-Dimethylbenz(a)anthracene in Sprague-Dawley Rats. (Eng) Kerdelhue, B. (Laboratoire des Hormones Polypeptidiques, Centre Natl. de la Recherche Scientifique, 91190 Gif-sur-Yvette, France); El Abed, A. *Cancer Res* 39(11): 4700-4705; 1979.

Serum luteinizing hormone, follicle-stimulating hormone, prolactin, thyroid-stimulating hormone, growth hormone and hypothalamic luteinizing hormone and thyroliberin contents were measured at given times of the estrous cycle in dimethylbenz(a)anthracene (DMBA)-susceptible Sprague-Dawley rats and in DMBA-resistant Wistar rats for periods up to the appearance of the first mammary tumors in DMBA-susceptible animals. Tumors usually appeared with approx 100% incidence around the 14th to 15th estrous cycle after DMBA treatment in Sprague-Dawley rats. Hormonal determinations were done by using groups of 4-day cycling rats of both strains which were given DMBA (15 mg) or the vehicle (sesame oil) on a single diestrus I at around 55 days of life. Animals were sacrificed by decapitation without previous anesthesia on the morning and afternoon of proestrus and estrus during the 5th and 11th estrous cycles after treatment. In Sprague-Dawley female rats,

DMBA significantly inhibited luteinizing hormone and follicle-stimulating hormone surges and stimulated the prolactin surge on the afternoon of proestrus at any estrous cycle after treatment (the timing of preovulatory surges was the same in both strains for any hormone at other times of the estrous cycle). In contrast, Wistar rats did not show deranged preovulatory or basal prolactin and gonadotropin release after treatment with the carcinogen; in addition, no difference was found for any other hormone at any time tested. These results show that there is a specific and transient hormonal deregulation in a DMBA-susceptible strain of rats. Inasmuch as the hormonal imbalance was essentially the same throughout the induction period, an early and persistent alteration in centers implicated in the hormonal cyclicality of the hypothalamopituitary axis must result from DMBA treatment. (17 refs)

- 79-6812 Transformation of Hamster Fetal Cells by Nitrosated Pesticides in a Transplacental Assay. (Eng) Quarles, J. M. (Dept. Medical Microbiology and Immunology, Coll. Medicine, Texas A & M Univ., College Station, TX 77843); Segal, M. W.; Schenley, C. K.; Lijinsky, W. *Cancer Res* 39(11): 4525-4533; 1979.

The transplacental host-mediated hamster cell culture assay was used to test a series of solvents, control chemicals, and pesticides and their corresponding N-nitroso derivatives for transforming activity. In addition to testing for morphological transformation, growth of cells suspended in 0.3% agar and tumorigenicity in nude mice were also determined. Since no transforming activity was detected during examination of approx 38,000 colonies from cultures obtained from untreated animals nor from the 22,000 colonies of cells from animals treated with only solvents, the possible occurrence of spontaneous or solvent-induced transformation did not pose any significant problem. Cells exhibiting transformed morphology, growth in soft agar, and tumorigenicity in nude mice were obtained from fetal cell cultures of pregnant hamsters treated with several known carcinogens [eg, diethylnitrosamine, nitrosomethylurethane, and 7,12-dimethylbenz(a)anthracene] and all the nitrosated pesticides tested, including the N-nitroso derivatives of carbaryl, carbofuran, Baygon, Landrin, Bux Ten, methomyl, and aldicarb. The parent pesticides were found to be nontransforming in this study, with the exceptions of infrequent morphological transformation without growth in soft agar or tumorigenicity by Landrin and Bux Ten. The transplacental host-mediated assay was shown to be useful in determining transforming activity in a variety of chemicals of known and unknown carcinogenicity especially when used in conjunction with the soft agar assay. (31 refs)

- 79-6813 Studies with Chlorinated Dibenzo-*p*-Dioxins, Polybrominated Biphenyls, and Polychlorinated Biphenyls in a Two-Stage System of Mouse Skin Tumorigenesis: Potent Anticarcinogenic Effects. (Eng) Berry, D. L. (Cancer and Toxicology Program, Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Slaga, T. J.; DiGiovanni, J.; Juchau, M. R. *Ann NY Acad Sci* 320: 405-414; 1979.

The ability of chlorinated dibenzo-*p*-dioxins, polybrominated biphenyls (PBBs), and polychlorinated biphenyls (PCBs) to modify tumor initiation in a mouse skin assay was studied in female CD-1-mice. Topical 12-O-tetradecanoylphorbol-13-acetate (TPA) caused marked inflammation and increased layers of intrafollicular epidermis (IFE). 2,3,7,8-Tetrachlorodibenzo-

p-dioxin (TCDD) caused some increase in the number of cells in the IFE; PCBs and PBBs did not affect the IFE, and 2,7-dichlorodibenzo-*p*-dioxin (DCDD) and 3,4',3',4'-tetrachloroazobenzene (TCAB) did not cause increased thickening of the IFE. The two biphenyls and TCDD did not promote the development of skin tumors following 7,12-dimethylbenz(a)anthracene (DMBA) initiation. Aroclor 1254 and TCDD were very weak tumor initiators, but they decreased DMBA initiation by 45% and 93%, respectively. DCDD slightly inhibited DMBA initiation, and TCAB slightly enhanced it. The inhibition of DMBA initiation by TCDD was related to the ability of TCDD to induce epidermal monooxygenases, which are responsible for converting DMBA to a variety of hydroxylated products. TCDD pretreatment reduced the binding of subsequently applied DMBA to epidermal DNA and, to a lesser extent, RNA; it had no effect on the binding of DMBA to epidermal protein. (36 refs)

PAH either had no significant effect or had a slight enhancing effect on skin tumor initiation by BP. BeP also had essentially no effect on initiation by \pm benzo(a)pyrene-7 β ,8 α -diol-9 α , 10 α -epoxide. BeP at 252 μ g showed weak tumor initiating capacity, and at 100 μ g, no tumor initiating capacity was present. When administered 2x/wk at 100 μ g, BeP had induced 2.1 papillomas per mouse at 30 wk, and 25% of the mice had carcinomas by 40 wk. A comparable response was obtained with 5 μ g BP 2x/wk. When administered at 100 μ g 2x/wk following DMBA initiation, BeP induced 4.5 papillomas per mouse at 30 wk, and there was an incidence of 45% at 40 wk. Thus, BeP is a weak complete carcinogen, a moderate tumor promoter, possibly a weak co-initiator when given with BP, and a potent anti-tumor-initiator when administered with DMBA. The anti-tumor initiating and co-initiating effects of BeP appear to be related to its ability to modify the conversion of the tumor initiator to an electrophilic intermediate(s) capable of covalently binding to DNA. BeP also induced epidermal cell proliferation, which may be related to its promoting ability. (31 refs)

79-6814 Development and Fate of Focal Epithelial Lesions in Tracheal Mucosa Following Exposure to 7,12-Dimethylbenz(a)anthracene. (Eng) Topping, D. C. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Griesemer, R. A.; Nettesheim, P. *Cancer Res* 39(12): 4829-4837; 1979.

Rat tracheas transplanted sc to the backs of syngeneic host animals were implanted with intraluminal pellets containing 165 μ g 7,12-dimethylbenz(a)anthracene (DMBA) for 4 wk. Groups of tracheas were examined histologically 2-12 mo after exposure. Between 2 and 4 mo, 62%-72% of the tracheas sampled contained focal lesions; this declined to 44% at 12 mo. The number of lesions per trachea (2.8-3.5 lesions/trachea) remained relatively constant between 2 and 12 mo. Metaplasias with no or minimal atypia were the most common lesions. The drop in the incidence of lesions between 4 and 12 mo was due to a decrease in the frequency of this type of lesion, indicating that it is reversible. There was a fourfold increase in the incidence of advanced lesions, from 8% at 2 mo to 36% at 12 mo. The first invasive carcinomas were observed at 4 mo; the incidence was 5%, and this incidence did not change significantly during the rest of the study. Some carcinogen-exposed transplants were examined for tumor induction over a 28-mo period. Invasive squamous cell carcinomas occurred 10-22 mo after pellet removal in 8/86 tracheas, and advanced lesions occurred in 9/86 (4 severe atypias, 2 carcinomas in situ, and 3 microinvasive carcinomas). No advanced lesions were detected in 32 tracheas obtained after 20 mo, which indicates that the trend in reduction of lesions with time seen in the serial sampling study is real. These studies indicate that a considerable number of DMBA-induced tracheal lesions remain stationary for a long period and that many others, including some advanced lesions, regress. (27 refs)

79-6815 The Effects of Weak or Non-carcinogenic Polycyclic Hydrocarbons on 7,12-Dimethylbenz(a)anthracene and Benzo(a)pyrene Skin Tumor Initiation. (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830); Jecker, L.; Bracken, W. M.; Weeks, C. E. *Cancer Lett* 7(1): 51-59; 1979.

The effects of weakly and noncarcinogenic polycyclic aromatic hydrocarbons (PAH) on skin tumor initiation by 7,12-dimethylbenz(a)anthracene (DMBA) and benzo(a)pyrene (BP) were studied in female CD-1 mice. Benzo(e)pyrene (BeP) inhibited DMBA skin tumor initiation by 84%, whereas pyrene and fluoranthene were only 50% and 34% inhibitory, respectively. These

79-6816 Neovascularization During Hamster Cheek Pouch Carcinogenesis Induced by 7,12-Dimethylbenz(a)anthracene. (Eng) Tatematsu, M. (First Dept. Pathology, Nagoya City Univ. Medical Sch., 1 Kawasumi, Mizuho-cho, Mizuho-ku, Nagoya 467, Japan); Nakatsuka, T.; Lurie, A. G.; Rippey, R. M.; Suzuki, M.; Ito, N. *Gann* 70(5): 719-720; 1979.

The cheek pouches of 100 male golden hamsters were treated with 0.05 ml of a 0.5% 7,12-dimethylbenz(a)anthracene (DMBA) soln in mineral oil 3x/wk for 14 wk, with no application during wk 3, 7, and 11. Cheek pouches were examined histopathologically and by scanning electron microscopy after sacrifice 2-30 wk after the start of DMBA treatment. Normal cheek pouches had loose plexi of capillaries, which were relatively uniform and present in low density. Small foci of high-density plexi of small diameter capillaries (type I) were occasionally seen in DMBA-treated cheek pouches. They were most frequent at wk 4 and had disappeared by wk 14. Type III foci, highly tortuous capillary loops without terminal branches, were first seen at 6 wk and increased gradually in number and extent. After 14 wk, the capillaries became irregular and had a diameter considerably larger than normal. Histologically, mild hyperplasia was seen after wk 6, and small papillomas were found after wk 10. Squamous cell carcinomas occurred after 14 wk. Type I foci may represent repair of direct damage to blood vessels. Type III foci showed a close relationship with epithelial proliferative lesions, hyperplasia, papillomas, or carcinomas, and may represent endothelial responses to secretion of an angiogenic factor from malignant or premalignant tissues. 79-6817 Sialic Acid Metabolism in Rats Undergoing Chemically-induced Mammary Gland Carcinogenesis in Specific Dietary States. (Eng) Fox, O. F. (Biomembrane Res. Lab., Oklahoma Medical Res. Foundation, Oklahoma City, OK 73104); Kishore, G. S.; Carubelli, R. *Cancer Lett* 7(5): 251-257; 1979.

The enzymes responsible for the activation, transfer, and hydrolysis of sialic acids were investigated in female Sprague-Dawley rats with mammary adenocarcinomas induced by administration of a single po dose (10 mg) of 7,12-dimethylbenz(a)anthracene. The carcinogenic process was modulated by the levels and degree of unsaturation of the dietary lipids. Tumor incidence was highest in rats fed a diet containing 20% corn oil, intermediate

in those fed a diet containing 18% coconut oil plus 2% linoleic acid, and lowest in those receiving a diet with 2% linoleic acid. Sialyltransferase and CMP-*N*-acetylneuraminic acid synthetase activities were higher in tumors than in control mammary glands. Neuraminidase activity, on the other hand, was higher in control tissue than in tumors. In addition to these tumor-related effects, comparison of the enzyme levels in mammary tissues from control animals in the three dietary groups revealed the presence of diet-related effects on sialic acid metabolism. In the livers of tumor-bearing rats, only minor changes in enzyme activities were detected. The authors speculate that the enzymatic changes observed in the control mammary tissue of rats fed a low-fat diet may reflect a biochemical environment unfavorable for the malignant transformation of mammary cells. - 79-6818 Inhibition of Mammary Tumorigenesis in Carcinogen-treated Lewis Rats by Suppression of Prolactin Secretion. (Eng) Welsch, C. W. (Dept. Anatomy, Michigan State Univ., East Lansing, MI 48824); Brown, C. K.; Goodrich-Smith, M.; Van, J.; Denenberg, B.; Anderson, T. M.; Brooks, C. L. *J Natl Cancer Inst* 63(5): 1211-1214; 1979.

A total of 168 female Lewis rats were treated intragastrically with 10 mg of 7,12-dimethylbenz[a]anthracene at 56 and 63 days of age. Pituitary prolactin secretion was suppressed in half of these rats by daily sc 2-bromoergocryptine mesylate administration (CB-154: 0.4 mg/100 g body wt) from 29 to 90 days of age (series 1) and from 90 to 140 days of age (series 2). Treatment with CB-154 was initiated prior to the onset of palpable mammary carcinomas. Controls received saline injections. Inguinal mammary glands were excised from 10 control and 10 CB-154-treated rats at the cessation of saline and CB-154 treatments and examined for hyperplastic nodules (HN). The remaining rats were examined weekly for mammary carcinoma (MC) and killed at 200 days of age. The mean number of HN per rat, mean number of MC per rat, and percent of rats with MC were, respectively: series 1-controls, 0.6, 1.5, and 68; CB-154 treatment, 0.5, 1.1, and 62; series 2-controls, 10.4, 2.0, and 94; CB-154 treatment, 5.1, 1.1, and 56. The number of HN and MC was only slightly reduced in rats when prolactin was suppressed during carcinogen treatment (series 1) but markedly reduced when prolactin was suppressed after carcinogen treatment (series 2). These results provide evidence that prolactin is involved in the early development of mammary dysplasias in carcinogen-treated female Lewis rats. (19 refs)

- 79-6819 Induction, Inhibition, and Some Enzymological Properties of Aryl Hydrocarbon Hydroxylase in Fresh Mitogen-activated Human Lymphocytes. (Eng) Gurtoo, H. L. (Grace Cancer Drug Center, Roswell Park Memorial Inst., 666 Elm Street, Buffalo, NY 14263); Parker, N. B.; Paigen, B.; Havens, M. B.; Minowada, J.; Freedman, H. J. *Cancer Res* 39(11): 4620-4629; 1979.

Basal and/or polycyclic aromatic hydrocarbon (PAH)-induced aryl hydrocarbon hydroxylase (AHH) in mitogen-activated cultured lymphocytes obtained from healthy donors was studied for the specificity of induction and inhibition and of other enzymological properties. Of the 24 chemicals tested, 2,3,7,8-tetrachlorodibenzo-*p*-dioxin (TCDD), dibenz(a,h)anthracene (DBA), benz(a)anthracene (BA), 3-methylcholanthrene (3-MC), β -naphthoflavone, cholecalciferol, and DL-isoproterenol were

good inducers (inducibility ratio, >2.0). Other chemicals which produced effects ranging from inhibition to mild induction included 4-bromoflavone, α -naphthoflavone, chrysene, *p,p'*-1,1-trichloro-2,2-bis(*p*-chlorophenyl)-ethane, 7,12-dimethylbenzanthracene, pyrene, DL-norepinephrine, benzo(a)pyrene, lindane, *v*-octylamine, testosterone, 2,5-diphenyloxazole, 17 β -estradiol, metyrapone, and phenobarbital. TCDD was the most potent inducer, followed by DBA \geq BA $>$ 3-MC. The data suggest that the latter four inducers could be used interchangeably as they appear to activate the common, genetically determined factors involved in the induction of AHH. The order of potency among the inhibitors was α -naphthoflavone $>$ β -naphthoflavone, followed by 2-diethylaminoethyl-2,2-diphenylvalerate, metyrapone, 1,1,1-trichloropropene oxide, and cyclohexene oxide. Depending upon the concentration used, the latter four inhibitors produced moderate inhibition to moderate stimulation; however, the inhibition pattern for the basal and the PAH-induced AHH was indistinguishable. The half-life of the enzyme during cell culture and the K_m values of the AHH in uninduced and PAH-induced cells were also similar. Thus, basal and induced AHH appear to be qualitatively similar, differing only quantitatively in comparable uninduced and PAH-induced cells. (52 refs)

- 79-6820 Bioassay of C. I. Vat Yellow 4 for Possible Carcinogenicity. (Eng) National Cancer Institute (NCI, Bethesda, MD 20014). *Natl Cancer Inst Carcinog Tech Rep Ser* (134): 106 pp.; 1979.

Results of the bioassay of C. I. vat yellow 4 (dibenzo(b,def)chrysene-7,14-dione) for the carcinogenesis testing program are reported. Groups of 50 animals of each sex were given yellow 4 in the diet at one of two dose levels. Fischer 344 rats were fed at 3,500 or 7,000 ppm for 104 wk. Male mice (B6C3F1) were given 25,000 or 50,000 ppm, and female mice (same strain) were given 12,500 or 25,000 ppm. Mice were fed for 106 wk. Survival of rats and mice was not decreased by yellow 4. In all rat groups and the female mice groups, no tumors occurred at incidences significantly higher than in the matched control groups (20 rats, 20 mice of each sex). Lymphoma incidence (44%) was higher ($p = 0.019$) in male mice given the higher dose than in the low-dose and control groups (15% incidence). Hepatomas were more frequent (22/47 at the low dose, 21/50 at the high dose) in treated male mice than in the controls (3/20). Although the human risk from yellow 4 is very low, the carcinogenic potential suggested by the increased incidences of lymphomas and hepatomas in male mice indicates that further tests may be required. (18 refs)

- 79-6821 Effect of Protein Synthesis Inhibitors on the Induction of Rat Liver Microsomal Cytochrome P-448 by 3-Methylcholanthrene. (Eng) Poole, T. W. (Dept. Biochemistry, Univ. Surrey, Guildford, Surrey GU2 5XH, England); Parke, D. V. *Biochem Soc Trans* 7(5): 1109-1111; 1979.

The effects of protein-synthesis inhibitors on the induction of rat liver microsomal cytochrome P-448 by 3-methylcholanthrene (MCA: 25 mg/kg, ip) were studied. Thirty min before MCA administration, male Wistar rats received cycloheximide (CH: 2 mg/kg), actinomycin D (2 mg/kg), or α -amanitin (1 mg/kg) ip. Cytochrome P-448 induction was completely prevented by CH, which also prevented an MCA-induced decrease in ethylmorphine *N*-demethylase activity. CH only partly reversed the enhancement of ethoxycoumarin *O*-de-ethylase and biphenyl 2-hydroxylase in-

duced by MCA. Increases in enzyme activities associated with MCA treatment were not completely prevented by CH. (11 refs)

- 79-6822 Susceptibility and Resistance to Chemical Carcinogens in Inbred Syrian Hamsters. (Eng) Homburger, F. (Bio-Res. Inst., 9 Commercial Ave., Cambridge, MA 02141); Adams, R. A.; Soto, E.; Van Dongen, C. G. *Prog Exp Tumor Res* 24: 215-221; 1979.

The comparative susceptibilities of several inbred strains of hamsters to a variety of carcinogens were studied. The data indicate varying degrees of resistance and susceptibility to both spontaneous and induced malignancies, and these appear to be governed by genetic factors. To study carcinogens for which the mammary gland is a target, the female BIO 15.16 hamster would be the preferred model, whereas for intestinal cancer the BIO 15.16 or BIO 87.20 male would be preferred. The BIO 15.16 hamster is a good model for cigarette smoke-induced cancer of the larynx, and bladder cancer would best be studied using one of the inbred lines responding to β -naphthylamine feeding with urothelial carcinomas (eg, the BIO 87.20 male). Hybrids of two susceptible BIO lines (BIO 15.16 \times BIO 87.20) appear to be as susceptible as the parental strains to sc methylcholanthrene; these hybrids might prove to be sturdy, rapidly breeding test animals for carcinogenesis studies. (13 refs)

- 79-6823 Reduction in the Formation of Carcinogen-induced Transformed Foci by Penicillin G Sodium in the C3H/10T_{1/2} CL8 Cell Line. (Eng) Bertram, J. S. (Dept. Experimental Therapeutics, Roswell Park Memorial Inst., Buffalo, NY 14263). *Cancer Lett* 7(5): 289-298; 1979.

As part of a continuing effort to improve an in vitro assay system for malignant transformation that employs the C3H/10T_{1/2} CL8 cell line, experiments were carried out to determine whether Gentamicin could be substituted for the combination of penicillin (100 IU/ml) and streptomycin (50 μ g/ml) that has hitherto been used to reduce the occurrence of bacterial contamination. In preliminary studies, the penicillin component of the mixture had been discovered to cause a reduction in the number of transformed foci developing after exposure of cells to 3-methylcholanthrene, 7,12-dimethylbenzanthracene and x-rays. This reduction was found to be dose dependent; 500 IU/ml virtually eliminated transformation, while 100 IU/ml caused an approx 50% decrease in the number of foci. This effect did not appear to be due to overt toxicity and was largely reversible on removal of the antibiotic. Gentamicin (25 μ g/ml) caused no reduction in the formation of transformed foci when compared with cultures maintained in antibiotic-free medium. Gentamicin also offers the advantages of chemical stability, a wider spectrum of antibacterial activity in comparison with penicillin/streptomycin and is active against many mycoplasma. It is suggested that future studies with this cell line should ideally be performed without antibiotics or should employ Gentamicin for antibacterial protection. (17 refs)

- 79-6824 Carcinoma Induction by 3-Methylcholanthrene in Hamster Tracheal Tissue Implanted in Syngeneic Animals. (Eng) Craighead, J. E. (Dept. Pathology, Univ. Vermont Coll. Medicine, Burlington, VT 05401); Mossman, B. T. *Prog Exp Tumor Res* 24: 48-60; 1979.

The induction of neoplasms in BIO 15.16 strain Syrian golden hamsters by the implantation of hamster tracheal organ cultures exposed to 3-methylcholanthrene (MC) adsorbed onto particles of asbestos and Fe₂O₃ was studied. Cysts often developed after implantation of such organ cultures, the structures appearing to have formed from outgrowths of epithelial cells that proliferated from the margins of the explants. The grafts retained their original structure and mucociliary epithelial lining. Neoplasms developed in implanted tracheal organ cultures 3-17 mo after exposure to MC (0.6-10 μ g/graft). All but 13 of the 67 tumors studied were carcinomas, the exceptions exhibiting features of well-differentiated fibrosarcomas. Cytological features of neoplastic transformation were frequently observed adjacent to the presumed sites of epithelial origin of the neoplasms, and transitions from carcinoma in situ to frankly invasive tumor were commonly demonstrated. In implants not developing tumors, both focal and extensive areas of squamous metaplasia were observed, as were other cytological atypias. Most of the carcinomas were made up of poorly differentiated polygonal cells, although occasional epidermoid, adeno-, and small cell carcinomas were found. (19 refs)

- 79-6825 Use of Hamster Tracheal Organ Cultures for Assessing the Cocarcinogenic Effects of Inorganic Particulates on the Respiratory Epithelium. (Eng) Mossman, B. T. (Dept. Pathology, Univ. Vermont Coll. Medicine, Burlington, VT 05401); Craighead, J. E. *Prog Exp Tumor Res* 24: 37-47; 1979.

Intratracheal instillation of polycyclic hydrocarbons bound to 'carrier' particulates induces respiratory tract neoplasms in laboratory animals. To elucidate the respiratory epithelial changes caused by carcinogens and selected inorganic particles, tracheal organ cultures were prepared from female Syrian golden hamsters (BIO 15.16 strain). Explants were exposed to 3-methylcholanthrene (3-MC) coated onto either ferric oxide or crocidolite asbestos. Control tissues were treated with particulates without 3-MC. At intervals of 24 and 72 hr and 1, 2, 3, and 4 wk, the cultures either were examined morphologically or implanted sc into syngeneic hamsters. Greater amounts of 3-MC were required to induce tumors with Fe₂O₃ than with asbestos. Nine fibrosarcomas and 13 carcinomas were induced in all. Dose-response determinations indicated a degree of precision in these studies unattainable in whole animal models of respiratory carcinogenesis. (18 refs)

- 79-6826 Methylcholanthrene-induced Metastatic Mammary Carcinoma in Several Inbred Hamster Strains. (Eng) Adams, R. A. (Bio-Res. Inst., 9 Commercial Ave., Cambridge, MA 02141); Homburger, F.; Russfield, A. B.; Soto, E. *Prog Exp Tumor Res* 24: 408-413; 1979.

The administration of multiple small doses (total dose 200 mg over a 17-wk period) methylcholanthrene by stomach tube resulted in the induction of metastasizing mammary gland carcinoma in the females of 10 BIO inbred Syrian hamster strains. The incidence of primary induced mammary carcinoma, predominantly papillary cystadenocarcinoma, varied from 39% to 95%; 5 strains had mammary carcinoma incidences above 80%. Grossly observed and histologically verified metastases to one or more lymph nodes were noted in 10-79% of the 142 female hamsters with mammary gland carcinoma (av 42%), multiple lymph node involvement being by far the most frequent finding. Metastasis to the lung, with or without lymph node metastases, was observed in about 13% of the hamsters. Hamsters with mammary gland carcinoma survived 25-

33 wk following the initiation of carcinogen exposure, as compared to 89-100 wk for controls given corn oil only. These high incidences of metastatic mammary carcinoma induced in a relatively short time suggest that some of the inbred BIO hamster strains provide excellent models of metastatic breast cancer. (8 refs)

- 79-6827 Comparison of the Skin Tumor Initiating Activity of 3-methylcholanthrene and 3,11-Dimethylcholanthrene in Mice. (Eng) Slaga, T. J. (Biology Div., Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830); Gleason, G. L.; Hardin, L. *Cancer Lett* 7(2/3): 97-102; 1979.

The skin tumor initiating activities of 3-methylcholanthrene (3-MC) and 3,11-dimethylcholanthrene (3,11-DMC) were compared in female Sencar mice. Groups of 30 7- to 9-wk-old animals received a single topical application of 100 nmol of 3-MC or 3,11-DMC followed 1 wk later by applications of 12-O-tetradecanoylphorbol-13-acetate (TPA: 2 µg 2x/wk). After 16 wk of TPA promotion, 3-MC had induced tumors in 92% of the mice, with an av of 4.5 papillomas/mouse; 3,11-DMC induced tumors in 10% of the mice, with an av of 0.2 papillomas/mouse. The only difference between 3-MC and 3,11-DMC is the substitution of a methyl group in position 11, which is part of the K-region or the peri position. These results suggest that an unhindered peri position adjacent to an angular benzene ring is necessary for carcinogenic activity. (33 refs)

- 79-6828 Metabolism and DNA Binding of 3-Methylcholanthrene. (Eng) Eastman, A. (Dept. Biochemistry, Vermont Regional Cancer Center, Burlington, VT 05405); Bresnick, E. *Cancer Res* 39(11): 4316-4321; 1979.

Rat liver microsomes metabolize 3-methylcholanthrene (3MC) to oxygenated forms which alkylate DNA. Analysis of the DNA-bound products by high-pressure liquid chromatography revealed at least 13 deoxyribonucleoside adducts. The two major adducts contained guanine and had fluorescence spectra consistent with saturation at carbon atoms 7, 8, 9, and 10. Microsome-catalyzed binding of 3MC to double-stranded and single-stranded DNA yielded quantitatively similar patterns, suggesting that specific adducts do not arise from orientation of the hydrocarbon into the DNA helix prior to metabolic activation. The adducts produced in vitro varied with time of incubation; the more polar adducts appeared after longer time periods. Seven of the adducts were also detected in DNA from the lung and liver of C57BL/6J mice that had been given iv injections of 500 µCi [³H]-3MC; the relative amounts of each adduct most closely resembled the pattern which was observed after long incubation of microsomes with DNA in vitro. Microsome-mediated metabolism of [³H]-3MC was also studied. 2-Hydroxy-3-methylcholanthrene, rather than 1-hydroxy-3-methylcholanthrene, was the major metabolite, the latter being barely undetectable. Other metabolites included *trans*-9,10- and *trans*-11,12-dihydrodiols and a variety of unidentified derivatives which may bear modifications on either the saturated five-membered ring or on the 3-methyl group. These derivatives were reincubated with microsomes and DNA. After such incubations, seven 3MC metabolites bound to DNA with higher efficiency than did the parent hydrocarbon; *trans*-9,10-dihydrodiol had the highest efficiency in this regard. The other six metabolites which subsequently showed high binding efficiency appeared to be derivatives on carbon 1, carbon 2, or the 3-methyl. Although the major binding to DNA may be through a vicinal diol-epoxide, the complexity surrounding the aliphatic five-membered

ring probably also contributes to the large number of adducts detected. (32 refs)

- 79-6829 Benzo(a)pyrene Antibody Inhibition of Benzo(a)pyrene-induced Mutagenesis. (Eng) Tompa, A. (Eppley Inst. Res. Cancer, Univ. Nebraska Medical Center, 42nd and Dewey Ave., Omaha, NE 68105); Curtis, G.; Ryan, W.; Kuszynski, C.; Langenbach, R. *Cancer Lett* 7(2/3): 163-169; 1979.

The in vitro effect of a benzo(a)pyrene (BP) antibody on the mutagenic and cytotoxic activity of BP was investigated in a cell-mediated mutagenesis assay. Chinese hamster V79 cells, which cannot metabolically activate BP, were incubated with rat embryo fibroblasts or rat lung epithelial cells with and without BP antibody γ-globulin. Mutagenicity in the V79 cells was measured by induction of resistance to thioguanine and/or ouabain. In the fibroblast-mediated system, BP induced 36 mutants/10⁶ survivors; the presence of the BP antibody reduced the mutation frequency to 13 mutants/10⁶ survivors. In the lung cell-mediated system, BP induced 19 ouabain-resistant mutants/10⁶ and 20 thioguanine-resistant mutants/10⁶ survivors. In the presence of BP antibody, the mutation frequency was six ouabain-resistant mutants/10⁶ and four thioguanine-resistant mutants/10⁶ survivors. BP antibody reduced BP cytotoxicity in both cell-mediated systems. The mechanism of this antibody protection is not known. It is possible that the antibody alters the types of BP metabolites formed or binds to activated intermediates, thereby limiting their interaction with macromolecules in the V79 cells. The level of antibody in vivo may be sufficient to bind an environmental carcinogen encountered in µg/day quantities but not in mg/day quantities. (21 refs)

- 79-6830 Induction of Aryl Hydrocarbon Hydroxylase in Primary Cultures of Type II Alveolar Lung Cells and Binding of Metabolically Activated Benzo(a)pyrene to Nuclear Macromolecules. (Eng) Teel, R. W. (Dept. Physiology and Pharmacology, Sch. Medicine, Loma Linda Univ., Loma Linda, CA 92350). *Cancer Lett* 7(6): 349-355; 1979.

Aryl hydrocarbon hydroxylase (AHH) induction and binding of benzo(a)pyrene (BP), 3-methylcholanthrene (3-MC), and 9,10-dimethyl 1,2-benzanthracene (DMBA) to nuclear macromolecules was studied in alveolar-like structures composed of fetal rat cells resembling type II alveolar pneumonocytes. Cultures were exposed to one of the test compounds (2 µg/ml) for 24 hr and assayed for AHH activity at various times up to 30 days after exposure. With BP, AHH activity reached a peak in 6-day cultures and remained stable over a period of 12 days. There was an abrupt decline in AHH activity after 18 days. In 7-day-old cultures, AHH activity induced by DMBA was 20% of that induced by BP, and 3-MC-induced AHH activity was only 6% that of BP. Six-day cultures were incubated with [³H]BP for 24 hr at 2 µCi/ml culture medium, and the binding of BP metabolites to DNA, histone, and nonhistone proteins was determined. Although binding occurred with all three nuclear fractions, it was preferential for nonhistone proteins. Although there is more evidence to support the interaction of metabolites with DNA in the carcinogenic process, interaction with proteins concerned with the regulation of gene expression may be of significance. (22 refs)

- 79-6831 Effects of Asbestos, Iron Oxide, Silica, and Carbon Black on the Microsomal Availability of

Benzo[a]pyrene. (Eng) Lakowicz, J. R. (Dept. Biochemistry, Univ. Minnesota, Navarre, MN 55392); Bevan, D. R. *Biochemistry* 18(23): 5170-5176; 1979.

Adsorption of the carcinogen benzo(a)pyrene (BP) to iron oxide, silica, and asbestos (anthophyllite and Canadian chrysotile) was found by fluorescence spectroscopy to increase BP uptake in rat liver microsomes, compared with uptake from aqueous dispersions of BP microcrystals. Asbestos particles were more effective than silica and iron oxide in enhancing microsomal uptake of BP. Except for chrysotile, the particles did not disrupt microsomal integrity. Binding of the microsomes to the particles did not affect BP uptake rates. Uptake rates were also independent of microsome and particle concentrations. Adsorption of BP to the particle surface was necessary for enhanced microsomal uptake. Particles, especially fibrous mineral particulates, may thus be cocarcinogenic as a result of their ability to adsorb polynuclear aromatic hydrocarbons and to transport these carcinogens into cells. (37 refs)

- 79-6832 Inhibitory Effect of the Antioxidant Butylated Hydroxyanisole on the Activation of the Carcinogen Benzo(a)pyrene. (Eng) Piekarski, L. (Medical Acad., 02-097 Warsaw, Poland); Sawicki, J.; Kugaczewska, M.; Potocki, L. J.; Sankowski, A.; Uszynski, H.; Malunowicz, E.; Wojciechowska, M.; Kolodziejska, A.; Fox, C. H. *Neoplasma* 26(2): 139-144; 1979.

To investigate the effects of antioxidants on carcinogen and carcinogen metabolite binding to DNA, cultured mouse embryo cells, human skin, and human lymphocytes were incubated with rat liver microsomes and tritium-labeled benzo(a)pyrene (BP: 8.3-25 Ci/mmol) with and without butylated hydroxyanisole (BHA: 0.2 μ mol/ml medium) for 24-48 hr. The amount of BP metabolites bound to DNA in mouse embryo cells and human skin decreased in the presence of BHA, but there was no effect in human lymphocytes. The effect of BHA on BP-DNA binding was also determined for those metabolites of BP extracted in the organic phase. Diols decreased in skin and lymphocyte cultures in the presence of BHA after 48 hr. In mouse embryo cells, there was an increase in phenol when BHA was present in the medium. It is suggested that the decrease in procarcinogen activation, a direct action on biocarcinogens, and increases in procarcinogen and biocarcinogen detoxification could all occur as an effect of BHA. (21 refs)

- 79-6833 Qualitative Changes in the Biologic Characteristics of Cultured Fetal Rat Keratinizing Epidermal Cells During the Process of Malignant Transformation After Benzo(a)pyrene Treatment. (Eng) Indo, K. (Dept. Pathology, Hyogo Coll. Medicine, 1-1, Mukogawa-cho, Nishinomiya, Hyogo, Japan); Miyaji, H. *J Natl Cancer Inst* 63(4): 1017-1027; 1979.

Qualitative changes in the biologic characteristics of fetal SD rat keratinizing epidermal cells undergoing malignant transformation induced by benzo(a)pyrene (BP: 1 μ g/ml) were studied. BP-treated cells at 30 C remained in the premalignant stages and showed shifts in chromosome structure toward the hypodiploid range and parakeratotic changes in their keratinization processes. However, the cells failed to form colonies, even on a plastic substrate. BP-treated cultures that adapted to 35 C or 37.5 C also remained in the premalignant stages, but they acquired the ability to form colonies on plastic substrates during subcultivation. Some transformed colonies appeared among such colonies. Cells showing atypical

keratinization (columnar, spherical, or single-cell types) formed squamous cell carcinomas following injection into syngeneic hosts. The transformed cells showed shifts in chromosome structure toward the hypotetraploid range and formed colonies on 0.57% agar medium, but they failed to form colonies in 0.33% soft agar medium. The cultured cells were classified into five stages of transformation, stage III appearing to be the key step in the process of malignant transformation. (23 refs)

- 79-6834 Induction of Ouabain-resistant Mutation and Sister Chromatid Exchanges in Chinese Hamster Cells with Chemical Carcinogens Mediated by Human Pulmonary Macrophages. (Eng) Hsu, I. C. (Human Tissue Studies Sec., Lab. Experimental Pathology, NCI, Division Cancer Cause and Prevention, Bethesda, MD 20205); Harris, C. C.; Yamaguchi, M.; Trump, B. F.; Schafer, P. W. *J Clin Invest* 64(5): 1245-1252; 1979.

The ability of pulmonary macrophages (PAM) from 20 individuals to mediate mutations and increases in sister chromatid exchanges (SCE) in Chinese hamster V79 cells was studied. PAM metabolically activated benzo(a)pyrene (BP) and its proximate carcinogenic metabolite, (\pm) trans-7,8-dihydroxy-7,8-dihydroBP (7,8-diol), to ultimate mutagens for V79 cells. Increases in the frequency of ouabain-resistant (OR) mutations and SCEs were found only when the V79 cells were cocultivated with both PAM and the chemical procarcinogens. When metabolically activated by PAM, the mean OR mutation frequency caused by BP was $9/10^6$ survival V79 cells/ 10^6 PAM, and a 10-fold interindividual variation (2-21) was observed. The mean OR mutation frequency caused by 7,8-diol was 64, a range of 14-120 being observed. In the absence of PAM, the OR mutation frequency in V79 cells was <1 mutant/ 10^6 survivors. 7,8-Benzoflavone (BF), an inhibitor of mixed function oxidases, reduced the frequency of BP and 7,8-diol induced OR mutations and SCEs in V79 cells. BF did not influence the frequency of OR mutations caused by (\pm)7 β ,8 α -dihydroxy-9 α ,10 α -epoxy-7,8,9,10-tetrahydroBP, an ultimate mutagen of BP and 7,8-diol. The data support the hypothesis that PAM may play a role in the activation of environmental chemical procarcinogens. (27 refs)

- 79-6835 Chromosome Aberrations Induced by Benzo(a)pyrene in a Feeder Cell-mediated Assay. (Eng) Nishi, Y. (Section Cell Biology and Cytogenetics, Biological Res. Center, Japan Tobacco and Salt Public Corp., Hatano, Kanagawa 257, Japan); Mori, M.; Inui, N. *Toxicol Lett* 4(4): 275-280; 1979.

Chromosome aberrations induced by benzo(a)pyrene (Bp) in V79 cells were studied in the presence or absence of feeder cells. In the presence of feeder cells, chromosome aberrations at Bp concentrations of 1.0-20.0 μ g/ml depended on feeder cell density. The highest incidences of chromosome aberrations (aberrant cells) and of aberrant chromosomes per 100 metaphase cells were 24.0% and 38.0%, respectively, and were obtained at 20.0 μ g/ml Bp in the presence of 2.0×10^6 feeder cells/60-mm plastic dish. Chromosome aberrations were not induced in the absence of feeder cells. The incidences of aberrant cells and chromosomes on treatment with Bp in the absence of a feeder layer were 3.0-5.0% and 3.0-6.0%, respectively, while the spontaneous rate was 5.0% for both. - 79-6836 Analysis of Faeces for Benzo(a)pyrene After Consumption of Charcoal-broiled Beef by Rats and

Humans. (Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY 10595); Grabowski, W.; Groth, K. *Food Cosmet Toxicol* 17(3): 223-227; 1979.

Fecal excretion of benzo(a)pyrene (BP) and its metabolites was studied in male F-344 rats after the administration of various doses of ^{14}C -labeled BP by gavage, and fecal excretion of unchanged BP was investigated in rats and humans after they consumed charcoal-broiled meat containing BP. In groups of 10 rats that received ^{14}C -labeled BP (0.04, 0.4, 4.0 $\mu\text{mol}/\text{rat}$), 74%-79% of the dose was excreted in the feces within the first 48 hr. The proportion of BP excreted unchanged was 13.0%, 7.8%, and 5.6% for the 0.04, 0.4, and 4.0- μmol doses, respectively. The metabolites identified were 3-hydroxybenzo(a)pyrene (3% of dose); 9-hydroxybenzo(a)pyrene (<1%); benzo(a)pyrene-3,6-dione (3%); benzo(a)pyrene-1,6-dione (6%); 4,5-dihydro-4,5-dihydroxybenzo(a)pyrene (<1%); and 7,8-dihydro-7,8-dihydroxybenzo(a)pyrene (<1%). The concentration of BP in a typical sample of broiled beef was $52.7 \pm 6.8 \mu\text{g}/\text{kg}$. Unchanged BP in the feces of rats fed 0.1 kg of beef containing 5.3 μg of BP was 0.6 μg (11% of the dose). No BP was detected in the feces of the eight men who each consumed 357 g of charcoal-broiled beef (8.6 μg BP/person). The detection limit was 0.05 μg BP/total fecal sample; recovery of internal standard ^{14}C -labeled BP was 65% of the dose. (19 refs)

79-6837 Comparative Metabolism of Benzo(a)pyrene in Rodent Liver and Embryonic Cells in Tissue Culture. (Eng) Selkirk, J. K. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Wiebel, F. J. *Prog Exp Tumor Res* 24: 61-72; 1979.

High-pressure liquid chromatography was used to separate and compare benzo(a)pyrene activation and detoxification products in rat, mouse, and hamster hepatic microsomes and mouse and hamster embryo cell cultures. Metabolite profiles demonstrated the presence of the same type of derivatives, but marked quantitative variations were observed. Microsomal preparations produced large amounts of noncarcinogenic phenols, while intact cell metabolism favored diol formation. Metabolic diols appear to be reactivated as substrates for further activation to a more proximate carcinogenic species of benzo(a)pyrene. These results caution against extrapolating metabolic results from any single test system to other species or tissues. (31 refs)

79-6838 Alterations in the Nasal Mucosa of Syrian Golden Hamsters Exposed to Cigarette Smoke. (Eng) Basur, P. K. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario, Canada); Harada, T. *Prog Exp Tumor Res* 24: 283-301; 1979.

Syrian golden hamsters subjected for 4 wk to smoke inhalation from three types of Canadian experimental cigarettes were killed 0, 1, or 2 wk after the last smoke exposure, and the cellular response of the nasal mucosa was examined to compare the effect of these cigarettes on regenerative capacity. The incidence of acute rhinitis was greater in all smoke-exposed groups of animals killed immediately after the last exposure than in controls, and the frequency and severity of inflammation were greater in hamsters exposed to the strongest cigarette (rated on the basis of the smoke components). The inflammatory reaction was observed mainly in the respiratory region of the nasal cavity and was characterized by vacuolar degeneration and desquamation of the epithelium ac-

companied by leukocyte infiltration and increased mucous secretion. Surface morphology of the nasal mucosa of smoke-exposed hamsters was characterized by a decrease in the ciliated cell-lined zones and a widening of the squamous cell-lined zones in the anterior nasal fossa. After a 1- or 2-wk recovery period, the inflammatory changes in the smoke-exposed hamsters decreased to control levels, but the regenerated epithelium was atypical in the group exposed to smoke from the strong cigarette. The persistence of some of the cellular changes and the hyperactivity of the mucosal cells of hamsters exposed to smoke from cigarettes high in total particulate matter suggest that the degree of regenerative response may be dependent upon the extent of damage elicited by the type of cigarettes used. 79-6839 Incubation of 3,4-Benzo(a)pyrene With Serum Fractions: Effect on Tumor Production. (Eng) Stenback, F. (Dept. Pathology, Univ. Oulu, Kajaanintie 52D, SF-90220 Oulu, Finland); Curtis, G.; Rowland, J.; Ryan, W. *J Cancer Res Clin Oncol* 95(2): 109-113; 1979.

The effect of incubating 3,4-benzo(a)pyrene (BP) with mouse or rabbit serum gamma-globulin, or albumin on tumor formation in Swiss mice was investigated. BP (3.5 ml of a 25 mg/ml solution in dimethylsulfoxide) was incubated with 31.5 ml of a saline solution containing either 8 g/liter of serum, 1.16×10^{-4} mole/liter of albumin, or 5.12×10^{-5} mole/liter of gamma-globulin. Mice were injected sc with 1 ml of the incubation mixtures. A high incidence of tumors (80%-100%) was obtained with BP incubated with rabbit serum or gamma-globulin, mouse gamma-globulin, or with saline only; and a lower incidence, with BP incubated with rabbit or mouse albumin, or with mouse serum. The number of tumors developing rapidly increased, reaching a plateau after 10 wk; the tumors appeared as small, solitary, firm nodules, slowly increasing in size. Histological examination showed all the tumors to be sarcomas. These data suggest that binding of BP to serum proteins (particularly albumin) reduces its tumorigenicity. (14 refs)

79-6840 Determination of Benzo(a)pyrene in Smoked, Cooked and Toasted Food Products. (Eng) Lintas, C. (Istituto Nazionale Nutrizione, Rome, 00161, Italy); De Matthaeis, M. C.; Merli, F. *Food Cosmet Toxicol* 17(4): 325-328; 1979.

Benzo(a)pyrene content was analyzed in samples of smoked, cooked, and toasted food products as well as oils and fats commercially available in Italy. Benzo(a)pyrene was detected in approx 73% of the samples, at levels ranging from 0.01 to 9.51 $\mu\text{g}/\text{kg}$. In electrically-broiled foods, the benzo(a)pyrene content ranged from 0 to 0.05 $\mu\text{g}/\text{kg}$. Levels of benzo(a)pyrene found in the food products analyzed were lower than levels reported by other investigators for comparable food commodities. (28 refs)

79-6841 Effect of Dietary Fats on Tumorigenicity of Two Sarcoma Cell Lines. (Eng) Corwin, L. M. (Dept. Microbiology, Cancer Res. Center, Boston Univ. Sch. Medicine, Boston, MA 02118); Varshavsky-Rose, F.; Broitman, S. A. *Cancer Res* 39(11): 4350-4355; 1979.

Continuous in vitro passage in lipid-depleted media of a Kirsten sarcoma virus-transformed murine cell line (FK3T3) led to the establishment of AK3T3, a new cell line exhibiting many of the in vitro growth characteristics of the untransformed parent cell line,

BALB/3T3, A31 strain. The tumorigenicity of the AK3T3 cell line was compared with FK3T3 cells in mice fed diets varying in levels of polyunsaturated fatty acids (PUFA). Tumorigenicity of FK3T3 cells increased as the PUFA level decreased. On the other hand, tumorigenicity of AK3T3 cells decreased as dietary PUFA levels decreased. Fatty acid composition and membrane microviscosities did not differ from those of the BALB/3T3 parent strain. A correlation between tumorigenicity and cholesterol content was observed. The cholesterol levels of the FK3T3 strain were not influenced by cholesterol levels in the medium, whereas the AK3T3 and the parent BALB/3T3 cells were markedly altered, both strains having low levels when grown in delipidized media. Thus, when grown in vivo in mice fed a diet very low in PUFA and cholesterol, AK3T3 cells had lowered tumorigenicity, whereas FK3T3 cells, which can maintain their cholesterol levels under these conditions, were quite tumorigenic. AK3T3 cells were less able than FK3T3 cells to produce an immune response in vivo and to respond to specific cell-mediated cytotoxicity. It is suggested that the use of these mostly isogenic tumor strains may offer a good model system of the specific cellular alteration which affects the responses of different tumors to dietary PUFA. (24 refs)

- 79-6842 Inhibition of 2-Fluorenamine-induced Mutagenesis in *Salmonella typhimurium* by Vitamin A. (Eng) Baird, M. B. (Masonic Medical Res. Lab., Utica, NY 13503); Birnbaum, L. S. *J Natl Cancer Inst* 63(4): 1093-1096; 1979.

Retinol completely inhibited the mutagenicity of the carcinogen 2-fluorenamine (2-FA) in *Salmonella typhimurium* TA98 when the mutagen was activated by liver microsomes from CFN rats. The mutagenicity of 2-FA activated by the 9,000 x g rat liver supernatant S9 was inhibited by retinol to a lesser degree. The decline in the number of his revertants was not an artifact due to bacterial killing, inasmuch as retinol was not toxic to the bacteria at levels that totally inhibited mutagenesis by 2-FA. Mutagenesis induced by adriamycin, which does not require metabolic activation for its mutagenic potential, was unaffected by vitamin A. These results indicate that retinoids inhibit the metabolic activation of some chemical carcinogens to forms that can interact with DNA. The findings are consistent with the hypothesis that retinoids exert anticancer activity by inhibiting carcinogen activation, thereby inhibiting tumor induction, in addition to their more widely accepted role in modulating the proliferation of neoplasms derived from epithelium. (24 refs)

- 79-6843 Retinol Inhibition of Ornithine Decarboxylase Induction and G₁ Progression in Chinese Hamster Ovary Cells. (Eng) Haddox, M. K. (Dept. Pharmacology, Univ. Arizona Health Sciences Center, Tucson, AZ 85724); Scott, K. F.; Russell, D. H. *Cancer Res* 39(12): 4930-4939; 1979.

Vitamin A inhibition of ornithine decarboxylase (ODC) induction was studied in the G₁ phase of the cell cycle of synchronous Chinese hamster ovary (CHO) cell cultures. The retinol-promoted inhibition of ODC was not the result of an effect on general protein synthesis, was effective only in G₁ prior to the time an increase in ODC activity had begun, did not involve disruption of the G₁-phase increase in cyclic adenosine 3':5'-monophosphate-dependent protein kinase activity, and required transcription-dependent events for reversal. The inhibition of ODC induction was associated with a block of cell cycle progression in the G₁ phase. There was no incorporation of [³H]thymidine in the presence of the vitamin, nor was induction of S-phase-dependent

S-adenosyl-L-methionine decarboxylase or ultimate cell doubling observed. The inhibition of ODC and the inhibition of S-phase transition displayed a similar concentration dependence, with 60% inhibition occurring in the presence of 80 μ M retinol; they were also similar in their dependence on cell locus in early G₁ phase for efficacy and in a reversal after removal of the vitamin, with the increase in ODC preceding the increase in S-phase transition in a parallel fashion. Arrest of the cells at the G₁ retinol-sensitive restriction point prior to ODC induction resulted in the inhibition of the G₁-phase-dependent increase in RNA synthesis. Other naturally occurring retinoids also inhibited CHO cell growth (retinal > retinol > retinyl acetate > retinoic acid). Retinal, the most potent, displayed a paradoxical effect on CHO cells: it stimulated CHO growth parameters and ODC activity at very low concentrations (1 to 5 μ M), but at high concentrations, inhibited in a manner similar to that described for retinol. (74 refs)

- 79-6844 A Possible Naturally Occurring Tumor Promoter, Teleocidin B from *Streptomyces*. (Eng) Fujiki, H. (Natl. Cancer Center Res. Inst., 5-1-1, Tsukiji, Chuo-ku, Tokyo, Japan); Mori, M.; Nakayasu, M.; Terada, M.; Sugimura, T. *Biochem Biophys Res Commun* 90(3): 976-983; 1979.

Dihydrateleocidin B, a derivative of teleocidin B, caused marked induction of ornithine decarboxylase within 4 hr of painting on mouse skin. Induction was maximal at doses of from 5 to 7.5 μ g. Painting the skin with 13-cis-retinoic acid one hr prior to dihydrateleocidin B application inhibited this enzyme induction. Dihydrateleocidin B induced cell adhesion of human promyelocytic leukemia cells (HL-60) to the surface of culture flasks and inhibited terminal differentiation of Friend erythroleukemia cells induced by dimethyl sulfoxide. Its effective dose for these actions as compared to the potent tumor promoter 12-O-tetradecanoyl-phorbol-13-acetate (TPA) was about one fifth of that required for TPA. Teleocidin B appears to be a new type of tumor promoter. (18 refs)

- 79-6845 Influence of Vitamin A on the Laryngeal Response of Hamsters Exposed to Cigarette Smoke. (Eng) Meade, P. D. (Biomedical Sciences, Ontario Veterinary Coll., Univ. Guelph, Guelph, Ontario N1G 2W1, Canada); Yamashiro, S.; Harada, T.; Basrur, P. K. *Prog Exp Tumor Res* 24: 320-329; 1979.

The effects of vitamin A (given as a 15,000 or 25,000 IU retinyl palmitate supplement) on the latency to onset of histopathological changes in the larynx were studied in male Syrian golden hamsters exposed to long-term smoke inhalation (smoke from 8 cigarettes/day for 6 wk). The histopathological changes in the smoke-exposed hamsters supplemented with vitamin A did not differ significantly from those in the unsupplemented smoke-exposed hamsters. Liver and plasma vitamin A levels were higher in supplemented than in unsupplemented animals and were significantly lower in smoke-exposed than in sham-exposed hamsters. In hamsters maintained for 14-28 wk on a vitamin A-free diet, a moderate degree of squamous metaplasia of the surface and glandular epithelium of the larynx was noted. Similarly, the incidence of metaplasia of the laryngeal and glandular epithelium was higher in smoke-exposed hamsters maintained for 100 days on vitamin A-free diets than in smoke-exposed animals maintained on normal diets. The frequency of such histopathological changes was highest near the area of transition from stratified squamous to ciliated pseudostratified columnar epithelium. The data support the

hypothesis that animals exposed to cigarette smoke and fed a vitamin A-free diet are at higher risk of developing tumors than smoke-exposed animals given adequate vitamin A. (23 refs)

- 79-6846 Transplacental Effects of Diethylstilbestrol in Mice. (Eng) McLachlan, J. A. (Environmental Toxicology Branch, US Dept. Health, Education and Welfare, Research Triangle Park, NC 27709). *Natl Cancer Inst Monogr* (51): 67-72; 1979.

The placental transfer of (³H)- or (¹⁴C)-labeled diethylstilbestrol (DES) was studied in CD-1 mice together with the effects of prenatal DES exposure on postnatal development of genital tract function in male and female offspring. Pregnant mice received 0.01-100 µg/kg DES iv or sc on gestation days 9-16. DES-associated radioactivity in the fetal plasma approximated maternal plasma 1/2 hr after iv administration of (³H)DES; (³H)-activity associated with DES in the fetal genital tract was about threefold higher. The decrease in reproductive capacity of female offspring from mice treated with DES during gestation was dose related; a low incidence (10% or less) of cancer of the vagina, cervix, and/or uterus was also observed in these mice. Male offspring exposed prenatally to the highest dose (100 µg/kg) of DES also had lower reproductive capacities. Genital tract lesions in these mice included epididymal cysts, inflammation, cryptorchidism, and nodular masses in the seminal vesicles and/or prostate gland. Such lesions and sterility were not observed at the lower DES doses. Histologic studies suggested that müllerian duct tissue may represent a site for the transplacental toxicity of DES in both the male and female fetus. (28 refs)

- 79-6847 Synergism of Diethylstilbestrol and Radiation in Mammary Carcinogenesis in Female F344 Rats. (Eng) Holtzman, S. (Medical Dept., Brookhaven Natl. Lab., Upton, NY 11973); Stone, J. P.; Shellabarger, C. J. *J Natl Cancer Inst* 63(4): 1071-1074; 1979.

The possibility that diethylstilbestrol (DES) and radiation could act synergistically in the production of mammary tumors was investigated. One 20-mg pellet containing cholesterol only or cholesterol mixed with 0.98, 1.6, 2.6, or 3.9 mg of DES was implanted sc in each of 203 female F344 rats. Two days later, half the animals in each group were exposed to 150 R of x-rays, and the remaining animals were sham-irradiated. During the 350-day observation period, mortality was higher in groups given the higher doses of DES, with or without x-rays. Pituitary tumors and pyometritis were seen in rats given any DES dose, with or without x-ray treatment. Only rats that received both DES and x-rays developed mammary adenocarcinomas (AC). A synergistic AC response occurred in the group that received 2.6 mg DES plus x-rays; synergism was defined as a significantly greater incidence of rats with mammary tumors resulting from DES plus x-ray treatment when compared with the summed incidence from comparable individual treatments. For all other groups that received both treatments, synergism was detected only when their data were combined. Synergism was not detected among rats that had fibroadenomas (FA). Both types of neoplasms were independent phenomena, as no significant relationship was found between the incidences of FA and AC. (17 refs)

- 79-6848 Identification of Some Products from the Reaction of *Trans*-4-Aminostilbene Metabolites and Nucleic Acids

In Vivo. (Eng) Gaugler, B. J. (Institut für Pharmakologie und Toxikologie der Universität Würzburg, Versbacher Strasse 9, 8700 Würzburg, W. Germany); Neumann, H. G.; Scribner, N. K.; Scribner, J. D. *Chem Biol Interact* 27(2/3): 335-342; 1979.

Highly and specifically labeled [³H]*trans*-4-dimethylaminostilbene was prepared and administered to female Wistar rats, and the liver RNA was isolated and hydrolyzed. The hydrolysate was chromatographed and a series of nucleoside adducts was obtained. Identification between labeled in vivo and unlabeled in vitro adducts was accomplished. 1-(4-Acetamidophenyl)-1-(3-uridylyl)-2-hydroxy-2-phenylethane, 1-(4-acetamidophenyl)-1-(1-guanosyl)-2-hydroxy-2-phenylethane, 3-(β-D-ribose)-7-phenyl-8-(4-acetamidophenyl)-7,8-dihydroimidazo-[2,1-i]-purine, and a guanosyl-O⁶ derivative were formed in vivo when the carcinogen *trans*-4-dimethylaminostilbene was administered po to the female rats. Upon hydrolysis, rat-liver RNA released 1-(4-acetamidophenyl)-2-phenyl-1,2-ethanediol. Comparison of the adduct patterns resulting from the reaction of N-acetoxy-N-acetylaminostilbene with yeast RNA in vitro with those obtained from the same reaction with in vitro rat liver RNA revealed both quantitative and qualitative differences. This indicated that reactive metabolites other than hydroxamic acid esters may have contributed to the in vivo binding. (10 refs)

- 79-6849 The Effects of Sex Hormones on the Development of Urinary Bladder Tumors Induced by N-Butyl-N-(4-Hydroxybutyl) Nitrosamine in Rats. (Jpn) Iriya, K. (Dept. Urology, Nara Medical Univ., Kashiwara City, Nara Pref. 634, Japan). *Nara Igaku Zasshi* 30(1/2): 69-82; 1979.

The effects of diethylstilbestrol and testosterone on the development and growth of N-butyl-N-(4-hydroxybutyl) nitrosamine (BBN)-induced urinary bladder tumors in 129 male and 120 female 10-wk-old Wistar rats were studied. Rats received 0.05% BBN po in drinking water for 6 wk followed by a BBN-free diet for 18 wk and then sacrificed. Before (1 wk) or after BBN administration, orchiectomized or intact male rats received 50-mg diethylstilbestrol sc pellet implants; ovariectomized or intact females received 50-mg testosterone sc pellet implants. Bladder tumors developed in 6/10 male and 2/11 female control rats. In male rats given BBN 1 wk after implantation of diethylstilbestrol alone or those that received diethylstilbestrol and underwent orchiectomy, the incidence of tumors was 1/14 and 0/12 respectively, while tumors occurred in 5/12 rats that underwent orchiectomy alone. The incidence of tumors in male rats given diethylstilbestrol implants (without or with orchiectomy) after 6 wk of BBN was 1/17 and 1/12, and that in rats given orchiectomy alone after BBN treatment was 4/11. The incidence of tumors in female rats given testosterone, testosterone plus ovariectomy, or ovariectomy 1 wk before BBN administration was 4/11, 5/10, and 4/11, respectively, and the incidences in rats given testosterone alone, testosterone plus ovariectomy, or ovariectomy alone were 6/11, 8/11, and 6/11. The results indicate that orchiectomy had no influence on inhibition of carcinogenesis, that diethylstilbestrol inhibited carcinogenesis and the growth of tumors in male rats, that testosterone promoted the growth of bladder tumors in female rats, and that there was a higher incidence of BBN-induced urinary bladder tumors in male than in female rats. (33 refs)

- 79-6850 Effects of Transplacental Exposure to Diethylstilbestrol on Carcinogenic Susceptibility During Postnatal Life in Hamster Progeny. (Eng) Rustia, M. (Eppley Inst.

Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE 68105); Shubik, P. *Cancer Res* 39(11): 4636-4644; 1979.

Prenatal exposure to a single dose of diethylstilbestrol (DES) produced a significant increase in carcinogenic response of hamster progeny that were subsequently subjected to the carcinogenic stimulus of 7,12-dimethylbenz(a)anthracene (DMBA) during postnatal life. Pregnant Syrian golden hamsters received a single dose of DES, 10 mg/kg, on day 14 of gestation. Postnatally, at 6 wk of age, the progeny were given DMBA, 25 mg/kg po twice/wk for 8 wk. The second group (not exposed in utero to DES) received DMBA at 6 wk of age, 30 mg/kg po, twice/wk for 18 wk. The progeny exposed to DES prenatally and DMBA postnatally developed a greater multiplicity of tumors per tumor-bearing animal ($p < 0.001$) and higher rates of neoplasms of the reproductive tract (ovarian and uterine), mammary gland, and forestomach, as well as of dermal melanomas. The prenatally DES-exposed progeny also had significantly higher incidences of malignant tumors, eg carcinomas of the mammary gland ($p < 0.001$) and carcinomas of the forestomach ($p < 0.001$), than did the hamsters given DMBA alone. Endocrine imbalance produced by exposure in utero may heighten the sensitivity of the progeny to development of neoplasms after a challenge with carcinogenic stimuli in adult life. The relevance of these experimental data to the human situation is discussed. (47 refs)

79-6851 Diethylstilbestrol: Evidence for Metabolic Activation in Man, Rat, and Hamster. (Eng) Metzler, M. (Institut für Pharmakologie und Toxikologie, Universität Würzburg, Versbacher Landstrasse 9, W. Germany). *Natl Cancer Inst Monogr* (51): 73-76; 1979.

Male and female Wistar rats (200-250 g), male Syrian golden hamsters (150-200 g), and two male human volunteers (aged 41 and 32 yr) were given radioactive diethylstilbestrol (DES) and metabolites extracted from urine and bile were analyzed. Urinary and biliary radioactivity was predominantly (60%-80%) associated with glucuronides. Two of the major biliary metabolites for rats and hamsters were mono- and dimethoxy-DES. The two methoxy groups in dimethoxy-DES were attached to different aromatic rings. Dienestrol was present in both bile and urine from these animals. The major urinary DES metabolites in rats and hamsters were ω -hydroxy-DES, methoxydienestrol, and ω -hydroxydienestrol. A cleavage product of DES, migrating with 4'-hydroxypropeophenone in chromatographic separation, represented a major urinary metabolite in male rats. In the human males, glucuronides, comprising 80%-90% of the urinary radioactivity, contained DES, dienestrol, and ω -hydroxydienestrol. Fecal material contained about 30% of the dose; almost all was unconjugated material. Only DES could be identified in fecal extracts. The 24-hr urine of a woman breast cancer patient treated with unlabeled DES showed DES, dienestrol, and hydroxydienestrol. Thus, at least seven DES metabolites are formed in vivo, some of which are potentially reactive. (23 refs)

79-6852 Developmental Mechanism of Estrogen-induced Irreversible Changes in the Mouse Cervicovaginal Epithelium. (Eng) Forsberg, J. G. (Inst. Anatomy, Univ. Bergen, Arstadveien 19, 5000 Bergen, Norway). *Natl Cancer Inst Monogr* (51): 41-56; 1979.

Neonatal female NMRI mice were inoculated sc with 5 μ g/day of 17 β -estradiol or diethylstilbestrol (DES) and were studied with

respect to the immediate and long-term effects of estrogen exposure on the cervicovaginal epithelium. The estrogens inhibited proliferation of the pseudostratified columnar epithelium in the upper part of the müllerian vagina. This resulted in the occurrence of regions containing a columnar epithelium (CE) in the uterine cervix and upper vagina of adult animals instead of the normal squamous epithelium. Later, the CE developed into adenosis; subsequently, suspected malignant changes were seen. In addition to these morphologic changes, neonatal estrogen treatment resulted in changes in the amount of cervicovaginal antigenic (CVA) material. Compared with control levels, CVA titers were high in the superficial mucified vaginal cells of neonatally DES-treated mice that were subsequently castrated and given estrogen as adults. The CE had a low level of CVA. An interaction between estradiol and prolactin was important for the CVA level; neonatal estrogen treatment may result in persistent changes in the regulation of plasma prolactin. A comparison is made between the estrogen-induced changes in mice and the effects of DES in the female offspring of women exposed to DES during pregnancy. The importance of the mouse model for the study of the estrogen-induced changes and other factors influencing the development of human clear cell adenocarcinomas of the vagina and cervix is stressed. (78 refs)

79-6853 Development of Permanently Proliferated and Cornified Vaginal Epithelium in Mice Treated Neonatally with Steroid Hormones and the Implication in Tumorigenesis. (Eng) Takasugi, N. (Dept. Biology, Faculty Science, Okayama Univ., Tsushima, Okayama 700, Japan). *Natl Cancer Inst Monogr* (51): 57-66; 1979.

Five to ten daily injections of 5-20 μ g 17 β -estradiol, 20-100 μ g testosterone and its propionate, and 100 μ g 5 α -dihydrotestosterone, starting within 24 hr of birth, caused persistent proliferation and cornification of the vaginal epithelium in female C57BL/Tw, C57BL/Ms, A/Ms, and A/Crgl mice. The cornification was independent of endogenous estrogen, and hyperplastic lesions were frequent in the altered vaginal epithelium. In C57BL/Tw mice, some undifferentiated cells, which survive only a few days postnatally in normal animals, appeared to transform into large cells and formed nodules after neonatal administration of 17 β -estradiol. The primary normal epithelium was replaced by a sheet of fused nodules that showed persistent proliferation and cornification independent of estrogen. The occurrence of the estrogen-independent vaginal cornification in C57BL mice receiving neonatal injections of 20 μ g estradiol for 5 days was prevented by injections of vitamin A acetate (200 IU) when given simultaneously with the estradiol. Light cells (ie, cells with reduced cytoplasmic electron density) were found by electron microscopy in the epithelium of mice treated with estradiol + vitamin. These cells may be significant in degeneration of permanently changed vaginal epithelium. (39 refs)

79-6854 The Occurrence of Adenocarcinoma in Endometriosis of the Rectovaginal Septum During Progestational Therapy. (Eng) Addison, W. A. (Dept. Obstetrics and Gynecology, Duke Univ. Medical Center, Box 3296, Durham, NC 27710); Hammond, C. B.; Parker, R. T. *Gynecol Oncol* 8(2): 193-197; 1979.

The case report of a patient who developed adenocarcinoma in endometriosis of the rectovaginal septum during a second course of hormonal therapy is presented. The patient presented at the age of

37 with rectal and vaginal bleeding due to endometriosis. Pelvic examination revealed a mobile, rubbery mass approx 5 x 5 x 6 cm occupying the rectovaginal septum. The symptoms resolved promptly upon induction of pseudopregnancy with Enovid (20 mg/day). This was discontinued after 9 mo due to weight gain, fluid retention, and elevated blood pressure. The symptoms returned after 6 mo and the patient was treated with im Depo-Provera (200 mg/wk x 4, followed by 200 mg/mo). There was an initial response, but after 3 mo of therapy, the mass was significantly enlarged. A biopsy taken from the same area as previous biopsies showing endometriosis now showed adenocarcinoma. The patient died of abdominal carcinomatosis, despite chemotherapy. Twelve cases of primary adenocarcinoma arising in areas of endometriosis in the rectovaginal septum have been reported. Malignant transformation in an area of endometriosis during sex steroid therapy has not been reported previously. (8 refs)

- 79-6855 The Histology of Liver Tumors in Oral Contraceptive Users Observed During A National Survey by the American College of Surgeons Commission on Cancer. (Eng) Nime, F. (Dept. Pathology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263); Pickren, J. W.; Vana, J.; Aronoff, B. L.; Baker, H. W.; Murphy, G. P. *Cancer* 44(4): 1481-1489; 1979.

As part of the national survey on the tumorigenesis of oral contraceptives conducted by the American College of Surgeons' Commission on Cancer, 94 cases of liver tumors in oral contraceptive users and non-users were studied histologically. Pathologic criteria were established prior to studying the slides; the results were then tabulated to determine the significance of each of the criteria as related to the use of contraceptives. These criteria included tumor size and the presence or degree of peliosis hepatis, hemorrhage, necrosis, fibrosis, thrombosis, or vascular alterations of the intima and media. Livers showing focal nodular hyperplasia in pill users exhibited greater vascular alterations, fibrosis, peliosis, and tumor size compared with livers showing focal nodular hyperplasia from non-pill users. Hemorrhage, necrosis, and peliosis were much more common in liver cell adenoma than in focal nodular hyperplasia. In the material reported in this series, there were no cases of liver cell adenoma among non-pill users. The livers showing focal nodular hyperplasia exhibited an overwhelmingly greater degree of vascular intimal and medial alterations than did those showing liver cell adenoma. The results suggest that oral contraceptives primarily affect the liver vasculature. (19 refs)

- 79-6856 Sister-Chromatid Exchanges in Oral Contraceptive Users. (Eng) Murthy, P. B. (Natl. Inst. Nutrition, Indian Council Medical Res., Jamai Osmania P.O., Hyderabad-500 007, India); Prema, K. *Mutat Res* 68(2): 149-152; 1979.

The frequencies of sister-chromatid exchanges (SCE) in the peripheral lymphocytes of 15 nonpregnant women, 15 women in the third trimester of pregnancy, and 15 women who had been taking oral contraceptives (OC, 150 µg *d*-norgestrel and 30 or 50 µg ethinyl estradiol/day) for 6-24 mo (mean 16 mo) were determined. The women ranged in age from 18 to 35 yr (mean 23.6 yr). The mean number of SCE/cell was significantly higher in the OC users (9.7) than in the pregnant controls (5.8) and nonpregnant controls (6.3). This increase was observed in most OC users. The results indicate the existence of an increased mutagenic environment in the peripheral lymphocytes of OC users; this environment is caused by either the OC itself or by a metabolite(s). (12 refs)

- 79-6857 Effects of Progesterone and R2323 on the Development of Dimethylbenzanthracene-induced Mammary Tumors. (Eng) Kelly, P. A. (Medical Res. Council Group in Molecular Endocrinology, Le Centre Hospitalier de l'Université Laval, Quebec G1V 4G2, Canada); Asselin, J.; Turcot-Lemay, L.; Labrie, F.; Raynaud, J. P. *Eur J Cancer* 15(10): 1243-1251; 1979.

Progesterone (PRG: 0.5 or 4.0 mg/day, sc) or the antiprogesterin 13 α -ethyl-17-hydroxy-18, 19-dinor-17 β -pregna-4, 9, 11-triene-20-yn-3-one (R2323: 2.5-150 µg/day, sc) was given to female Sprague-Dawley rats (50-55 days old), beginning the day after iv injection of 7,12-dimethylbenz(a)anthracene (DMBA: 5 mg/rat). Mammary tumor development was followed for 133-141 days after DMBA treatment. Both doses of PRG promoted early mammary tumor growth, although the max tumor prevalence and the max number of tumors/rat (measured on day 141) were similar to control values. At the lower PRG dose, the tumors were much larger than those in vehicle-treated controls, and tumor estradiol (E2) binding was increased slightly. The higher PRG dose reduced tumor binding of R5020 (17,21-dimethyl-19-nor-pregna-4, 9-diene-3-dione). Both doses of PRG caused a significant reduction in plasma luteinizing hormone (LH) levels, but they did not affect plasma prolactin (PRL) levels or tumor PRL binding. R2323 caused a dose-related inhibition of tumor development and a marked reduction in plasma LH, but it had no significant effect on plasma PRL levels or tumor levels of E2, PRG, or PRL receptors (compared with control tumors). This inhibition of gonadotropin secretion might be mainly responsible for the marked antitumor activity of R2323, although part of the inhibitory effect might be exerted directly at the tumor level. (32 refs)

- 79-6858 Effect of Pituitary Isografts on the Concentration of Estrogen and Glucocorticoid Receptors in C3H Mice Mammary Tumors. (Eng) Coezy, E. (Unité 148 de l'Inserm, 60, rue de Navacelles, 34100 Montpellier, France); Rochefort, H. *Eur J Cancer* 15(10): 1185-1189; 1979.

The effects of pituitary isografts on the induction and steroid receptor levels of mammary tumors were investigated in C3H mice. The latent period of tumorigenesis was shortened, but the final tumor incidence was unaffected. Pituitary grafting resulted in a threefold increase in the concentration of cytosol estrogen receptor sites in the tumors when measured 1 day after ovariectomy; however, the affinity of the receptor for estradiol was not modified. In contrast, glucocorticoid receptor levels were not increased, and the progesterone receptor concentration was negligible with or without pituitary grafts. The sustained high prolactin levels in the mice grafted with pituitaries are probably responsible for the increase in the estrogen receptor site concentration. The authors propose that the stimulating effect of prolactin on mammary tumor induction might not only be due to the activation of prolactin receptors but also to the accumulation of the estrogen receptor, resulting in local hypersensitivity to estrogens. - 79-6859 Formation and Removal of Aflatoxin B₁-induced DNA Lesions in Epithelioid Human Lung Cells. (Eng) Wang, T. V. (Dept. Carcinogenesis, Swiss Inst. for Experimental Cancer Res., CH-1066 Epalinges-Lausanne, Switzerland); Cerutti, P. A. *Cancer Res* 39(12): 5165-5170; 1979.

The formation and removal of covalent aflatoxin B₁ (AFB)₁:DNA adducts under nontoxic conditions were studied in metabolically active epithelioid human lung cells (A549). After 24 hr exposure to

0.82 μM AFB₁, the adduct level was in the range of 0.16 to 1.34 $\mu\text{moles adduct/mole DNA-phosphate}$. Approx 60% of the total initial AFB₁ adducts were removed rapidly during the first 24 hr of posttreatment incubation of A549 cells, while only 15% of the total adducts were released from free AFB₁:DNA isolated from A549 cells within the same time period under physiological conditions *in vitro*. The remaining 40% of the adducts were removed very slowly, leaving a sizable fraction of residual lesions in the DNA over several generation times. Of three products distinguishable by Sephadex LH 20 and high-pressure liquid chromatography in formic acid hydrolysates of DNA from A549 cells immediately following AFB₁ treatment, 2,3-dihydro-2-(N'-guanyl)-3-hydroxyafatoxin B₁ was predominant (42%-64%). The disappearance of lesions assayed as this product in acid hydrolysates of DNA was rapid and occurred with similar kinetics upon incubation of intact cells in culture or of free DNA *in vitro* under physiological conditions. For free AFB₁:DNA, the disappearance of these lesions is in part due to their transformation to more stable secondary derivatives which remain attached to the DNA backbone. As with the *in vitro* situation, it is likely that a portion of the primary lesions in A549 cells are also first modified either spontaneously or enzymatically to secondary lesions which are then processed by the cellular repair pathways. (18 refs)

79-6860 Promotion of Azoxymethane-induced Intestinal Cancer by High-Fat Diet in Rats. (Eng) Bull, A. W. (Dept. Surgery, Wayne State Univ. Sch. Medicine, Detroit, MI 48201); Soullier, B. K.; Wilson, P. S.; Tan Hayden, M. T.; Nigro, N. D. *Cancer Res* 39(12): 4956-4959; 1979.

Promotion of intestinal cancer by a high-fat diet was studied by feeding a 30% beef diet to 8 groups of rats (25 rats/group) for time periods varying from 1 to 21 wk after 8 weekly sc injections of azoxymethane (AOM, 8 mg/kg). Two other groups were fed the high-fat diet, one for 8 wk prior to and the other during AOM injections. A 5% fat diet was fed to rats when not on the 30% fat diet and to a control group of 25 animals. The high-fat diet increased intestinal tumor frequency as much as twofold when given for at least 4 wk after but not during or prior to AOM injections; this increase occurred even after a prolonged interval (10 wk) between the last AOM injection and the high-fat diet. In general, tumor frequency increased according to the length of time animals were fed the high-fat diet after AOM. The high-fat diet in this model exhibited most of the properties of promoters of murine skin cancer. These results support the concept that excess dietary fat acts at the promotional phase of carcinogenesis. (15 refs)

79-6861 Tumorigenicity of Bay-Region Epoxides and Other Derivatives of Chrysene and Phenanthrene in Newborn Mice. (Eng) Buening, M. K. (Dept. Biochemistry, Hoffmann-La Roche, Inc., Nutley, NJ 07110); Levin, W.; Karle, J. M.; Yagi, H.; Jerina, D. M.; Conney, A. H. *Cancer Res* 39(12): 5063-5068; 1979.

The tumorigenic activity of the bay-region diol-epoxides and tetrahydroepoxides of chrysene and phenanthrene was tested in newborn Swiss-Webster mice. The test compounds were given on the 1st, 8th, and 15th days of life (0.2, 0.4, and 0.8 $\mu\text{mol ip}$, respectively) and the animals were observed until they were 38-42 wk old. (\pm)-1 β ,2 α -Dihydroxy-3 α ,4 α -epoxy-1,2,3,4-tetrahydrochrysene, in which the epoxide is *trans* to the benzylic 1-hydroxyl group was the most tumorigenic chrysene derivative tested, producing pulmonary

tumors in 98% of the mice, with an av of 15.9 tumors/mouse. (\pm)-1 β ,2 α -Dihydroxy-3 β ,4 β -epoxy-1,2,3,4-tetrahydrochrysene, in which the bay region epoxide oxygen is *cis* to the benzylic 1-hydroxyl group, had little tumorigenic activity. *trans*-2-Dihydroxy-1,2-dihydrochrysene and 1,2-dihydrochrysene and 1,2-dihydrochrysene, the immediate metabolic precursors of a bay-region diol-epoxide and a bay-region tetrahydroepoxide, respectively, were the next most active chrysene derivatives tested. They produced pulmonary tumors in 73%-75% of the mice, with an av of 2.1-2.2 tumors/mouse. 3,4-Epoxy-1,2,3,4-tetrahydrochrysene (bay-region epoxide) induced pulmonary tumors in 71% of the mice, with an av of 1.26 tumors/mouse. Other chrysene derivatives tested had little or no tumorigenic activity. Chrysene had little tumorigenic activity in the lung but induced liver tumors in 25% of the mice. The bay-region tetrahydroepoxide, 3,4-epoxy-1,2,3,4-tetrahydrophenanthrene, induced pulmonary tumors in 45% of the mice, with an av of 0.74 tumors/mouse. Phenanthrene and its other derivatives tested had little tumorigenic activity. It is concluded that the carcinogenicity of chrysene follows the predictions of the bay-region theory. The small size and resulting increased polarity of the phenanthrene diol-epoxides and tetrahydroepoxides may limit their intrinsic activity. (25 refs)

79-6862 Formation and Subsequent Excision of O⁶-Ethylguanine from DNA of Rat Liver Following Administration of Diethylnitrosamine. (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, Hershey, PA 17033); Balog, B. *Cancer Res* 39(12): 5003-5009; 1979.

The alkylation of rat liver DNA was studied at short times after ip injection of low (0.5-4 mg/kg) and high (10-100 mg/kg) doses of diethylnitrosamine (DEN). Ethylation of DNA, measured by the production of 7-ethylguanine, was almost complete within 30 min after the 0.5-mg/kg dose of DEN, within 90 min after 2 mg/kg, and within 120 min after 4 mg/kg. O⁶-ethylguanine levels decreased by 33% between 30 and 120 min after the injection of 0.5 mg/kg DEN. A loss of O⁶-ethylguanine also occurred from liver DNA shortly after 2- and 4-mg/kg doses of DEN. A ratio of O⁶-ethylguanine:7-ethylguanine in the ethylated DNA close to 0.71 (the value found by reaction of DNA *in vitro* with N-ethyl-N-nitrosourea) was found only at the earliest times measured or only after doses ≥ 10 mg/kg. This suggests that the higher O⁶-ethylguanine:7-ethylguanine ratio observed at higher DEN exposures is due to rapid excision of O⁶-ethylguanine from the DNA. The half-life of O⁶-ethylguanine and O⁶-methylguanine from 1.4-0.1 $\mu\text{mol/mol guanine}$ was 1.5-3 hr and the max rate of removal was 1.5 $\mu\text{mol/mol guanine/hr}$. Comparisons of losses in the range 14-8 $\mu\text{mol/mol guanine}$ showed half-lives of 6-8 hr and removal rates of 1.5 $\mu\text{mol/mol guanine/hr}$. A cell-free extract that specifically catalyzed the removal of O⁶-ethylguanine from DNA was isolated from rat liver. The same preparation produced approx equal rates of O⁶-methylguanine removal from methylated DNA and O⁶-ethylguanine removal from ethylated DNA when the substrate concentrations were similar. The rapid repair observed in these studies may be important in limiting the potential for neoplastic change after exposure to low dietary levels of these carcinogens. (36 refs)

79-6863 Effect of Age at Treatment on Incidence and Type of Renal Neoplasm Induced in the Rat by a Single Dose of Dimethylnitrosamine. (Eng) Hard, G. C. (Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA 19140). *Cancer Res* 39(12): 4965-4970; 1979.

Groups of Porton albino Wistar rats received a single ip injection (30 mg/kg body wt) of dimethylnitrosamine at 24 hr; at 3 wk; and at 1, 1.5, 2, 3, 4, and 5 mo of age. In all groups except the neonates, the animals were preconditioned by feeding a no-protein, high-carbohydrate diet for 5 days prior to carcinogen injection. In the neonatal group, the dose of carcinogen had to be reduced to 20 mg/kg in order to achieve approx equivalent numbers of survivors. Notwithstanding the loss of strict comparability of data between the newborns and the remaining age groups, kidney tumor incidence showed a bimodal distribution represented by the occurrence of two separate entities, renal mesenchymal tumor and cortical epithelial tumor. Mesenchymal tumor proved to be a neoplasm of the neonatal and immature rat; susceptibility to this tumor fell rapidly after 1 mo of age to nil at 5 mo of age. Susceptibility to tumors of cortical tubule epithelium increased with ensuing sexual maturity but declined by 5 mo of age. Age at dosing also influenced to some degree the grade of tumor induced. An altered grade of mesenchymal tumor was illustrated by the emergence in older age groups of a fibroma-like variant not encountered in earlier groups while epithelial tumors graded as carcinomas were not induced in rats dosed at 5 mo of age. The adenomas in the latter group also presented a less active appearance than did equivalent lesions in earlier groups. No renal lipomatous tumors were seen among the 100 mesenchymal neoplasms induced in this study, but a single lesion consistent with an early nephroblastoma was found in one rat dosed at birth. The exclusive occurrence of two predominant types of kidney tumor indicates the specificity of the host-tumor interaction elicited by dimethylnitrosamine. (24 refs)

- 79-6864 Lack of Proportionality Between Rate of Cell Division and Induction of Tumors in Carcinogen-exposed Regenerating Livers. (Eng) Becker, F. F. (Dept. Pathology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Cancer Res* 39(12): 5177-5178; 1979.

Male CFE Sprague-Dawley rats underwent 70% hepatectomy at 55 or 175 g body wt, and the course of DNA synthesis of the first responsive wave of cell division was determined by [³H]thymidine incorporation and DNA analysis. Peak DNA synthesis occurred at the 20th-22nd hr for the younger rats and at the 24th-26th hr for the older ones. The specific activity of the older rats was 2.5 times greater than that of the older ones at peak synthesis. Dimethylnitrosamine (DMN: 10 mg/kg, ip) was administered to the older rats 24 hr after partial hepatectomy and at 6, 20, and 30 hr after surgery (9 mg/kg, ip) in the 55-g rats. 7,12-Dimethylbenz(a)anthracene (DMBA: 20 mg/kg, ip) and N-hydroxyacetylaminofluorene (40 mg/kg, ip) were given only to the younger rats at 6, 20, and 30 hr after operation. The animals were observed until they were 2 yr old. Primary hepatocellular carcinoma (PHC) was identified in 2/22 older rats treated with DMN and in 2/18 and 3/18 younger rats given DMN at 20 and 30 hr, respectively. PHC was not detected in any of the other rats. In these experiments, the use of the young rat, with its greatly increased amplitude and synchrony of DNA synthesis, did not commensurately increase the yield of carcinoma nor shorten the lag time significantly. These results suggest that carcinogen administration during cell division is not in itself sufficient to give a high yield of tumors. The results also suggest that the post-S period might be even more susceptible to DMN than the S phase. (14 refs)

- 79-6865 Correlation of DNA Methylation by Methyl(acetoxymethyl)nitrosamine with Organ-specific Car-

cinogenicity in Rats. (Eng) Kleihues, P. (Abteilung Neuropathologie, Pathologisches Institut der Universität, 78 Freiburg, W. Germany); Doerjier, G.; Keefer, L. K.; Rice, J. M.; Roller, P. P.; Hodgson, R. M. *Cancer Res* 39(12): 5136-5140; 1979.

Male Sprague-Dawley (Charles River CD) rats received a single iv or ip injection (12 mg/kg) of the α -acetoxymethyl derivative of dimethylnitrosamine, *N*-[¹⁴C]methyl-*N*-acetoxymethylnitrosamine (MAMN), and were killed after 12 hr. Following iv injection, highest concentrations of 7-methylguanine and O⁶-methylguanine were present in DNA of the lung, the principal target organ in MAMN carcinogenesis at this dosage by this route of application. Ip injection led to preferential DNA alkylation in organs bordering the abdominal cavity, with highest levels of methylated purines in the ileum and colon, the principal sites of tumorigenesis for this route of administration. Esterases potentially responsible for the bioactivation of MAMN in vivo were found in all organs investigated, with the highest levels of activity located in rat kidney and liver. Incubation of MAMN with DNA and esterases from rat kidney in vitro resulted in a pattern of methylated purines similar to that produced by *N*-methyl-*N*-nitrosourea and related methylating carcinogens; these agents, including dimethylnitrosamine, thus appear to exert their biological effects through a common alkylating intermediate. Pretreatment of rat liver extracts with the esterase inhibitor diisopropyl fluorophosphate (10⁻⁴ M) reduced both the decomposition of MAMN and DNA alkylation in vitro by more than 90%. (34 refs)

- 79-6866 Establishment of a Cell Culture Line from a Transplantable Rat Stomach Cancer Induced by *N*-Methyl-*N'*-nitro-*N*-nitrosoguanidine. (Eng) Kobori, O. (First Dept. Surgery, Faculty Medicine, Univ. Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113, Japan); Martin, F.; Martin, M.; Turc, C. *Cancer Res* 39(12): 5141-5146; 1979.

A cell line, termed BV9, was cultured from a transplantable rat stomach cancer originally induced in the glandular stomach of a Wistar rat by po administration of *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine. The monolayer cells, subcultured for more than 35 passages, revealed pleomorphic features. Chromosomal analysis showed hypertetraploidy (mode, 95), and marker chromosomes were present. Cultured cells were injected sc into cyclophosphamide-conditioned syngeneic rats and produced tubular adenocarcinomas resembling the original tumor. (24 refs)

- 79-6867 Mutagenicity of *N*-Methyl-*N'*-aryl-*N*-nitrosoureas and *N*-Methyl-*N'*-aryl-*N'*-methyl-*N*-nitrosoureas in Relation to Their Alkylating Activity. (Eng) Yano, K. (Dept. Chemistry, Saitama Medical Sch., 981 Kawakado, Moroyama, Iruma-gun, Saitama 350-04, Japan); Isobe, M. *Cancer Res* 39(12): 5147-5149; 1979.

The mutagenic activities of a series of *N*-methyl-*N'*-aryl-*N*-nitrosoureas (MANU) and *N*-methyl-*N'*-aryl-*N'*-methyl-*N*-nitrosoureas (MAMNU) were investigated in *Salmonella typhimurium* strain TA 1535. All MANU compounds had strong mutagenic potency without metabolic activation, and their effectiveness was even greater than that of *N*-methyl-*N*-nitrosourea. The mutagenicity at a given concentration of the compounds (3.35 $\times 10^{-2}$ μ mole) was compared with the chemical alkylating activity with 4-(*p*-nitrobenzyl)pyridine. A positive parallelism was observed in the cases of *N*-methyl-*N'*-(*p*-methoxyphenyl)-*N*-nitro-

sourea, *N*-methyl-*N'*-(*p*-methylphenyl)-*N*-nitrosourea, *N*-methyl-*N'*-phenyl-*N*-nitrosourea, and *N*-methyl-*N'*-(*p*-chlorophenyl)-*N*-nitrosourea, whereas this correlation broke down with *N*-methyl-*N'*-(*p*-acetylphenyl)-*N*-nitrosourea and *N*-methyl-*N'*-(*p*-nitrophenyl)-*N*-nitrosourea. These observations are discussed in terms of both the inductive effect and hydrogen-bonding nature of the substituents and the difference in the chemical and biologic processes. The MAMNU compounds, which are the methyl-substituted derivatives on the second nitrogen (*N'*), had no significant or weaker mutagenicity when compared to the corresponding MANU compounds; this result was also in agreement with the results of the chemical alkylation. The dose-response curves for the two classes of derivatives showed that all mutagenicities, except in the case of *N*-methyl-*N'*-phenyl-*N'*-methyl-*N*-nitrosourea, increased similarly in accordance with an increase in their concentrations, indicating that the lethal effect might not influence the observed mutagenicity. Mechanistically, it has been suggested that removal of the hydrogen on *N'* may be involved in the transition state of both the chemical and mutagenic actions of the MANU compounds. With the MAMNU compounds, however, further investigations are needed to elucidate the observed results; other factors, such as inductive and steric effects by the methyl group on *N'*, may also be of importance in their case. (25 refs)

79-6868 Kidney Tumors Induced in Rats by the Antischistosomal Drug Niridazole. (Eng) Bulay, O. (Epilepsy Inst. Res. Cancer, Univ. Nebraska Medical Center, Omaha, NE 68105); Patil, K.; Wilson, R.; Shubik, P. *Cancer Res* 39(12): 4996-5002; 1979.

The induction of renal tumors by the antischistosomal drug niridazole observed in MRC rats was studied. Rats aged 6 to 8 wk were fed niridazole in the diet at four dosage levels: 0.1% (Group 1); 0.05% (Group 2); 0.025% (Group 3); 0.0125% (Group 4); and 0% (Group 5). The rats were allowed to die spontaneously and were autopsied. The life span of Group 1 was shortened by the tox-

ic effects of niridazole, whereas the animals given lower concentrations lived longer. The main target tissue was the kidneys, with tumors developing in this organ in 9/60 animals in Group 1, in 34/58 in Group 2, in 34/59 in Group 3, and in 30/60 in Group 4. Forestomach tumors occurred in a slightly higher incidence than in controls, while the incidences of other lesions were similar to those occurring spontaneously in control rats. Histologically, epithelial tumors were adenomas and adenocarcinomas comprising solid papillary, clear cell, and tubular types, with the latter type predominating. Seven mesenchymal tumors were found among the 107 renal epithelial neoplasms. High frequencies of severe nephrosclerosis occurred in both treated and control rats, but the extent and severity of nephrosclerotic changes were greater in the treated rats and appeared significantly earlier. This study indicates that nephrosclerosis plays a cofactor role in the experimentally induced kidney tumors and that continuous carcinogen administration is necessary to initiate kidney tumors. PHYSICAL CARCINOGENESIS

- 79-6869 Analysis of Dose-Response Patterns in Mutation Research. (Eng) Haynes, R. H. (Dept. Biology, York Univ., Toronto, Ontario M3J 1P3, Canada); Eckardt, F. *Can J Genet Cytol* 21(3): 277-302; 1979.

Stochastic assumptions were used to derive formal expressions for induced mutagenesis, and the Poisson distribution was used to analyze UV-induced forward and reverse mutations in haploid strains of the yeast *Saccharomyces cerevisiae*. The mutation yield (mutants per cell treated) and cell survival should be reported independently, as such data are of more value in mutation research than curves showing mutation frequency (mutants per survivor) only. Mutation yields, and in particular the position and magnitude of max yields, should be measured as carefully as possible as a means of verifying the apparent pattern of mutation induction kinetics suggested by double-logarithmic plots of mutation frequencies. For purely linear processes of mutation induction and exponential survival, the max mutant yield is known to occur as the LD₃₇ dose. However, for nonlinear kinetic patterns, the position and magnitude of the max yield shifts away from the LD₃₇ in mathematically predictable ways. For any given pattern of killing and mutation, the ratio of the max mutant yields plotted over lethal hit units for two mutagens is a convenient measure of their relative mutagenic efficiencies. (40 refs)

- 79-6870 Enhancement of Excision-Repair Efficiency by Conditioned Medium from Density-inhibited Cultures in V79 Chinese Hamster Cells. Evidence for Excision Repair as an Error-free Repair Process. (Eng) Nakano, S. (First Dept. Medicine, Kyushu Univ. Sch. Medicine, Fukuoka 812, Japan); Yamagami, H.; Takaki, R. *Mutat Res* 62(2): 369-381; 1979.

The effect of conditioned medium (CM) from density-inhibited cultures on UV-induced cell killing, mutation frequency, and the rate of DNA synthesis was studied using V79 Chinese hamster cells. CM from stationary-phase cultures did not influence the cloning efficiency of unirradiated cells, although cell growth was retarded and colony size reduced. CM significantly reduced the lethal effect of UV light ($p < 0.01$), a max increase in cell survival being observed with medium conditioned for 1 day. There was a continuous increase in cell survival with increasing exposure to CM up to 18 hr, after which the rate plateaued. The increase in cell survival was mediated by a repair mechanism other than caffeine-sensitive postreplication repair. In normal medium, the rate of DNA synthesis in normal cells increased exponentially, whereas in CM it was significantly suppressed. Similar results were obtained with UV-irradiated cells, except that DNA synthesis recovered 3-4 hr after irradiation. S-phase nuclei in normal medium were heavily labeled with [³H]thymidine, whereas those in CM showed relatively little labeling. The reduction in the fraction of S-phase cells could reflect a reduced rate of ongoing DNA synthesis in these cells. CM did not influence the spontaneous mutation frequency of V79 cells, and at equicytotoxic doses of UV, mutation frequencies in CM-treated cells were equal to the frequency in untreated cells. The data suggest that CM potentiates an error-free excision repair process, leaving fewer lesions available for error-prone postreplication repair. (42 refs)

- 79-6871 Photodynamic Cytotoxicity of Mammalian Cells Exposed to Sunlight-simulating Near Ultraviolet Light in the Presence of the Carcinogen 7,12-Dimethylbenz(a)anthracene. (Eng) Utsumi, H. (Radiation Biology Center, Kyoto Univ., Kyoto 606, Japan); Elkind, M. M. *Photochem Photobiol* 30(2): 271-278; 1979.

The coal-derived carcinogen 7,12-dimethylbenz(a)anthracene (DMBA) was added in varying concentrations to cultures of V79 Chinese hamster, C3H mouse 10T1/2, and human HeLa cells. Photolethality induced by the sunlight-simulating emission from Westinghouse Sun Lamps [approx 290-400 nanomoles (nm)] was enhanced by DMBA only in the presence of O₂. Treatment of cells with DMBA after irradiation was without lethal effect; the endoperoxide of DMBA was ineffective both before as well as after irradiation, and DMBA incubation before far-UV exposure (254 nm) had a protective effect. Cells rendered photosensitive by incubation with DMBA rapidly lost their sensitivity (in <10 min at 37 C) when incubated in a DMBA-free soln containing serum, but maintained their sensitivity at least for several hours when a serum-free soln was used. Although DMBA enhanced light-induced killing of cells in all phases of the cycle, cells undergoing DNA synthesis were preferentially sensitized. The data indicate that photodynamic lethality was due to one or both of the following: (1) the reaction with DNA of DMBA radicals followed by oxidation, or DMBA-produced singlet oxygen; or (2) the peroxidation of lysosomal membranes followed by the release of hydrolases, including DNases. The results with DMBA + near-UV as a model representing the combined effects of sunlight and fossil-fuel derived polycyclic aromatic hydrocarbons are discussed in terms of altered cell properties (eg, neoplastic transformation) in sublethally affected cells. - 79-6872 Photosensitized Reactions and Carcinogenesis. (Eng) Fry, R. J. (Oak Ridge Natl. Lab., P.O. Box Y, Oak Ridge, TN 37830); Ley, R. D.; Grube, D. D. *Natl Cancer Inst Monogr* (50): 39-43; 1978.

The relationship between DNA cross-links induced by 8-methoxypsoralen (8-MOP) plus UV radiation and tumor induction was investigated in two strains of hairless mice, SKH:hairless-1 and HRS/J/An1. The mice were exposed to three light sources with emissions in the range 300-400, 320-400, and predominantly 365 nanometers (nm). 8-MOP was administered topically at doses of 250 µg 5x/wk for 24 wk, 3x/wk for 6 or 12 wk or 5x/wk for 7 wk followed by 10 µg 12-O-tetradecanoylphorbol-13-acetate (TPA) 3x/wk for 26 wk. In each case, UV radiation was administered 45-60 min after 8-MOP. In the SKH:hairless-1 mice, combined 24-wk treatment with 8-MOP and 320-400 nm UV resulted in a cumulative skin tumor incidence of approx 80%. The same irradiation without 8-MOP produced no epidermal carcinomas. The 300-400 nm range was the most tumorigenic spectrum range in the SKH:hairless-1 mice, but it produced no tumors in the HRS/J/An1 mice. The tumor incidence in mice receiving the combined treatment 3x/wk for 12 wk was markedly lower than in mice treated 5x/wk for 24 wk. When TPA was added after 12 wk of 3 exposures/wk to 8-MOP and 320-400 nm, the cumulative

tumor incidence was similar to that found with 24 wk of combined treatment without TPA promotion. The tumor response in the two strains was similar when TPA treatment followed the 8-MOP-UV exposures. Carcinoma induction by 8-MOP and 365-nm radiation suggested that psoralen photoadducts influenced tumor development. However, the strain differences in tumor incidence implied an apparent lack of relationship between psoralen DNA cross-links and tumorigenesis. It is stressed, however, that the differences in tumor incidence were due mainly to differences in expression rather than in initiation of tumors. (15 refs)

- 79-6873 Deoxyribonucleic Acid Repair Synthesis in Permeable Human Fibroblasts Exposed to Ultraviolet Radiation and N-Acetoxy-2-(acetylaminofluorene). (Eng) Roberts, J. D. (Dept. Pathology, Washington Univ. Sch. Medicine, St. Louis, MO 63110); Lieberman, M. W. *Biochemistry* 18(21): 4499-4505; 1979.

DNA repair synthesis was studied in permeable confluent normal and repair-deficient human fibroblasts using [^3H] deoxycytidine triphosphate (dCTP), bromodeoxyuridine triphosphate, deoxyATP, and deoxyguanosine triphosphate as substrates. Repair synthesis occurred as judged by the following criteria: (1) labeled nucleotides were incorporated into parental DNA ($p = 1.73 \text{ g/cm}^3$ in alkaline CsCl); (2) incorporation into parental DNA was negligible in the absence of damage and increased 10- to 20-fold in normal cells following exposure to ultraviolet radiation (UV) or the direct-acting chemical carcinogen N-acetoxy-2-(acetylaminofluorene); and (3) damage-dependent DNA synthesis was absent in preparations made from excision repair-deficient human diploid fibroblasts (xeroderma pigmentosum cells, complementation group A). The reaction was linear for 10 min and continued for at least 1 hr. Repair synthesis was stimulated at least fivefold by the addition of 5 mM ATP. It was strongly Mg^{2+} dependent, inhibited by NaCl, and only partially dependent upon the addition of exogenous deoxynucleotide triphosphates. The pH optimum in tris-HCl buffer was 7.6. Following UV damage, labeled deoxycytidine and deoxycytidine monophosphate were incorporated into parental DNA but at reduced levels (38 and 88%, respectively) compared to dCTP. The addition of $\beta\text{-NAD}^+$ (the naturally occurring isomer) or $\alpha\text{-NAD}^+$ (a competitive inhibitor) had little effect on repair synthesis in this system. By saturating the system with deoxynucleotide triphosphates and using published estimates of patch size, it was calculated that in this system a normal cell can put in a minimum of 100-900 repair patches/min. - 79-6874 Photoreactivation: Evaluation of Pyrimidine Dimers in Ultraviolet Radiation-induced Cell Transformation. (Eng) Sutherland, B. M. (Dept. Biology, Brookhaven Natl. Lab., Upton, Long Island, NY 11973). *Natl Cancer Inst Monogr* (50): 129-132; 1978.

Conditions that must be met before photoreactivation can be used as an analytical test for determining the role of pyrimidine dimers in UV damage to mammalian cells include the following: the photoreactivating enzyme (PRE) must be present in all cells, act on pyrimidine dimers in DNA, act specifically on dimers, have access to cellular DNA and thus be able to monomerize dimers in intact cells, and be able to mediate restoration of biologic function. Evidence for each of these points is examined, with particular emphasis on areas in which further experimentation is critically necessary. Human fibroblasts containing PRE, which acts on

dimers and converts them to monomers, were exposed to UV radiation from a low pressure mercury lamp, allowed to grow, and tested for their ability to grow in soft agar. Increasing exposure to UV increased the number of colonies observed on the agar plate. Exposure to photoreactivating light yielded a substantial decrease in the number of colonies per plate. These preliminary results suggest that lesions leading to cell transformation are subject to photoreactivation and that pyrimidine dimers may be important in solar carcinogenesis. (28 refs)

- 79-6875 Clinical, Genetic and DNA Repair Studies on a Consecutive Series of Patients with Xeroderma Pigmentosum. (Eng) Pawsey, S. A. (Pediatric Res. Unit, Guy's Hosp. Medical Sch., London, England); Magnus, I. A.; Ramsay, C. A.; Benson, P. F.; Giannelli, F. *Q J Med* 48(190): 179-210; 1979.

Clinical, genetic, and biochemical findings are reported for 13 families with xeroderma pigmentosum (XP); the cases included 14 patients and 2 fetuses. Twelve of the 14 patients showed a decrease in unscheduled DNA synthesis following UV irradiation, which was consistent with a deficit in excision repair; two of these patients were brother and sister. The other two patients were defective in post-replication repair. The unscheduled DNA synthesis in skin fibroblast cultures from 7/13 parents of the XP patients did not differ significantly from that of controls, but significantly lower values were found in the other six. Somatic cell fusion was used to determine to which of seven different complementation groups the patients could be assigned. Three families belonged to complementation group A, four to group C, and six to group D. The unscheduled DNA synthesis of group A cells increased with UV dose (10-150 J/m^2) but after 105 min only very moderately with time. Group C cells showed only modest dose effects and increased synthesis with time up to 45 min. Group D cells also showed only a mild dose-response, but their increase in unscheduled DNA synthesis lasted for up to 6 hr. These differences indicate that mutations of different genes play a role in XP. XP patients are highly prone to skin cancer, which indicates that a defect in dimer excision repair or bypass of photolesions during DNA replication may predispose to actinic cancers. Chromosome rearrangements, mitotic errors, polyploidization, and perhaps even the transfer of chromosome segments may all contribute to the evolution of malignant cells. There is also the possibility of an immunological change in XP that results in a tolerance toward actinic cancers by favoring the release of tumor-associated antigens. (141 refs)

- 79-6876 Inhibition of Skin Carcinogenesis In Vivo by Caffeine and Other Agents. (Eng) Zajdela, F. (Institut National de la Sante et de la Recherche Medicale, Institut du Radium, Batiment 110, 91405 Orsay, France); Latarjet, R. *Natl Cancer Inst Monogr* (50): 133-140; 1978.

The inhibition of UV-induced skin cancer by caffeine and other postreplication-repair or excision-repair inhibitors was studied in Swiss (Carshalton) mice. The induction of skin cancer by repeated irradiation with UV-light was strikingly reduced by the local application of caffeine prior to each exposure. Theophylline displayed the same activity. These two substances have been selected as probable inhibitors of error-prone, postreplicative DNA repair. Conversely, redutone and chloroquine, which are considered as inhibitors of the error-free, prereplicative excision repair, did not modify the incidence of the tumors. Special em-

phases has been given to the histologic behavior of radiolabeled caffeine in the normal and UV-irradiated epidermis of the mouse in vivo and to the ability of mouse epidermal cells in vitro to repair DNA after UV irradiation. (32 refs)

- 79-6877 DNA Excision-Repair Processes in Human Cells Can Eliminate the Cytotoxic and Mutagenic Consequences of Ultraviolet Irradiation. (Eng) Maher, V. M. (Carcinogenesis Lab., Michigan State Univ., Fee Hall, East Lansing, MI 48824); Dorney, D. J.; Mendrala, A. L.; Konze-Thomas, B.; McCormick, J. J. *Mutat Res* 62(2): 311-323; 1979.

DNA excision-repair processes in diploid human fibroblasts were able to eliminate potentially cytotoxic and mutagenic lesions induced by UV radiation (254 nanomoles), as shown in either of two ways. Cells with normal rates of excision were compared with cells with an intermediate excision rate (XP2BE) and cells with an excision rate $\leq 1\%$ of the normal rate (XP12BE) for sensitivity to UV-induced killing and mutation. The normal cells proved resistant to UV doses which in XP cells reduced survival to 14% and 0.7%, respectively, and increased the frequency of mutations to 8-azaguanine resistance 5- to 10-fold over background. Cells in confluence were irradiated with cytotoxic and mutagenic doses of UV and allowed to carry out excision repair. After various lengths of time they were replated at lower densities to allow for expression of mutations to 6-thioguanine resistance and/or at cloning densities to assay survival. Normal cells and XP2BE cells exhibited a gradual increase in survival from an initial level of 15-20% to 100% if held approx 20 hr in confluence. In contrast, XP12BE cells showed no increase from an initial survival of 20% even when held for 7 days. Normal cells irradiated in confluence but prevented from replicating for 7 days exhibited background mutation frequencies, whereas the mutation frequency in XP12BE cells did not change with the time in confluence. (22 refs)

- 79-6878 Further Characterization of Immunological Unresponsiveness Induced in Mice by Ultraviolet Radiation. Growth and Induction of Nonultraviolet-induced Tumors in Ultraviolet-irradiated Mice. (Eng) Kripke, M. L. (Cancer Biology Program, NCI, Frederick Cancer Res. Center, Frederick, MD 21701); Thorn, R. M.; Lill, P. H.; Civin, C. I.; Pazmino, N. H.; Fisher, M. S. *Transplantation* 28(3): 212-217; 1979.

Specific-pathogen-free mice of several inbred strains were irradiated with UV light, their susceptibility to primary and transplanted tumors etiologically unrelated to UV radiation was compared with that of unirradiated mice. Although the UV-irradiated mice were unable to reject transplants of highly antigenic syngeneic tumors induced by UV light, the growth of syngeneic, non-UV-induced tumors generally was not accelerated in these animals. Furthermore, the UV-irradiated mice were no more susceptible to the induction of primary leukemias, mammary tumors, or sarcomas than were unirradiated animals. Tests of immune responses to weak transplantation antigens showed that UV-irradiated mice rejected H-Y-incompatible skin grafts as vigorously as did normal animals and that the primary in vitro cytotoxic responses of spleen cells from UV-irradiated mice to trinitrophenyl-modified syngeneic cells and to Hh antigens were unaffected. It is concluded that the susceptibility of UV-irradiated mice to challenge with UV-induced tumors represents a selective unresponsiveness, and that it is not attributable to a generalized deficiency in the immune response to tumor-specific antigens or to weak transplantation antigens. (26 refs)

- 79-6879 A Systemic Effect of Ultraviolet Irradiation and Its Relationship to Tumor Immunity. (Eng) Fisher, M. S. (Cancer Biology Program, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701). *Natl Cancer Inst Monogr* (50): 185-193; 1978.

Chronic irradiation of mice with UV light produces a systemic alteration that is immunologic in nature and may be due to the presence of specific suppressor lymphoid cells. The immunologic aspect of this systemic alteration was demonstrated by cell transfer experiments. Lymphoid cells from UV-treated donors were unable to confer tumor resistance to lethally x-irradiated and neonatal liver reconstituted recipients, whereas recipients given lymphoid cells from normal donors were resistant to a challenge with a syngeneic UV-induced tumor. Therefore, lymphoid cells from normal donors could mediate tumor rejection, but lymphoid cells from UV-irradiated donors could not. Furthermore, lymphoid cells from UV-treated donors suppressed the ability of lymphoid cells from normal donors to mediate syngeneic tumor rejection when mixed 1:1 before transfer to lethally x-irradiated recipients. This suppression was specific since all recipients resisted an allogeneic UV-induced tumor challenge. Serum transfer experiments failed to demonstrate any inactivating or suppressive substances in the serum of UV-treated mice. These results suggest that UV-treated mice failed to reject UV-induced tumors because irradiation induced specific suppressor lymphoid cells that prevented the development of an immune response against tumor antigens. - 79-6880 Ultraviolet Wavelength Regions Implicated in Toxic and Mutagenic Effects of Broad Spectrum Radiation from Fluorescent Lamps on L5178Y Mouse Lymphoma Cells. (Eng) Jacobson, E. (Div. Biological Effects, Bureau Radiological Health, FDA, HEW, 5600 Fishers Lane, Rockville, MD 20857); Krell, K. *Mutat Res* 62(3): 533-538; 1979.

Emitted light from four commercially available fluorescent lamps was tested for mutagenic and toxic effects on mouse L5178Y lymphoma cells in vitro in order to identify the region of the spectrum responsible for such effects of broad spectrum radiation from fluorescent lamps. Irradiance spectra were determined for wavelengths between 250 and 800 nanometers (nm) with special attention to the range 280-390 nm. Surviving fraction (toxicity) and mutations per 10^5 surviving cells (mutagenicity) were reported after exposure of cultures (at 8 cm distance for a period of time allowing for uniform dose) to filtered or unfiltered light from each lamp. No single wavelength was found to be particularly responsible for mutagenicity or toxicity. It is suggested that relative intensities of several wavelengths in the UV and near UV region may be responsible and that different portions of the spectrum may be involved in mutagenesis and toxicity. - 79-6881 Workshop on Production and Measurement of Ultraviolet Light: Light Sources for Solar Simulation in Photocarcinogenesis Studies. (Eng) Forbes, P. D. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Natl Cancer Inst Monogr* (50): 91-95; 1978.

Light sources for solar simulation in photocarcinogenesis studies include the xenon lamp fitted with a borosilicate filter, an infrared (IR)-absorbing glass filter, or a Schott glass filter. The advantages and disadvantages of each filter system used are discussed. Current

experiments are using the Schott WG 320 filter to give the same Robertson-Berger (sunburn meter) reading as IR-absorbing filters while solving problems concerning light quantity and light quality. Since the WG 320 filtered system is known to produce tumors in mice, it will be useful in examining possible interactive effects of the solar spectrum. (8 refs)

- 79-6882 Action Spectrum for Ultraviolet Carcinogenesis. (Eng) Freeman, R. G. (Dept. Pathology, Univ. Texas Health Sciences Center, Midwestern Medical Sch., Dallas, TX 75235). *Natl Cancer Inst Monogr* (50): 27-29; 1978.

High-intensity monochromatic UV wavelengths of 290-320 nanometers (nm) were compared for their efficacy in inducing tumors in mice, to test the hypothesis that carcinogenic effectiveness was proportional to erythral activity. Groups of albino mice were exposed to the UV light 3x/wk on one ear with the opposite ear serving as control. The experiment was halted when 50% of the surviving animals developed tumors. UV irradiation at 300 nm produced skin tumors, but radiation at 310 nm did not. In the 300-nm group, the first tumor appeared after 323 days, and 50% of the animals developed tumors by 458 days. All of the tumors were squamous cell carcinomas. A second series of experiments was performed in which the mice were exposed to UV at 290, 310, and 320 nm in dosages proportional to the threshold dose for erythema production in untanned human skin. At 310 nm, no tumors were observed in mice exposed to low levels [60 millijoules (mJ)/cm²/wk]; at high levels (750 mJ/cm²) tumors were induced, and their first appearance and time at which 50% of the survivors developed tumors paralleled the responses of mice receiving 60 mJ/cm²/wk at 300 nm. The 8 tumors in the 16 survivors included 5 squamous cell carcinomas, 2 fibrosarcomas, and 1 angiosarcoma. Tumors were also observed after 417 and 464 days, in 2/5 mice receiving UV energy at 320 nm. No tumors of visible damage occurred in mice exposed to UV at 290 nm. These results demonstrate that the carcinogenicity of UV is proportional to its erythral potency. (13 refs)

- 79-6883 Ultraviolet Light in the Oncogenic Transformation of Cultured C3H/10T1/2 Mouse Embryo Cells. (Eng) Mondal, S. (Univ. Southern California Cancer Center, Los Angeles, CA 90031); Heidelberg, C. *Natl Cancer Inst Monogr* (50): 71-73; 1978.

A mouse embryo fibroblast line, C3H/10T1/2, that can be transformed by chemical carcinogens, x-irradiation, UV radiation, and oncornavirus was developed. When these cells were irradiated with 10, 25, 50, 100, 150, or 200 ergs/mm² of UV light, neither transformation nor cytotoxicity was observed at the two lower doses. When the irradiated cells were cultured in medium containing tetradecanoylphorbol acetate (TPA: 0.1 µg/ml) starting from 0-120 hr after irradiation, a high frequency of transformation was always produced. When the cells were initiated with subeffective concentrations of 3-methylcholanthrene (0.1 µg/ml) followed by UV radiation at different intervals, no transformation occurred; however, these initiated cells were transformed after TPA treatment. No transformation occurred when the cells were treated with multiple exposures to UV light, nor when the cells were treated with TPA followed by UV irradiation at different intervals. UV in this system acts as a pure initiator in the two-stage process of oncogenic transformation. (15 refs)

- 79-6884 Experimental Ultraviolet Photocarcinogenesis: Wavelength Interactions and Time-Dose Relationships. (Eng) Forbes, P. D. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Health Sciences Center, Philadelphia, PA 19140); Davies, R. E.; Urbach, F. *Natl Cancer Inst Monogr* (50): 31-38; 1978.

Variables that affect quantitative models of UV photocarcinogenesis were studied in SKH hairless mice. Skin tumors were induced in these mice by exposure to fluorescent FS sun lamps or to a long-arc xenon solar simulator. Tumors developed about equally well with varying amounts of UV-A radiation ($\lambda > 320$ nm) led to substantial increases in carcinogenic effectiveness. A tumor-initiating dose of UV-B (280-320 nm; 4-10 wk of daily FS lamp exposures) was rendered less effective by subsequent exposures of the mice to UV-A (6 hr/day, F-40 T12BL lamps). Most tumors induced by a short course (10 wk) of FS lamp exposure grew slowly or regressed, whereas mice exposed for a longer period (30 wk) developed more tumors, and many of those that appeared early grew aggressively. The effects of daily dose fractionation were less clear. The above variables, as well as others, are being tested in a program designed to yield useful information on the effects of changing spectrum, dose, and dose-delivery rates on sunlight-induced cancer. (17 refs)

- 79-6885 Life History and Histopathology of Ultraviolet Light-Induced Skin Tumors. (Eng) Stenback, F. (Dept. Pathology, Univ. Kuopio, Harjulantie 1, 70100 Kuopio 10, Finland). *Natl Cancer Inst Monogr* (50): 57-70; 1978.

Histologic, histochemical, and ultrastructural methods were used to study the immediate and long-term effects of UV irradiation of different wavelengths on the skin of NMR rats, outbred female Swiss mice, and Syrian golden hamsters. High-intensity UV light of medium wavelengths produced hyperplasia and papillomas, as well as a dysplastic, intermediary solar keratosis-like stage, with distinct cellular atypia leading to several types of squamous cell carcinomas. High doses of UV irradiation of short duration caused scars, which developed into fibromas and fibrosarcomas composed of "light" and "dark" cells. Carcinomas with neoplastic squamous and fibrous components were uncommon; however, collision tumors with two components were occasionally seen. Angiomas and angiosarcomas with a proliferating endothelial structure were observed, but adnexal tumors, with follicular or sebaceous differentiation, and basal cell carcinomas were infrequent. Pigment-cell tumors were rarely found. The number of tumors and tumor-bearing animals at different stages of the experiment were also studied. Tumors were compared with lesions induced by chemical carcinogens in different systems. UV carcinogenesis was characterized by many tumor-bearing animals, but with a low total tumor count and a high mortality, thereby decreasing the number of animals-at-risk. The tumor types, their progression from one type to another, and the distribution of certain biologic characteristics were also analyzed. It is concluded that UV irradiation is an effective tumor inducer in animal skin and that the type of tumor, its behavior, and its location depend on the experimental conditions. (29 refs)

- 79-6886 Influence of Heat, Wind, and Humidity on Ultraviolet Radiation Injury. (Eng) Owens, D. W. (Kelsey-Seybold Clinic, 6624 Fannin St., Houston, TX 77030); Knox, J. M. *Natl Cancer Inst Monogr* (50): 161-167; 1978.

The influence of heat, wind, and humidity on the acute and chronic skin damage caused by UV radiation (UVR) to mice housed in environmental chambers and irradiated under controlled conditions was investigated. Hairless HRS/J mice irradiated at room temperature (71 F) developed distinct erythema and small scaling areas by the third day after irradiation. Those irradiated after their skin had been heated to 98 F developed more intense erythema, crusting and necrosis. Animals irradiated after cooling of their skin to 58 F developed only mild erythema and small scaling areas. In experiments concerning environmental temperature, Swiss albino mice demonstrated an increased number and rate of tumor development when kept at 90 F than those kept at room temperature. Swiss albino mice exposed to UVR and wind had greater skin damage than those exposed to radiation alone. Wind also accelerated tumorigenesis in mice that received chronic UVR. Hairless HRS/J mice exposed to high humidity (80%) had more severe skin damage after UVR than those kept at low humidity (5%). Mice kept at high humidity and irradiated developed skin tumors earlier (day 76) than those kept at low humidity (20%; day 154). Since heat, wind, and humidity enhance acute as well as chronic UV injury and carcinogenesis, these influences should be considered in any biologic experiment on UV injury. (11 refs)

- 79-6887 Immunologic Aspects of Tumor Induction by Ultraviolet Radiation. (Eng) Kripke, M. L. (Cancer Biology Program, Frederick Cancer Res. Center, P.O. Box B, Frederick, MD 21701); Fisher, M. S. *Natl Cancer Inst Monogr* (50): 179-183; 1978.

The general immune competence of UV-treated animals was tested in various in vivo and in vitro assays. These responses included tumor allograft rejection, skin graft rejection, antibody production against sheep RBC, graft-vs-host reactivity, delayed hypersensitivity to dinitrochlorobenzene, inflammatory response, lymphocyte blastogenesis, and macrophage functions. Chronic treatment of mice with UV radiation induced skin cancer and produced a systemic change that interfered with host resistance against these tumors. After a short course of UV radiation, the UV-irradiated mice lost their ability to reject transplanted UV-induced tumors, even though such transplants were rejected by unirradiated animals. The growth of the transplanted tumors in UV-treated mice was attributed to a systemic alteration in animals induced by UV irradiation of the skin. UV-irradiation does not appear to decrease host resistance against all syngeneic tumors per se, or even against all syngeneic fibrosarcomas; three dermal tumors grew more rapidly in UV-treated mice. Whether this acceleration is immunologically mediated and stems from antigenic similarities among these and UV-induced tumors, or whether this is due to the physiologic effects of UV treatment on the host is unknown. (21 refs)

- 79-6888 Effect of Dietary Cholesterol on Ultraviolet Light Carcinogenesis. (Eng) Black, H. S. (Photobiology Lab., Building 203, Rm 134, Veterans Admin. Hosp., Houston, TX 77211); Henderson, S. V.; Kleinhans, C. M.; Phelps, A. W.; Thornby, J. I. *Cancer Res* 39(12): 5022-5027; 1979.

Several levels of dietary cholesterol, as well as antioxidant additives, were tested for their effect on ultraviolet light (UV) carcinogenesis. Hairless mice were divided into 12 groups of 50 animals each. The animals received a restricted, semipurified, isocaloric diet containing 0, 0.01, and 2% cholesterol with or without addition of a 2% (w/w) antioxidant mixture. A regimen of

escalating UV irradiation was used until a cumulative dose of 145 joules/cm² had been delivered. Animals were evaluated weekly for actinic lesions and biweekly for body wt, hematocrits, and serum cholesterol levels. A cumulative distribution frequency, based upon the asymptotic theory of extreme values, was used to determine tumor occurrence with time of study. Tumor development time for 50% of the animals for each dietary cholesterol level used was significantly different, with a longer development period occurring with increasing cholesterol level. Dietary antioxidants significantly suppressed UV-induced tumor formation, although this effect was not as pronounced as that seen in previous studies with commercial diets. The data indicate that dietary cholesterol does not enhance UV carcinogenesis but rather has a slight, but significant, moderating effect. This effect could result from direct participation of dietary cholesterol in the carcinogenic process or, alternatively, could occur as the result of sterol-altered epidermal parameters which effectively diminish the UV dose reaching target sites. (37 refs)

- 79-6889 Enhancement of Experimental Photocarcinogenesis by Topical Retinoic Acid. (Eng) Forbes, P. D. (Center Photobiology, Skin and Cancer Hosp., Temple Univ. Sch. Medicine, Philadelphia, PA 19140); Urbach, F.; Davies, R. E. *Cancer Lett* 7(2/3): 85-90; 1979.

Groups of hairless albino mutant mice (30 males, 30 females) received daily topical applications of all trans-retinoic acid (RA) starting at 7 wk of age for 30 wk (group A, methanol only; group B, 0.001% RA; and group C, 0.01% RA). Another group was treated with 0.1% croton oil daily (group D). Starting on the 1st day of croton oil treatment and the 15th of RA, each application was preceded by a 2-hr exposure to a xenon arc filtered through 2 mm of Schott WG 320 glass (approx equivalent in human erythema effectiveness to 5 min of mid-summer noon solar exposure in northern mid-latitudes). Tumors >1 mm in diameter first appeared in group A at 38 wk, group B at 21 wk, group C at 20 wk, and group D at 26 wk. At wk 55, animals in group A had 0.65 tumors/survivor; in group B, 6.3 tumors/survivor; in group C, 9.22 tumors/survivor; and in group D, 0.89 tumors/survivor. Skin tumors were histologically diagnosed as carcinoma in situ or squamous cell carcinoma. No metastases were detected. Slight scaling and flaking of the skin, but no gross evidence of erythema or irritation, was noted in RA-treated groups. These results indicate that topical application of RA to the skin of albino hairless mice significantly enhances the carcinogenic effectiveness of simulated sunlight. (22 refs)

- 79-6890 Pyrimidine Dimer Excision in Human Cells and Skin Cancer. (Eng) Regan, J. D. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN 37830); Carrier, W. L.; Smith, D. P.; Waters, R.; Lee, W. H. *Natl Cancer Inst Monogr* (50): 141-143; 1978.

Three methods were compared for estimating the induction and removal of UV-induced pyrimidine dimers from the DNA of human fibroblasts (normal, xeroderma pigmentosum, and Fanconi's anemia). The approaches included pyrimidine-dimer chromatography that directly measured the percent of labeled thymidine existing as dimers in acid-insoluble DNA, a UV endonuclease incubation that induced a single-strand break next to and in the same DNA strand as the pyrimidine dimer, and bromodeoxyuridine (BrdUrd) photolysis, which estimated the number of pyrimidine dimers removed and repaired by excision

resynthesis and rejoining and the av size of the repair region for each dimer removed. All three methods indicated that after UV doses of 5-20 Joules/m², 50% of the dimers are removed by 24 hr. Almost complete excision is observed when the cells are incubated for periods of ≥ 72 hr after a dose of 5 Joules/m². The dimers are removed slowly by excision repair, and repair must operate actively for 3-4 days to remove all the dimers. (17 refs)

- 79-6891 Transformation Frequency of Syrian Golden Hamster Cells and Its Modulation by Ultraviolet Irradiation. (Eng) DiPaolo, J. A. (Biology Branch, Carcinogenesis Program, Div. Cancer Cause Prevention, NCI, Bethesda, MD 20205); Donovan, P. J. *Natl Cancer Inst Monogr* (50): 75-82; 1978.

Experiments in which UV radiation (253.7 nm) exposure of Syrian golden hamster cells seeded for colony formation caused an induction of transformation without any other insult are reported. Analysis of the quantitative data demonstrated a lack of a threshold response and a transformation frequency proportional to UV dose. No transformation occurred in unirradiated colonies. When cells seeded for colony formation were exposed to UV and subsequently treated with N-acetoxy-2-acetyl aminofluorene (AcAAF), a carcinogen known to induce UV-like damage, neither an additive nor a synergistic effect occurred. Caffeine at nontoxic concentrations potentiated lethality caused by AcAAF and also increased the number of colonies transformed by AcAAF when added post-AcAAF. The addition of a constant amount of caffeine (50 μ g/ml) for 48 hr at different intervals after carcinogen treatment resulted in max enhancement (10- to 17-fold) when added 4 hr post-AcAAF. UV-associated transformation was enhanced by pretreating the cells with a nontransforming dose of x-irradiation 48 hr before UV. The increase in transformation frequency was 6- to 12-fold per colony and 3- to 6-fold per dish. (21 refs)

- 79-6892 Description and Application of a Personal Ultraviolet Dosimeter: A Review of Preliminary Studies. (Eng) Challoner, A. V. (Dept. Physics, St. John's Hosp. Diseases of the Skin, Homerton Grove, London, England); Corbett, M. F.; Davis, A.; Diffey, B. L.; Leach, J. F.; Magnus, I. A. *Natl Cancer Inst Monogr* (50): 97-100; 1978.

Preliminary investigations of a dosimeter that can be used to measure individual exposures to UV radiation are described. The method is based on the use of polysulfone film, which, on exposure to UV, shows a change in absorbance that can be determined spectrophotometrically. Medical applications of the dosimeter are discussed. It is concluded that a personal film badge dosimeter gives information that complements that from a static electronic monitor and that such dosimeters would be useful for epidemiologic studies of UV-induced skin cancer. (12 refs)

- 79-6893 Effect of Antipain on Radiation Induction of Endogenous Type-C Virus from Mouse Cells In Vitro. (Eng) Niwa, O. (Dept. Experimental Radiology, Kyoto Univ., Sakyo-ku, Kyoto 606, Japan); Sugahara, T. *Intervirology* 12(2): 120-123; 1979.

The effect of antipain (AP) on the radiation-induced expression of endogenous type-C virus from K-Balb mouse cells was studied in vitro. Incubation with antipain (≤ 5 mM) for 24 hr did not modify the plating efficiency, or x-ray sensitivity of the K-Balb cells or the

UV sensitivity of mouse L cells. However, UV- or x-ray-induced virus expression was markedly reduced by postirradiation treatment with antipain concentrations as low as 0.1 mM; the max level of inhibition was attained at concentrations higher than 5 mM. Spontaneous induction was also suppressed by antipain, but bromodeoxyuridine-induced virus expression was unaffected by the drug at concentrations up to 10 mM. Less than 4 hr postirradiation, treatment with antipain was sufficient to cause max inhibition of radiation-induced virus expression. The data suggest that a proteolytic step is involved in the radiation induction of endogenous type-C virus, while a different mechanism such as altered binding affinity of chromatin protein to DNA might be responsible for virus expression induced by halogenated pyrimidines. - 79-6894 Role of Photosensitization and Oxygen in Chromosome Stability and "Spontaneous" Malignant Transformation in Culture. (Eng) Sanford, K. K. (Lab. Cellular and Molecular Biology, Div. Cancer Cause and Prevention, NCI, NIH, Public Health Service, Bethesda, MD 20205); Parshad, R.; Jones, G.; Handleman, S.; Garrison, C.; Price, F. J. *Natl Cancer Inst* 63(5): 1245-1255; 1979.

The enhancement of both chromosome instability and malignant transformation of mouse cells in culture by visible light and oxygen was investigated. Nine cell lines were initiated from eight pools of 10- to 13-day C3H embryos. Each cell line was divided into sublines, which were either maintained shielded from light or were exposed for 3 or 24 hr to fluorescent light (approx 150 foot-candles) 2 or 3x/wk. Cultures of the sublines were also maintained with either a gaseous phase of 0-1% oxygen or atmospheric (18%) oxygen. Each line was monitored for cytologic manifestations of malignant neoplastic transformation, and eight lines were monitored for chromosome alterations. Seven lines were assayed for tumorigenicity by intraocular implantation into syngeneic hosts. Repeated light exposure and/or a high level of oxygen increased the frequency of minute chromosomes, which result from chromatid breaks, and also increased the rate of shift from the diploid to the heteroploid state. Four cell lines showed no cytologic changes indicative of neoplastic change during the test period. Two of these were assayed in vivo and failed to grow as tumors. In the remaining six lines, neoplastic colonies appeared earlier or more abundantly in light-exposed cultures and/or those gassed with high oxygen. In three of these lines, tumors developed only from light-exposed cultures; in the other two, tumor latency periods were significantly shorter in cultures exposed to light or gassed with atmospheric oxygen. - 79-6895 A Negative Test for Mutagenic Action of Microwave Radiation in *Drosophila melanogaster*. (Eng) Hamnerius, Y. (Res. Lab. Electronics, Chalmers Univ. Technology, Goteborg, Sweden); Olofsson, H.; Rasmuson, A.; Rasmuson, B. *Mutat Res* 68(3): 217-223; 1979.

The mutagenicity of microwave radiation [2,450 MHz continuous waves (CW)] was tested in *Drosophila melanogaster*. Embryos in water were exposed to the electromagnetic field with a mean specific absorption rate of 100 W/kg. A sensitive somatic test system was used, in which mutagenicity was measured as the frequency of somatic mutations for eye pigmentation. In this test system, microwaves showed no mutagenic activity. (19 refs)

- 79-6896 **Experimental Squamous Cell Lung Tumors in Sprague-Dawley and Murine Pneumonitis-free Rats.** (Eng) Gracey, D. R. (Mayo Clinic, Rochester, MN 55901); Fish, J. E.; Divertie, M. B. *Cancer* 44(2): 598-603; 1979.

Radioactive pegs (ruthenium-105/rhodium-106 microspheres embedded in a polyurethane peg) were placed in the lungs of 32 pathogen-free rats and 28 Sprague-Dawley rats, and the animals were killed 12-13 wk after implantation. In 11/32 pathogen-free rats with radioactive pegs, lung tumors, histologically and ultrastructurally resembling well-differentiated squamous cell bronchogenic carcinomas, developed after an av of 139 days. None of the pathogen-free rats with nonradioactive pegs developed tumors. Fifteen Sprague-Dawley rats with radioactive pegs showed well-differentiated squamous cell carcinoma after an av of 147 days. No evidence of metastases to extrapulmonary tissue was observed. The difference between the time of exposure and development of neoplasms between the specific pathogen-free and the Sprague-Dawley rats that received radioactive pegs was not significant. Various degrees of murine pneumonitis were present in all Sprague-Dawley rats, but this was not seen in the specific pathogen-free rats. These results indicate that murine pneumonitis is not a prerequisite for the development of neoplasia produced by point-source irradiation. The histologic and cytologic features of this experimental tumor are consistent with the appearance of a highly differentiated invasive bronchogenic squamous cell tumor in man, making this a valuable model for the study of this disease. - 79-6897 **Intrinsic and Extrinsic Variables Affecting Sensitivity to Radiation Carcinogenesis.** (Eng) Yuhas, J. M. (Cancer Res. and Treatment Center, Univ. New Mexico, Albuquerque, NM 87131). *Int J Radiat Oncol Biol Phys* 5(7): 1117-1122; 1979.

The linear *plus* quadratic model, which is particularly useful in radiation carcinogenesis, is examined in terms of the types of injury that can contribute to it and in terms of its reliability in predicting the effects of dose protraction. Through the analysis of simple experimental systems, it is demonstrated that $aD + bD^2$ kinetics can result from injury to the cells that eventually develop into cancer (target cells) or from injury to cells that affect target cell survival. These kinetics can fail to predict the consequences of dose protraction, which is largely due to the fact that transformation increases with dose whereas survival decreases. The role of these models in helping to develop an understanding of mechanisms should therefore be restricted to the formulation of basic hypotheses, which are subject to direct testing in the laboratory. (21 refs)

- 79-6898 **In Vitro Neoplastic Transformation of Plant Callus Tissue by γ -Radiation.** (Eng) Pandey, K. N. (Thomas Hunt Morgan Sch. Biological Sciences, Univ. Kentucky, Lexington, KY 40506); Sabharwal, P. S. *Mutat Res* 62(3): 459-465; 1979.

Tumors have been induced by ^{60}Co - γ -radiation (100-3,000 rads) in callus tissue derived from a monocotyledonous flowering plant (*Haworthia mirabilis* Haw.). The transformed tissue exhibited compact texture, excessive cell proliferation and loss of capacity for organogenesis. Tumors were characterized by their ability to undergo continuous autonomous growth on minimal media in the subsequent four generations of subculture. In contrast, the nonir-

radiated control tissue grew with friable texture, required inositol or growth hormones, and showed prolific differentiation of vegetative buds. (17 refs)

- 79-6899 **Micronuclei Induced by X-Rays and Chemical Mutagens in Meiotic Pollen Mother Cells of Tradescantia. A Promising Mutagen Test System.** (Eng) Ma, T. H. (Dept. Biological Sciences, Western Illinois Univ., Macomb, IL 61455). *Mutat Res* 64(5): 307-313; 1979.

In *Tradescantia* species, pollen mother cells of each of the buds of an inflorescence are synchronized at different meiotic stages, thus facilitating the treatment of the appropriate buds containing only the mutagen-sensitive, prophase stage. Damage to chromosomes at early prophase can be determined by scoring the frequency of micronuclei (MCN) in tetrads 24-30 hr after treatment. The high efficiency and the versatility of this 'MCN-in-Tetrad' test system were demonstrated for radiation and for chemical mutagens. When inflorescences of the plant cuttings were exposed to 20 and 40 R of x-rays, an av of 22.8 and 66.6 MCN/100 tetrads were observed respectively. Liquid ethyl methanesulfonate (EMS) at 50 and 100 mM absorbed through the stem induced 13.2 and 15.2 MCN/100 tetrads respectively, while gaseous EMS (1000 ppm) induced 17.4 MCN/100 tetrads. Liquid sodium azide (NaN_3), at 0.2 mM induced 10.1 MCN/100 tetrads, while 136 ppm of gaseous hydrazoic acid (HN_3), which is the fume released from NaN_3 reacted with acid, induced 21.2 MCN/100 tetrads. The control of each of the experimental groups yielded around 5 MCN/100 tetrads. (18 refs)

- 79-6900 **Teratogenic Interaction of Hyperthermia and Vitamin A.** (Eng) Ferm, V. H. (Dept. Anatomy/Cytology, Dartmouth Medical Sch., Hanover, NH 03755); Ferm, R. R. *Biol Neonate* 36(3/4): 168-172; 1979.

The teratogenic effects of hyperthermia (39.5 C for 60 min) and vitamin A (5,000 U/100 g by stomach tube) were tested in LVG hamsters treated on day 8 of gestation. Heat alone caused a malformation rate of 7.5%, by day 13 of gestation, 8/24 litters showing at least one malformation. Vitamin A caused a malformation rate of 3.3%, 6/25 litters showing at least one fetus with an abnormality. Heat plus vitamin A caused a malformation rate of 36.4%, 22/25 litters showing one or more fetuses with malformations. All six litters treated with 20,000 U/100 g vitamin A alone had one or more abnormal fetuses, and 78.8% of the surviving fetuses from these litters were malformed. Exencephaly, encephalocele, and defects of the eye, face, lip, ribs, and tail were observed. The data suggest that maternal hyperthermia may be an important synergistic factor for a variety of potentially teratogenic influences during pregnancy. (15 refs)

- 79-6901 **Acoustic Neurinoma After Irradiation: Report of a Patient Treated for Facial Acne and Thyroid Carcinoma.** (Eng) Rhie, F. H. (E. P. Joslin Res. Lab., Harvard Medical Sch., Boston, MA); Zellmann, H. E. *Lahey Clin Found Bull* 27(4): 142-146; 1978.

The development of an acoustic neurinoma 8 yr after thyroidectomy and therapeutic irradiation for papillary carcinoma of the thyroid and metastases in a 27-yr-old woman is reported. At age 12 yr, the patient had undergone 16 courses of facial irradiation for

PHYSICAL CARCINOGENESIS

acne. Headache and facial numbness developed 4 yr after therapeutic irradiation for the thyroid carcinoma, suggesting the presence of acoustic neurinoma at this time, although positive diagnosis was not made until 4 yr later. It is suggested that the thyroid carcinoma and acoustic neurinoma were related to the patient's initial facial irradiations. (13 refs)

- 79-6902 An Intracranial Sarcoma Following Radiation of a Hypophyseal Adenoma. (Ger) Gerlach, H. (Pathologisches Institut des Bereichs Medizin, Martin-Luther-Universität, Leninalle 14, DDR-402 Halle, W. Germany); Janisch, W. *Zentralbl Neurochir* 40(2): 131-133, 135-136; 1979.

An intracranial fibrosarcoma was diagnosed at the autopsy of a 47-yr-old woman who had undergone radiation therapy (RT) for hypophyseal adenoma beginning 24 yr previously. The first RT series was 50% of the skin-erythema dose, given 14 times. Ten yr later, 2,500 rads were given to each (right and left) temporal field for symptoms of recurrence. The tumor recurrence was removed surgically 15 yr after the original diagnosis and identified as a chromophobic adenoma. Later, diabetes insipidus and severe headaches developed. The sella region was no longer discernible by x-ray. RT (1,000 rads/session) was begun, but the patient died before the planned therapy was completed. Her sella turcica region was occupied by a tennis-ball sized tumor containing collagen fibers and anaplastic spindle-type cells with atypical mitoses. The numerous mitoses may have resulted from the recent RT. Some traces of hypophyseal adenoma were found within the fibrosarcoma. No metastases were found. Twelve other cases of similar tumors developing after RT for hypophyseal adenomas were found in the literature, with an av latency of 10 yr (3-20 yr range). The finding of adenoma-cell nests in all areas of the sarcoma may indicate that the sarcoma arose in the stroma of the first tumor. (10 refs)

- 79-6903 X-Ray or γ -Ray Leukemogenesis in Mouse. (Eng) Rosen, P. (Hasbrouck Lab., Univ. Massachusetts, Amherst, MA 01003). *Med Hypotheses* 5(10): 1141-1144; 1979.

A theoretical model is presented for x-ray or γ -ray leukemogenesis in the mouse. The first step, a double strand break in the viral part of the genome, leads to constitutive production of the viral protein responsible for transformation by derepression of its operator control region. The second step involves binding of viral protein to the regulator gene of a two repressor system: binding to the gene of the first repressor leads to synthesis of the second, which will repress the expression of the leukocyte maturation gene. Results are compared with experimental results on CBA mice, and good agreement is found. (15 refs)

- 79-6904 X-ray Induced DNA Double Strand Break Production and Repair in Mammalian Cells as Measured by Neutral Filter Elution. (Eng) Bradley, M. O. (Lab. Experimental Pathology, Human Tissue Section, NCI, NIH, Bethesda, MD 20205); Kohn, K. W. *Nucleic Acids Res* 7(3): 793-804; 1979.

A neutral filter elution method for detecting DNA double strand breaks in mouse L1210 cells after x-ray is described. The assay detects the number of double strand breaks induced by as little as 1,000 rad of x-ray. The rate of DNA elution through the filters under neutral conditions increases with x-ray dose. Certain condi-

tions for deproteinization, pH, and filter type were shown to increase sensitivity. Hydrogen peroxide and bleomycin also induced apparent DNA double strand breaks, although the ratios of double to single strand breaks varied from those produced by x-ray. The introduction of double strand cuts by Hpa I restriction endonuclease in DNA lysed on filters resulted in a rapid rate of elution under neutral conditions, implying that the method can detect double strand breaks if they exist in the DNA. The eluted DNA banded with a double stranded DNA marker in cesium chloride, suggesting that the assay does detect DNA double strand breaks. L1210 cells were shown to rejoin most of the DNA double strand breaks induced by 5-10 krad of x-ray with a half-time of about 40 min. (11 refs)

- 79-6905 Basiliomas After Radiation Treatment of Hemangiomas. (Ger) Hadlich, J. (Hautklinik der Medizinischen Akademie Erfurt, Klement-Gollwald Strasse 34, DDR-508 Erfurt, E. Germany); Linse, R. *Dtsch Gesundheitswes* 34(10): 447-449; 1979.

Two cases are described in which basiliomas developed at the site of radiation treatment for a childhood hemangioma. A 16-yr-old girl presented with a tumor of irregular lumps within an area of radiation damaged skin on her back. She had been treated for hemangioma in this back area at age 2 yr. The second patient was irradiated at age 1 yr for hemangioma on her neck. At age 24 yr she noted a lesion in this area which sometimes oozed. When she came for treatment 1 yr later the lesion was ulcerated. Recent studies show the spontaneous regression rate of hemangiomas to be 80%-90%, and that radiation treatment does not significantly increase this rate. Thus radiation for childhood hemangiomas is not recommended. Freezing the area with CO₂ snow or liquid nitrogen should be tried for those that do not regress. Radiation damaged skin should be regarded as a precancerous condition. Small areas of damaged skin should be surgically removed. Patients with areas too large to be removed should be carefully followed. (28 refs)

- 79-6906 The significance of Leucocytosis in the X-irradiated Tumour-Bed. (Eng) Engel, D. (Pathology Dept., Univ. Zurich, Zurich, Switzerland). *Strahlentherapie* 155(9): 637-643; 1979.

Tumor growth and leukocytosis were studied in inbred NMRI mice subjected to x-irradiation (900 Rad) of the right loin-thigh area 1-30 days before the sc implantation of Ehrlich's mouse carcinoma into the irradiated and nonirradiated loin-thigh areas. The total tumor wt on the irradiated side (69.24 g) was approx half that of the nonirradiated control side (122.11 g). The number of leukocytes increased rapidly in the irradiated area during the first 24 hr after irradiation, then rapidly decreased to near normal by the fifth day after irradiation. Inflammation was never observed on the control side. The inhibitory effect of x-irradiation on tumor growth and the inflammatory response of the skin did not run a parallel course except during the first few days after irradiation, suggesting that hyperleukocytosis of the tumor bed is not the only cause for radiation-induced inhibition of tumor growth. (23 refs)

- 79-6907 Effect of Host Immune Capability on Radiocurability and Subsequent Transplantability of a Murine Fibrosarcoma. (Eng) Stone, H. B. (Dept. Radiology and Radia-

tion Biology, Colorado State Univ., Fort Collins, CO 80523; Peters, L. J.; Milas, L. *J Natl Cancer Inst* 63(5): 1229-1235; 1979.

The effect of host immune capability on the TCD50 (radiation dose required for local control of tumors in 50% of animals) and on the slope of the dose-response curve for tumor control in mice bearing a highly immunogenic fibrosarcoma was studied, and the transplantation kinetics of this tumor in mice whose primary tumors had been controlled by radiation were determined. Normal syngeneic C3Hf/Bu mice received the 3-methylcholanthrene-induced tumor at 9-16 wk of age. The mice were immunosuppressed temporarily by 600 rads of whole-body irradiation (WB1) or immunosuppressed permanently by thymectomy plus 900 rads of WB1 followed by reconstitution with syngeneic bone marrow (Tx1R), or were treated iv with *Corynebacterium parvum* (0.25 mg in 0.4 ml/mouse). The radiation dose necessary to achieve TCD50 was lowest (1,530 rads) in mice treated with *C. parvum* prior to irradiation. Increasing values of TCD50 were observed in normal mice, in those given 600 rads WB1 prior to tumor transplantation, and in Tx1R mice: 3,040 rads, 5,080 rads, and 6,450 rads, respectively. Considerable heterogeneity of response in normal and *C. parvum*-treated mice was observed. In many mice in which the tumor had been controlled by irradiation 4 mo previously, and in which four sc sites per mouse were injected with equal numbers of tumor cells, tumors became palpable and subsequently regressed; some mice developed tumors at all sites, while others developed no tumors. In some cases, individual mice rejected large inocula, while others could not reject small inocula. These reactions were not observed in control mice, either normal or those immunosuppressed by 600 rads WB1. (39 refs)

79-6908 Tibial Osteosarcoma Developing on a Myelomatous Focus Sterilized by Radiotherapy. (Fre) Deshayes, P. (Service de Rhumatologie, Hopital de Boisguillaume, F 76230 Boisguillaume, France); Dessauw, P.; Thorel, J. B.; Hemet, J.; Ducastelle, C.; Thomine, J. M.; Graic, Y.; Monconduit, M. *Nouv Presse Med* 8(36): 2907-2908; 1979.

A case of osteosarcoma developing in association with irradiation for myeloma of the tibia in a 25-yr-old man is described. The sternal bone marrow was normal. Light kappa chains were found in the blood and urine. Surgery was followed by telecobalt irradiation of the affected part of the tibia (total dose 3,300 rads in 11 sessions in 17 days) and by chemotherapy with melphalan (2 mg/day for 18 mo, then 30 mg on 5 consecutive days), cyclophosphamide, and vincristine (0.4 mg/day). The patient developed osteosarcoma in the irradiated area of the tibia 8 yr later. While the role of the chemotherapy cannot be ruled out, the osteosarcoma was probably induced by the irradiation. (4 refs)

79-6909 Radiation-induced Fibrosarcoma of the Mandible Following Treatment for Bilateral Retinoblastoma. (Eng) Ferlito, A. (Section Pathology, Dept. Otolaryngology, Univ. Padua, Padua, Italy); Recher, G.; Tomazzoli, L. *J Laryngol Otol* 93(10): 1015-1020; 1979.

The occurrence of a mandibular fibrosarcoma in an 11-yr-old girl treated during her first and fourth years of life for bilateral retinoblastoma is reported. The first course of treatment consisted of enucleation of the left eye followed by irradiation (total dose 3,000 rads) of the right eye and chemotherapy with vincristine and cyclophosphamide. The second course of treatment consisted of irradiation (2,000 rads) followed 3 yr later by surgery for a second

dary cataract. A poorly differentiated malignant mandibular fibrosarcoma showing extensive necrosis was diagnosed when the child was 11 yr old. She died shortly thereafter of neoplastic cachexia. It is concluded that radiation is important in carcinogenesis, but that genetic mutation may play an additional role. (11 refs)

79-6910 Local Damage and Chromosomal Changes After Exposure to Radiocobalt Source. (Cze) Klenner, V. (Institut hygieny a epidemiologie, Srobarova 48, 100 42 Prague 10, Czechoslovakia); Tuscany, R.; Novotna, J.; Sevc, J.; Thomas, J. *Prac Lek* 31(6/7): 230-234; 1979.

A ⁶⁰Co emitter with an activity of about 3 kilocuries dropped out in the course of replacement of the radiation source in the head of an irradiator at an oncological unit. The assembly technician became significantly exposed while trying to reinsert the emitter. He developed acute skin changes and focal necrosis of the left hand, the latter necessitating amputation of the fingers and part of the hand. A film dosimeter recorded the equivalent of 159 rads during the accident. The equivalent whole-body dose, estimated on the basis of chromosome analysis, was 120-160 rads. Chromosome analyses 1-28 mo post-exposure showed a decrease of the dicentric forms from 100% (0.13/cell) to 39% (0.05/cell). Deviations of dicentrics in the particular cells from Poisson's distribution confirmed the assumption of the considerable inhomogeneity of the irradiation. It is stressed that intensive sealed emitters are the most dangerous sources of accidental overexposure. (12 refs)

79-6911 Thermal Keratoses and Squamous Cell Carcinoma in Situ Associated with Erythema Ab Igne. (Eng) Arrington, J. H. (Dermatopathology Service, Moses H. Cone Memorial Hosp., 1200 N. Elm St., Greensboro, NC 27420); Lockman, D. S. *Arch Dermatol* 115(10): 1226-1228; 1979.

A 60-yr-old black woman presented with a large hyperkeratotic lesion and multiple smaller hyperkeratotic papules and plaques on the lower part of her legs in areas of erythema ab igne. Histologic examination of the largest lesion revealed hyperplastic carcinoma in situ; the multiple smaller lesions showed varying degrees of squamous cell atypia and dermal elastosis. These lesions were histologically identical to solar-induced atypia, indicating that squamous cell carcinoma arising in erythema ab igne may be biologically similar to actinic carcinoma. The patient had a history of chronic exposure to heat from sitting close to a coal fire. Clinical and histologic features of these thermal-induced lesions and other types of thermal-induced carcinomas are discussed. (20 refs)

79-6912 Carcinoma of the Hypopharynx as a Late Result of Radiation Treatment. (Ger) Glasenapp, G. B. (Hals-Nasen-Ohren-Klinik, Medizinische Akademie Magdeburg, Leipziger Strasse 44, DDR-301 Magdeburg, E. Germany); Freitag, F. *Laryngol Rhinol Otol (Stuttg)* 58(8): 629-634; 1979.

Two cases of squamous cell carcinoma of the hypopharynx in women who underwent radiation treatment for goiter during 1938-1942 are described. Severe local damage to the skin in both cases indicates that unusually large radiation dosages were given. These cases illustrate the danger of radiation treatment for benign conditions. (24 refs)

PHYSICAL CARCINOGENESIS

- 79-6913 Malignant Peritoneal Mesothelioma Following Radiotherapy for Seminoma of the Testis. (Eng) Stock, R. J. (Inst. Pathology, Case Western Reserve Univ., Cleveland, OH 44106); Fu, Y. S.; Carter, J. R. *Cancer* 44(3): 914-919; 1979.

The establishment of a diagnosis of malignant peritoneal mesothelioma is described in a 66-yr-old male patient who developed the lesion 16 yr after radiation therapy (3,200 rads) for a seminoma of the testis. The cellular similarities between mesothelioma and seminoma, as well as the patient's history, prompted a number of differing initial diagnoses. However, histochemical and ultrastructural evidence was compatible with the diagnosis of mesothelioma; the lesion was only faintly and sporadically PAS-positive, while the original seminoma was strongly PAS-positive; and ultrastructural characteristics included numerous tall microvilli on the free surfaces, tonofibrils, glycogen granules, lipid vacuoles, desmosomes, and intracytoplasmic lumens with microvilli. Historically, histologically, electron microscopically, and by microincineration, there was no evidence of asbestos exposure. The lesion may have occurred as a consequence of prior radiation therapy. (14 refs)

- 79-6914 Recovery Course in Mouse Spleen and Bone Marrow After Continuous Irradiation. (Eng) Mackova, N. (Inst. General Biology, Faculty Sciences, P.J. Safarik Univ., Moyzesova 11, CS - 041 67 Kosice, Czechoslovakia); Praslicka, M. *Folia Haematol (Leipz)* 106(3): 351-357; 1979.

The course of spleen and bone marrow recovery from irradiation was studied in adult male H strain mice continuously irradiated with a dose of 478.5 milli-Gray units (mGy: 50 R; group 1), 957 mGy (100 R; group 2), or 4,785 mGy (500 R; group 3) up to a total dose of 9,570 mGy (1,000 R) over periods of 20, 10, and 2 days, respectively. Parameters of spleen and bone marrow recovery were examined on days 0, 7, 14, 21, 28, and 60 after irradiation. Continuous irradiation caused a 55%-70% decrease in spleen wt immediately after irradiation. In group 1, spleen wt returned to control values by day 28 after irradiation, in group 2 by day 4, and in group 3 was 40% higher than that in controls by day 14. The RBC count in the spleen was decreased by 70%-90% immediately after irradiation but recovered during the postirradiation period. The cell number in the spleen was decreased to 10%-20% in all three groups. In groups 1 and 2, the cell count increased to 80%-90% that of controls on day 28, and in group 3 it was higher than that in controls. Marrow from the femur showed a dose-dependent decrease in cell count following irradiation. In groups 1 and 2, the cell count began to increase immediately after irradiation, but in group 3 it continued to decrease until day 7; it then began to increase and reached control values by day 60. These results indicate that recovery processes in the spleen and bone marrow following irradiation are completed by day 28 and 60, respectively. (19 refs)

- 79-6915 Radiation Carcinogenesis in the Syrian Hamster. (Eng) Stenback, W. A. (Div. Experimental Biology, Baylor Coll. Medicine, Houston, TX); Bryan, M. E.; Trentin, J. J. *Prog Exp Tumor Res* 23: 89-99; 1979.

Recent studies on radiation carcinogenesis in hamsters and hamster tissues are reviewed, and the authors' own studies concerning radiation carcinogenesis and the activation of endogenous viruses are presented. In the latter studies, weanling hamsters were exposed to 200-3,000 R whole-body x-irradiation in different frac-

tionated doses. Of 185 surviving animals, 13 had tumors 193-449 days after the last dose of radiation; most of these were lymphoreticular neoplasms of the spleen and liver. Ten of 11 primary tumors from animals receiving >1,500 R were positive for virus particles by electron microscopy, whereas two tumors from animals receiving lower doses were negative for virus particles. The particle count declined within two to three transplant generations after serial transplantation of virus-positive tumors. The highest tumor incidence was only 12%-13% in each of the four highest total exposure groups. The mouse has been reported to be relatively more susceptible to radiation-induced lymphomagenesis. The hamster's relative resistance may be related in part to increasing levels of relatively radioresistant, lymphomacytotoxic natural killer cells in older hamsters compared with mice. (24 refs)

- 79-6916 Circulating Blocking Factors of Lymphoid-Cell Cytotoxicity in X-Ray-induced Rat Small-Bowel Adenocarcinoma. (Eng) Stevens, R. H. (Radiation Res. Lab., 14 Medical Lab., Dept. Radiology, Univ. Iowa, Iowa City, IA 52242); Brooks, G. P.; Osborne, J. W. *Radiat Res* 80(1): 161-169; 1979.

Circulating blocking factors capable of abrogating cell-mediated immune responses measured by in vitro lymphoid-cell cytotoxicity were identified in the sera of Holtzman outbred rats 6-9 mo after a single exposure of only the temporarily exteriorized, hypoxic ileum and jejunum to x-rays (1,700-2,000 R). These factors were found in the serum of every exposed animal regardless of whether a visibly identifiable small-bowel adenocarcinoma existed or would subsequently develop. Protection of cultured x-ray-induced rat small-bowel cancer cells from destruction by tumor-sensitized lymphoid cells, as measured by the release of lactoperoxidase-catalyzed radioiodinated membrane proteins from the tumor target cells, was conferred by the action of the blocking factors at both effector and target cell levels. The results of this study demonstrate that exposure of only the rat small intestine to ionizing radiation leads to elaboration of circulating factors which will block cell-mediated immune responses directed against cancer cells developing in the exposed tissue. - 79-6917 Radiation-induced Colo-rectal Carcinoma. A Report of Seven Cases. (Eng) Moriya, Y. (Dept. Surgery, Div. Radiology, Natl. Cancer Center Hosp., 5-1-1 Tsukiji, Chuo-ku, Tokyo 104, Japan); Koyama, Y.; Hojo, K.; Ushio, K.; Hirota, T.; Itabashi, M. *Jpn J Clin Oncol* 9(1): 153-161; 1979.

Seven patients who developed colorectal carcinoma following radiation injuries were identified among 880 patients with colorectal carcinoma seen in a Tokyo hospital between 1962 and 1978. The seven patients, six of whom were women, were initially irradiated for epidermoid carcinoma of the cervix (5 cases), epidermoid carcinoma of the vulva (1 case), or carcinoma of the cecum (1 case). The average age of the patients was 42 yr at the time of radiotherapy and 60 yr at the time of diagnosis of secondary colorectal carcinoma (latent period 16-21 yr). Six of the seven patients had metachronous double primary carcinoma and were among a total of 35 such patients in the series of 880. Four of seven radiation-induced tumors were of the localized ulcerating type, two were of the ulcerated infiltrating type, and one was of the diffuse infiltrating type. There were two poorly differentiated adenocarcinoma and two mucinous carcinomas. (14 refs)

- 79-6918 Adenocarcinoma of the Colon Following the Treatment of Wilms Tumor. (Eng) Sabio, H. (Dept. Pediatrics, Univ. Virginia Hosp., Box 386, Charlottesville, VA 22908); Teja, K.; Elkon, D.; Shaw, A. *J Pediatr* 95(3): 424-426; 1979.

The occurrence of an adenocarcinoma of the colon within a field previously irradiated for the treatment of Wilms tumor is reported. The patient, a 12-yr-old boy, had received ^{60}Co (2,100 rads over 14 days) at age 5 mo for a Group I Wilms tumor of the left kidney. Microscopic examination of the mass subsequently found in the splenic flexure of the colon revealed a poorly differentiated adenocarcinoma with areas of large amounts of mucin production. The tumor infiltrated the entire thickness of the bowel wall, was present in the pericolic fat, and had metastasized to one lymph node. The surrounding mucosa exhibited extensive radiation colitis, with areas of ulceration, inflammation, and atrophy. Focal superficial adenomatous change was noted away from the tumor in a few areas. The patient had no known history suggestive of a predisposition for early occurrence of colon carcinoma, eg, polyposis, ulcerative colitis, or a family history of malignancy. (7 refs)

- 79-6919 Cancer of the Colon on an Ileocolonic Anastomosis Prepared in 1954 for Ulcerative Hemorrhagic Rectocolitis. (Fre) Chatelin, C. L. (No affiliation given); Campora, J. L.; Fissore, A.; Fissore, O. *Ann Gastroenterol Hepatol (Paris)* 15(4): 275-276; 1979.

An ileocolonic anastomosis was established in a 25-yr-old woman with ulcerative hemorrhagic rectocolitis in 1954. The patient was in good condition for 23 yr, after which she developed recurrent diarrhea and attacks of abdominal pain. A laparotomy in 1977 revealed ulceration and adenocarcinoma of the anastomosis and ovarian, hepatic, and peritoneal metastases. (no refs)

- 79-6920 Uretersigmoidostomy Followed by Carcinoma of the Colon. (Eng) Recht, K. A. (Dept. Urology, West Virginia Univ. Medical Center, Morgantown, WV 26506); Belis, J. A.; Kandzari, S. J.; Milam, D. F. *Cancer* 44(4): 1538-1542; 1979.

Adenocarcinoma of the colon developing as a late complication of uretersigmoidostomy has been reported with increasing frequency. The case is presented of a patient who developed adenocarcinoma of the colon 28 yr after uretersigmoidostomy for bladder exstrophy and 13 yr after conversion of the uretersigmoidostomy to an ileal conduit. The colonic tumor was documented at postmortem examination to be at the uretersigmoidostomy site. Metastases to the supraclavicular lymph node were histologically identical to the primary tumor. Because of the potential late development of adenocarcinoma of the colon, careful follow-up of patients with uretersigmoidostomies, particularly those performed in childhood, is indicated. Possible mechanisms responsible for the malignant change are discussed. (28 refs)

- 79-6921 Lung Tumors from $\text{PuO}_2\text{-ZrO}_2$ Aerosol Particles in Syrian Hamsters. (Eng) Thomas, R. G. (Toxicology Group, Univ. California, Los Alamos Scientific Lab., Los Alamos, NM 87545); Smith, D. M. *Int J Cancer* 24(5): 594-599; 1979.

Syrian golden hamsters were given $\text{PuO}_2\text{-ZrO}_2$ particles via inhalation and/or Pu-laden ZrO_2 ceramic 10- μm diameter microspheres lodged in the capillary bed of the lung. The mean initial lung burdens ranged from 8 nanoCi to 143 nanoCi for the six experimental groups. Significant numbers of primary lung tumors (5%-50% of animals in each group) were induced by inhalation exposures. Additional α -radiation administered via Pu-laden iv microspheres had little or no effect on tumorigenesis or on the production of nonneoplastic, degenerative changes in the respiratory tract. (19 refs)

- 79-6922 Evaluation of Alpha Radiation-induced Respiratory Carcinogenesis in Syrian Hamsters: Total Dose and Dose-Rate. (Eng) Little, J. B. (Dept. Physiology, Harvard Univ. Sch. Public Health, Boston, MA 02115); Kennedy, A. R. *Prog Exp Tumor Res* 24: 356-369; 1979.

The induction of lung cancer in random bred male Syrian golden hamsters by multiple intratracheal instillations of ^{210}Po was studied. A dose-dependent increase in lung tumors (primarily peripheral tumors classified as combined epidermoid and adenocarcinomas) was found following irradiation of the lung with 15-15,000 rads; the tumor incidence ranged from 9% to 97%. Administration of ^{210}Po on Fe_2O_3 carrier particles resulted in a highly nonuniform distribution of the radiation dose as compared with the homogeneous distribution found following instillation of ^{210}Po in a saline solution. However, the ultimate tumor incidence was the same following administration by either method. Preliminary data indicate that dose-rate (the degree of protraction of the exposure) does not influence tumor induction by similar total radiation doses. However, the instillation procedure itself acts as a cofactor in ^{210}Po lung carcinogenesis. Hamsters appear to be highly resistant to the induction of lung cancer by inhaled α emitters as compared with rats. (30 refs)

- 79-6923 The Influence of Oxidation State on the Absorption of Plutonium from the Gastrointestinal Tract. (Eng) Sullivan, M. F. (Biology Dept., Pacific Northwest Lab., Richland, WA 99352); Ryan, J. L.; Gorham, L. S.; McFadden, K. M. *Radiat Res* 80(1): 116-121; 1979.

The effect of oxidation state on gastrointestinal absorption of plutonium was studied using solutions that either did or did not contain a strong oxidant and animals that either were or were not fasted. No appreciable differences were seen in the absorption of intragastrically injected $^{238}\text{Pu(IV)}$ (0.0003 mg) and $^{238}\text{Pu(VI)}$ (0.0005 mg) by either rats or guinea pigs on a normal diet. To determine if the conditions used in a previous study were responsible for the increased gut absorption of $^{239}\text{Pu(VI)}$, relative to $^{239}\text{Pu(IV)}$, both fasted (18 hr before until 72 hr after Pu administration) and unfasted rats were gavaged with acid soln of $^{239}\text{Pu(VI)}$ nitrate in the presence or absence of the holding oxidant ($\text{K}_2\text{Cr}_2\text{O}_7$). The results indicated that the combination of dichromate and fasting increased absorption about 26-fold. (6 refs)

- 79-6924 Role of Iron in Plutonium-239 Excretion Processes in Different Regions of the Gastrointestinal Tract. (Rus) Shvydko, N. S. (Res. Inst. Radiation Hygiene, Leningrad, USSR); Rushonik, S. I.; Popov, D. K.; Vorozhtsova, L. N. *Radiobiologiya* 19(5): 725-730; 1979.

The effect of iron on Pu239 excretion was studied in albino rats injected iv with plutonium citrate (3.0 μ Ci/mouse). The mice began receiving weekly doses of iron citrate (13.3 mg/mouse, po, 63 days) 2.5 hr after the plutonium injection. Animals were sacrificed 2.5 hr, 7, 14, 27, 42, or 63 days after isotope injection, and the gastric, duodenal, and intestinal contents were analyzed. Iron administration resulted in a two- to eightfold increase in the fraction of radionuclide absorbed by different regions of gastrointestinal tract, but did not change the rate of Pu239 elimination. 79-6925 Sister Chromatid Exchanges in Human Lymphocytes After Exposure to Diagnostic Ultrasound. (Eng) Liebeskind, D. (Dept. Radiology, Albert Einstein Coll. Medicine, Bronx, NY 10461); Bases, R.; Mendez, F.; Elequin, F.; Koenigsberg, M. *Science* 205(4412): 1273-1275; 1979.

The effect of ultrasound on the incidence of sister chromatid exchanges (SCE) was studied in freshly isolated human lymphocytes and in the continuously growing human lymphoblast line SKL-7.

The cells were exposed to diagnostic levels of ultrasound for 30 min between their first and second divisions (48 hr after addition of phytohemagglutinin-16 in the fresh lymphocyte culture and 18 hr after mitogen addition in the lymphoblast line). Fresh lymphocytes and the lymphoblast line showed a small but significant increase in the number of SCEs. These results suggest that ultrasound may not be entirely innocuous. (18 refs)

VIRAL CARCINOGENESIS

- 79-6926 *V-15_B*, an Allele of Chickens for the Production of a Noninfectious Avian Leukosis Virus. (Eng) Robinson, H. L. (Worcester Foundation Experimental Biology, Shrewsbury, MA 01545); Astrin, S. M.; Salazar, F. H. *Virology* 99(1): 10-20; 1979.

Evidence is presented that 15_B chickens have a dominant allele *V-15_B* for the expression of a noninfectious avian leukosis virus. This virus is designated 15_B-ILV. In genetic crosses *V-15_B* cosegregated with *ev 7*, a genetic locus which contains structural genes for virus. The expression of 15_B-ILV was tightly controlled in *V-15_B* cells. The expression of other ALV germ line and infection proviruses was not infected by *V-15_B*. These results suggest that *V-15_B* consists of cis-dominant control sequences as well as structural sequences for 15_B-ILV. 15_B cells also contain a putative allele *Gr-E* which codes for high levels of replication of subgroup E viruses. In genetic crosses *V-15_B* was shown to reside at a distinct genetic locus. (31 refs)

- 79-6927 Low Frequency Production of Recombinant Subgroup E Avian Leukosis Viruses by Uninfected *V-15(B)* Chicken Cells. (Eng) Robinson, H. L. (Worcester Foundation for Experimental Biology, Shrewsbury, MA 01545); Eisenman, R.; Senior, A.; Ripley, S. *Virology* 99(1): 21-30; 1979.

The production of subgroup E viruses by uninfected 15(B) chicken cells was studied. In contrast to the noninfectious avian leukosis virus (15B-ILV) spontaneously produced at estimated frequencies of one event per 10³ cell days by these cells, the E viruses (15B-E) were produced by 15(B) cells at an estimated frequency of one event per 2 x 10⁹ cell days. The frequency of occurrence of 15B-E viruses was affected by the level of expression of *V-15(B)*, an allele for the spontaneous production of 15B-ILV, and by the presence of endogenous viral alleles which constitutively express subgroup E envelope antigens. The proteins of nine independent isolates of 15B-E viruses were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. All isolates had p27 proteins with the distinctive mobility of the p27 of RAV-O, an endogenous virus. Each isolate also had characteristic pairs of p19 related proteins that were similar to pairs of p19 related proteins generated by recombinants of PR-RSV-C, a nondefective avian sarcoma virus, and RAV-O. Since 15B-E isolates occurred in uninfected cells and contained proteins characteristic of RAV-O and recombinants of RAV-O, it is suggested that the 15B-E viruses are recombinants of endogenous viral information. It is further suggested that 15B-ILV and RNAs which contain information for subgroup E envelope antigens are the parents of 15B-E viruses. (26 refs)

- 79-6928 Three New Types of Viral Oncogene of Cellular Origin Specific for Haematopoietic Cell Transformation. (Eng) Roussel, M. (INSERM, Oncologie Moléculaire, Institut Pasteur de Lille, 15 rue C. Guérin F 59000, Lille, France); Saule, S.; Lagrou, C.; Rommens, C.; Beug, H.; Graf, T.; Stehelin, D. *Nature* 281(5731): 452-455; 1979.

Viral oncogenes were sought in seven isolates of replication defective leukemia virus (DLV). Chicken or quail fibroblasts infected with DLV alone were used as a source of viral RNA; when hybridized with purified labeled avian leukemia virus (ALV) transcripts, 22-78% homologous material was found. Less than 3% of RNA from DLV-infected cells was bound to purified *src* gene transcripts of avian sarcoma virus (ASV). Viral clones were obtained by superinfecting nonproducer cells with plaque-purified helper virus RAV-2. When isolates were proven to be oncogenic by a bone marrow transformation test, they were propagated in chicken erythroblasts (avian erythroblastosis virus: AEV), in chicken fibroblasts (MC29), and in live chickens (avian myeloblastosis virus: AMV). Viral RNA, first hybridized to remove ALV genomes, were copied by reverse transcriptase to produce labeled DNA copies (cDNA), which could still hybridize to their corresponding RNA sources. The results showed that cDNAs prepared in this way were specific for the DLV used to produce them, that they were distinct sets of sequences unrelated to each other by cross-hybridization, and that they bore extensive homologous regions to other DLVs (cDNA of MC29 cross-hybridized with CM11, OK10, and MH2 RNA; cDNA of AMV cross-hybridized with E26 RNA). RNA of infected nonproducer cells also retained specific hybridizing properties with the appropriate cDNA of the infecting DLV. All three cDNAs were able to hybridize to DNA isolated from normal chicken DNA sequences at the rate of one or two copies per chicken genome; plateau hybridization values achieved 100%, indicating complete homology of cDNAs with normal chicken DNA. All seven DLV contained all or part of one of three unique sets of nucleotide sequences complementary to cDNA of AEV or MC29 or AMV but not to the *src* gene of ASV. Therefore, all DLV contain portions of the normal chicken genome that may code for transforming factors specific for each of the cell types that each DLV can transform. (28 refs)

- 79-6929 Chicken Hematopoietic Cells Transformed by Seven Strains of Defective Avian Leukemia Viruses Display Three Distinct Phenotypes of Differentiation. (Eng) Beug, H. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); von Kirchbach, A.; Doderlein, G.; Conscience, J. F.; Graf, T. *Cell* 18(2): 375-390; 1979.

Chicken hematopoietic cells transformed in vitro and in vivo by seven strains of replication-defective avian leukemia viruses were assayed for the expression of six erythroid and five myeloid differentiation parameters, including differentiation-specific surface antigens as detected by newly developed antisera. The transformed cells were found to display three distinct phenotypes of differentiation. First, cells transformed by AEV resembled erythroblasts. They expressed heme, globin, carbonic anhydrase and erythrocyte cell surface antigen at low levels, and histone H5 and erythroblast cell surface antigen at high levels. Second, cells transformed by MC29, CM11, OK10, and MH2 viruses had macrophage-like properties. They strongly expressed Fc receptors, phagocytic capacity, and macrophage cell surface antigen, but they only weakly ex-

pressed myeloblast cell surface antigen and were negative for adenosine triphosphatase (ATPase) activity. Third, cells transformed by AMV and E26 viruses resembled myeloblasts in that they weakly expressed Fc receptors, phagocytic capacity, and macrophage cell surface antigen but strongly expressed myeloblast cell surface antigen and ATPase activity. No difference was found between *in vitro*- and *in vivo*-transformed cells in the parameters tested. In light of recent genetic and biochemical evidence, it is concluded that these phenotypes reflect the action of three new types of viral-transforming genes, designated *erb* (erythroblast), *mac* (macrophage), and *myb* (myeloblast). (56 refs)

- 79-6930 Oligoribonucleotide Map and Protein of CMII: Detection of Conserved and Nonconserved Genetic Elements in Avian Acute Leukemia Viruses CMII, MC29, and MH2. (Eng) Bister, K. (Dept. Molecular Biology, Univ. California, Berkeley, CA 94720); Loliger, H. C.; Duesberg, P. H. *J Virol* 32(1): 208-219; 1979.

RNA and protein of the defective avian acute leukemia virus CMII, which causes myelocytomas in chickens, and of CMII-associated helper virus (CMIIAV) were investigated. The RNA of CMII measured 6 kilobases (kb) and that of CMIIAV measured 8.5 kb. By comparing more than 20 mapped oligonucleotides of CMII RNA with mapped and nonmapped oligonucleotides of acute leukemia viruses MC29 and MH2 and with mapped oligonucleotides of CMIIAV and other nondefective avian tumor viruses, the following three segments were distinguished in the oligonucleotide map of CMII RNA: a 5' group-specific segment of 1.5 kb which was conserved among CMII, MC29, and MH2 and also homologous with *gag*-related oligonucleotides of CMIIAV and other helper viruses; an internal segment of 2 kb conserved specifically among CMII, MC29, and MH2 and absent from an otherwise isogenic, nontransforming helper, CMIIAV; and a 3' group-specific segment of 2.5 kb which shared 13 of 14 oligonucleotides with CMIIAV and included *env* oligonucleotides of other nondefective viruses of the avian tumor virus group. This segment and analogous map segments of MC29 and MH2 were not conserved at the level of shared oligonucleotides. CMII-transformed cells contained a nonstructural, *gag* gene-related protein of 90,000 daltons, distinguished by its size from 110,000-dalton MC29 and 100,000-dalton MH2 counterparts. The *gag* relatedness and similarity to the 100,000-dalton MC29 counterpart indicated that the 90,000-dalton CMII protein is translated from the 5' and internal segments of CMII RNA. The existence of conserved 5' and internal RNA segments and conserved nonstructural protein products in CMII, MC29, and MH2 indicates that these viruses belong to a related group, termed the MC29 group. MC29 group viruses differ from one another mainly in their 3' RNA segments and in minor variations of their conserved RNA segments as well as by strain-specific size markers of their *gag*-related proteins. Because the conserved 5' *gag*-related and internal RNA segments and their *gag*-related, nonviral protein products correlate with the conserved oncogenic spectra of the MC29 group and because the internal RNA sequences and nonviral proteins are not found in nondefective viruses, it is proposed that the conserved RNA and protein elements are necessary for oncogenicity and probably are the *onc* gene and *onc* gene products of the MC29 viruses. (34 refs)

Fund, Lincoln's Inn Fields, London, England); Kitchener, G.; Graf, T. *Virology* 98(1): 191-199; 1979.

Nonproducer clones of chicken bone marrow cells and quail embryo cells transformed by avian myelocytomatosis virus strain CMII were isolated. Analysis of [³⁵S]methionine-labeled cell extracts of the nonproducer clones by immune precipitation showed that none of the three viral structural protein precursors, Pr76*gag*, gPr95^{env}, and Pr180^{gag-pol} were synthesized; instead, a 90,000 molecular wt protein (CMII-90K) was isolated. Using specific antisera, this protein was shown to be related to the *gag* gene product, but not to the products of the *pol* or *env* genes. Competition radioimmunoassays showed that nonproducer cells expressed inhibitory activity for p19 but not for p27 or p15. Tryptic peptide analysis of CMII-90K, Pr76^{gag}, gPr95^{env}, and the β -subunit of the viral reverse transcriptase confirmed the immunological data demonstrating that the CMII-90K protein contained the p19 tryptic peptides plus peptides that were specific for CMII and not related to *env* or *pol* gene products. It is concluded that the CMII-90K protein could be involved in cell transformation, especially since the tryptic peptide analysis indicated that it contains CMII-specific peptides. (39 refs)

- 79-6932 Localization of the ASV *src* Gene Product to the Plasma Membrane of Transformed Cells by Electron Microscopic Immunocytochemistry. (Eng) Willingham, M. C. (NCI, Bethesda, MD 20205); Jay, G.; Pastan, I. *Cell* 18(1): 125-134; 1979.

The cellular location of the *src* gene product (p60^{src}) of the Schmidt-Ruppin strain of avian sarcoma virus (ASV) was determined by electron microscopic immunocytochemistry in Schmidt-Ruppin ASV-transformed NRK cells, and the amount of the protein in different regions of the cell was quantified. The protein was concentrated on the inner surface of the plasma membrane, particularly under ruffles, and it was highly concentrated on the inner surface of the membrane near junctions connecting adjacent cells. Small amounts of p60^{src} were detected in the cytoplasm and in the perinuclear Golgi region of the cell. No significant localization was detected in control NRK cells or in NRK cells transformed by the Kirsten strain of murine sarcoma virus. The presence of p60^{src} on the inner surface of the plasma membrane indicates that the changes in cell growth, cell shape, and cell membrane structure noted in ASV-transformed cells are due to an initial action of p60^{src} at the cell membrane. (15 refs)

- 79-6933 Inhibition of the Transformation-specific Kinase in ASV-transformed Cells by N- α -Tosyl-L-Lysyl Chloromethyl Ketone. (Eng) Richert, N. (Div. Cancer Biology, Diagnosis, Lab. Molecular Biology, NCI, Bethesda, MD 20205); Davies, P. J.; Jay, G.; Pastan, I. *Cell* 18(2): 369-374; 1979.

The ability of N- α -tosyl-L-lysyl-chloromethyl ketone (TLCK) to inhibit the transformation-specific kinase of avian sarcoma virus (ASV)-transformed chick embryo fibroblasts (CEF) was studied. When CEF transformed with the Schmidt-Ruppin strain of ASV were treated with 0.1 mM TLCK, the kinase activity was reduced by 60% within 2 hr and by 80% after 8 hr, and it continued to remain at low levels for up to 40 hr when TLCK was present. At 24 hr after TLCK treatment, the transformed cells had reverted to a normal phenotype. When TLCK was removed, the kinase activity rose slowly over a period of several hr, the reappearance of enzyme activity corresponding with the reversion of the cells to the

- 79-6931 Cells Transformed by Avian Myelocytomatosis Virus Strain CMII Contain a 90K *gag*-related Protein. (Eng) Hayman, M. J. (Dept. Tumour Virology, Imperial Cancer Res.

transformed phenotype within 24-48 hr. The effect of TLCK *in vivo* was concentration dependent and specific. Other serine protease inhibitors had no effect on the kinase activity. At low concentrations (0.03 mM), N- α -tosyl-L-phenylalanyl chloromethyl ketone (TPCK) was partially inhibitory ($\leq 20\%$), but at higher concentrations it was extremely toxic to the CEF and could not be tested. The inhibition by TLCK was not due to its ability to inhibit protein synthesis. TLCK and TPCK, but not phenylmethylsulfonyl fluoride, inhibited kinase activity when added directly to cell extracts, but the concentrations required to produce 50% inhibition were fivefold higher than those required *in vivo*. The data suggest that kinase has an important role in transformation and offer a biochemical rationale for treatment of tumors with TLCK. (15 refs)

- 79-6934 Two Avian Sarcoma Virus Mutants with Defects in the DNA Polymerase-RNase H Complex. (Eng) Moelling, K. (Max-Planck Inst. für Molekulare Genetik, 1000 Berlin 33, W. Germany); Friis, R. R. *J Virol* 32(2): 370-378; 1979.

Two avian sarcoma virus mutants exhibiting different phenotypes were analyzed for the properties of their RNA-dependent DNA polymerase and RNase H activities. LA 338, a complex multiple mutant with at least one lesion each in transformation and replication functions, had a purified RNA-dependent DNA polymerase-RNase H complex which was twofold more thermolabile than that from the wild-type parent. The ability of the enzyme to respond to synthetic template-primers was lost more rapidly than was the response to native RNA as template. The mutant enzyme could not be protected from inactivation by the addition of synthetic template-primers. LA 672 showed a "late"-acting block in replication which affected only production of progeny by infected cells grown at the nonpermissive temperature. The purified DNA polymerase-RNase H complex of LA 672 was not thermolabile; rather, progeny grown at the nonpermissive temperature yielded purified enzyme with a 20-fold-reduced specific activity in both DNA polymerase and RNase H. Furthermore, the content of reverse transcriptase protein in such noninfectious progeny did not appear to be significantly diminished since immunologically active enzyme could be demonstrated in a competition test for anti-reverse transcriptase antibody and since β and α subunits of reverse transcriptase could be identified after polyacrylamide gel electrophoresis of partially purified enzyme preparations. The amounts of β and α from the mutant were about twofold lower. (20 refs)

- 79-6935 Immune Response to the *src* Gene Product in Mice Bearing Tumors Induced by Injection of Avian Sarcoma Virus-transformed Mouse Cells. (Eng) Parsons, S. J. (Dept. Microbiology, Univ. Virginia Medical Sch., Charlottesville, VA 22908); Riley, S. C.; Mullen, E. E.; Brock, E. J.; Benjamin, D. C.; Kuehl, W. M.; Parsons, J. T. *J Virol* 32(1): 40-46; 1979.

A single sc injection of 10^7 live cells of the highly tumorigenic avian sarcoma virus (Schmidt-Ruppin strain, subgroup D)-transformed BALB/c line into BALB/c mice resulted in the production of an antiserum specific for the avian sarcoma virus gene product pp60*src*. All sera taken from mice 3 wk after tumor cell injection contained antibodies to pp60*src*. Immunoprecipitation experiments showed that all sera precipitated pp60*src* from Schmidt-Ruppin-infected chicken cells, but only a portion of these sera precipitated pp60*src* from chicken cells infected with other strains of avian sarcoma virus (Prague and Bratislava-77). Analysis of the

cross-reactivity patterns of these antisera demonstrated a minimum of three to four antigenic determinants on pp60*src*. These findings should facilitate the production of monoclonal antibodies to pp60*src*, which in turn will provide highly specific probes for further investigations into the structure and function of this protein. (14 refs)

- 79-6936 The *src* Gene Product of Transformed and Morphologically Reverted ASV-infected Mammalian Cells. (Eng) Collett, M. S. (Dept. Pathology, Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO 80262); Brugge, J. S.; Erikson, R. L.; Lau, A. F.; Krzyzek, R. A.; Faras, A. J. *Nature* 281(5728): 195-198; 1979.

The *src* gene products in avian sarcoma virus (ASV)-transformed European field vole (*Microtus agrestis*) cells and morphologically normal revertant subclones of these cells were compared. Both the transformed and revertant cells contained the sarcoma gene product, a 60,000-mol wt phosphoprotein (pp60*src*) with an associated protein kinase activity. The *src* gene product in both transformed and revertant cells was phosphorylated to a similar extent but the pp60*src* protein in the revertant clones showed a slightly slower electrophoretic mobility than those from the transformed clones. The pp60*src* proteins present in the revertant clones may represent an altered *src* gene product since the pp60*src* proteins from transformed vole and chicken cells comigrated under the same conditions. One-dimensional peptide analyses of 35 S-methionine-labelled pp60*src* with *Staphylococcus aureus* V8 protease indicated that the pp60*src* C-terminal V8 protease peptide in the revertant cell lines had a slower electrophoretic mobility which represented a stable genetic change. No correlation could be made between the concentration of the *src* protein or the specific activity of the pp60*src* protein kinase and the transformed or morphologically reverted state of the ASV-infected cells. The results suggest that the presence of protein kinase activity in itself is not sufficient to induce morphological transformation. Since the revertant cell lines are tumorigenic, the results also indicate that one of the phenotypic parameters of cellular transformation can be expressed in the absence of another. (19 refs)

- 79-6937 Identification of a Rous Sarcoma Virus Transformation-related Protein in Normal Avian and Mammalian Cells. (Eng) Rohrschneider, L. R. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA 98104); Eisenman, R. N.; Leitch, C. R. *Proc Natl Acad Sci USA* 76(9): 4479-4483; 1979.

Immunoprecipitation with rabbit antitumor serum containing broad spectrum antibodies to a 60,000-dalton protein (pp60^{src}) product of avian sarcoma virus (ASV) was used to examine normal uninfected frog, chicken, rat, human, and *Drosophila* cells for a similar phosphoprotein. The frog, chicken, rat, and human, but not the *Drosophila*, cells contained such a protein, designated pp60. Peptide maps of [35 S]methionine-labeled pp60 and pp60^{src} indicated major similarities as well as some differences in amino acid composition, and peptide maps of 32 P-labeled proteins demonstrated that the phosphopeptides of all endogenous pp60 molecules tested were identical. However, some differences were noted between the phosphopeptide patterns of pp60 and viral pp60^{src}. The kinase activity associated with pp60^{src} was measured in the immunocomplex and resulted in the transfer of radioactive phosphorus from [γ - 32 P]ATP to the immunoglobulin heavy chain as well as to an 80,000-dalton phosphoprotein. The pp60s of

chicken, rat, and human origin also contained an associated kinase activity. These results are consistent with the notion that the pp60 molecules are the protein products of endogenous *sarc* sequences found in vertebrate cells. (28 refs)

- 79-6938 Characterization of RNA Polymerases from Rous Sarcoma Virus-induced Mouse Ascites Sarcoma Cells. (Eng) Misumi, H. (Health Lab. Okayama Prefecture, 1-1-17, Furugyo-cho, Okayama 703, Japan); Oda, T. *Acta Med Okayama* 33(2): 91-102; 1979.

RNA polymerase was extracted from the Schmidt-Ruppin strain of Rous sarcoma virus (SR-RSV)-induced C3H/He mouse ascites sarcoma cells (SR-C3H) and separated into RNA polymerases I and II by DEAE-Sephadex chromatography. The main component of RNA polymerase I after phosphocellulose chromatography was 1b. Polymerase activities obtained by DEAE-Sephadex chromatography were dependent on added DNA and inhibited by RNase. The reaction was enhanced 50% by 10 mM 2-mercaptoethanol or 0.5 mM dithiothreitol. Divalent cations were required for the reaction, with the optimal concentration of Mn^{++} ions being approx 2 mM and of Mg^{++} 5-15 mM. RNA polymerase I had optimal activity at concentrations of 0.05 M ammonium sulfate $(NH_4)_2SO_4$ and RNA polymerase II at 0.1 M $(NH_4)_2SO_4$. At ionic strengths >0.2 M $(NH_4)_2SO_4$, the activities of both polymerases were strongly inhibited. At 0.05-0.1 M $(NH_4)_2SO_4$, RNA polymerase I transcribed native DNA most actively, and RNA polymerase II transcribed denatured DNA most actively. Partial digestion of DNA by DNase I enhanced RNA synthesis by RNA polymerases I and II. The initiation complexes of RNA polymerases I and II with native DNA were more stable against high salt concentration than with denatured DNA. These results suggest that the higher affinity of RNA polymerase II for denatured DNA was nonspecific or nonspecific termination of the reaction occurred. (26 refs)

- 79-6939 Relationship Between Inhibition of Protein Methylase I and Inhibition of Rouse Sarcoma Virus-induced Cell Transformation. (Eng) Enouf, J. (Institut de Chimie des Substances Naturelles, Centre National de Recherche Scientifique, 91190 Gif-sur-Yvette, France); Lawrence, F.; Tempete, C.; Robert-Gero, M.; Lederer, E. *Cancer Res* 39(11): 4497-4502; 1979.

The effects of more than 30 S-adenosylhomocysteine (SAH) analogs with modifications on the purine ring, the sugar moiety, or the 5'-side chain on protein methylase I (PMI) activity and on focus-formation in Rous sarcoma virus (RSV)-infected cells were studied in secondary cultures of chicken embryo fibroblasts. Among the compounds tested which inhibited PMI, all were competitive inhibitors with respect to S-adenosylmethionine (SAM). The analogs could be grouped into three categories: Group A, good inhibitors, containing 15 compounds all of which are modified in the 5'-side chain; Group B, medium inhibitors, containing 9 analogs with several types of chemical modifications; and Group C, poor inhibitors, containing 13 compounds. All the good inhibitors of PMI strongly prevented RSV-induced cell transformation, but the reverse was not always true. The inhibitory effect of these analogs was similar on enzymes from normal and transformed cells; no significant variation of the inhibition was observed after purification of PMI. These studies suggest a role of PMI in cell transformation. (48 refs)

- 79-6940 Relationship Between the Production of Rous Sarcoma Virus in Hamster Cells and Cell Cycle Phase. (Rus) Cherepantseva, E. A. (Lab. Virus Etiology Tumors, Inst. Epidemiology and Microbiology, Moscow, USSR); Shevliagin, V. I. *Tsitologiya* 21(10): 1189-1193; 1979.

The features of Rous sarcoma virus (RSV) production in transformed embryonal hamster cells (strain 23x) were studied. RSV production was detected only in cells in the log phase of growth; the number of infective centers on day 3 of culturing was 120/ml, compared with 4/ml on day 4, ie, during the stabilization of cell culture. Complete inhibition of cell proliferation caused by nonlethal x-irradiation (1,000 R) resulted in a decrease in or complete termination of RSV production. Blocking DNA synthesis in 23x cells caused a 10-fold decrease in RSV production. RSV production was associated with mitosis and the G1 stage of the cell cycle. (14 refs)

- 79-6941 Inhibition of Rous Sarcoma Virus Replication by 2-Deoxyglucose and Tunicamycin: Identification of an Unglycosylated *env* Gene Product. (Eng) Stohrer, R. (Dept. Microbiology, Medical Center, Univ. Alabama, Birmingham, AL 35294); Hunter, E. *J Virol* 32(2): 412-419; 1979.

2-Deoxyglucose and tunicamycin, both inhibitors of glycosylation, depressed the synthesis of infectious Rous sarcoma virus (RSV) by more than 100-fold. Under the same conditions only a two- to threefold decrease in the production of virus particles was observed. The noninfectious particles had a lower density (1.145 g/ml) in isopycnic sucrose gradients and lacked gp85 and gp37, the two virion glycoproteins found on infectious virions. The four internal structural proteins of the virus, p27, p19, p15, and p12, appeared to be assembled normally into the noninfectious virus. Polypeptides related to the RSV glycoproteins were immunoprecipitated from pulse-labeled RSV (Prague strain, subgroup B)-transformed cells. The polyprotein precursor to gp85 and gp37, pr95(gp), was the major protein precipitated from untreated cells; it was absent in both tunicamycin- and 2-deoxyglucose-treated cells, with a new polypeptide of mol wt 57,000-58,000 being the major species precipitated. This product was unstable in tunicamycin-treated cells and was degraded during a 2-hr chase; in 2-deoxyglucose-treated cells, on the other hand, the polypeptide appeared to be more stable and underwent partial glycosylation. The synthesis and processing of pr76, the polyprotein precursor to the internal structural proteins of the virion, occurred normally in both treated and untreated cells. It was concluded that the unglycosylated *env* gene product is a polypeptide of mol wt 57,000-58,000. (34 refs)

- 79-6942 Effect of Immunologic Intervention on In Vivo Murine Rous Sarcoma Virus Tumorigenesis. (Eng) Banks, R. A. (Dept. Biological Sciences, Hampton Inst., Hampton, VA 23668); Babcock, G. F.; Whitmore, A. C.; Haughton, G. *J Natl Cancer Inst* 63(6): 1423-1431; 1979.

The effect of immunologic manipulation on the development of primary murine Rous Sarcomas (PRS) was studied following the injection of Rous sarcoma virus-induced chicken tumor material (RCTM) into neonatal mice of different strains. Heterologous antithymocyte serum (ATS) treatment beginning at 7 or 21 days of age tripled and nearly doubled, respectively, the incidence of PRS, but treatment at 21 days significantly prolonged the mean latency of the tumors. Lymphoid cells from syngeneic adult mice immunized with allogeneic PRS had no effect when injected into 1-

day-old mice, but immune lymph-node cells (LNC) injected 1 wk after birth (preceded by RCTM injections on day 1 of life) significantly increased the tumor incidence. LNC and spleen cells (SC) from syngeneic adult mice that had been inoculated with RCTM at birth but had developed tumors by 200 days of age (VT) decreased tumor incidence when administered on day 1 but not on day 7. Normal adult SC and LNC had no effect when given on day 1 but significantly increased tumor incidence when given on day 7. Serum from adult immune, VT, and tumor-positive mice decreased the PRT incidence when given on days 1 and 7. The offspring of immune mothers were less susceptible than those of normal mothers. The offspring of passively immunized mothers given serum from immune females during pregnancy were more susceptible than controls. RCTM-inoculated mice appeared to be susceptible only to immunologic manipulations that reduced PRT incidence during the first few days of life. (32 refs)

- 79-6943 Analysis of the *src* Gene of Sarcoma Viruses Generated by Recombination Between Transformation-defective Mutants and Quail Cellular Sequences. (Eng) Wang, L. H. (Rockefeller Univ., New York, NY 10021); Moscovici, C.; Karess, R. W.; Hanafusa, H. *J Virol* 32(2): 546-556; 1979.

Inoculation of a transformation-defective (td) mutant of Schmidt-Ruppin strain Rous sarcoma virus strain A (SR-A) that retained a small portion of the *src* gene induced tumors in quails after about 1 mo. A td mutant with nearly complete deletion of the *src* gene did not induce tumors. The avian sarcoma viruses recovered from 5/5 quail tumors (rASV-Q) were biologically similar to the viruses (rASV-C) isolated from chicken tumors induced by the same td mutants. Both rASV-Q and rASV-C transformed cells in culture with similar focus morphology, and induced tumors 7-14 days after inoculation into chickens or quails. The sequences of rASV-Q RNA genomes were compared to those of the parental td virus (SR-A) and rASV-C. All five rASV-Q isolates had identical *src* sequences, which differed from those of SR-A and rASV-C. Two of 13 *src*-specific oligonucleotides found in rASV-Q were not found in either SR-A or rASV-C RNA. The *src* regions of SR-A and/or rASV-C RNA's also contained some oligonucleotides which were not found in rASV-Q. There were no differences in sequences outside the *src* region in any of these viruses. The rASV-Q-infected cells also had a 60,000-dalton protein, which was specifically precipitable by rabbit serum against SR-D-induced tumors. The facts that *src* sequences were essentially the same for rASV's from one species of bird and different for rASV's obtained from another species provide conclusive evidence that cellular sequences from normal host tissues were inserted into the viral genome, supplying to the resulting recombinant viruses the genetic information for cell transformation. (33 refs)

- 79-6944 Circular Forms of DNA Synthesized by Rous Sarcoma Virus In Vitro. (Eng) Clayman, C. H. (Dept. Microbiology, Univ. Minnesota Medical Sch., Minneapolis, MN 55455); Mosharrafa, E. T.; Anderson, D. L.; Faras, A. J. *Science* 206(4418): 582-584; 1979.

The presence of circular mature forms of retrovirus DNA was demonstrated by electron microscopic analysis of the DNA product synthesized by detergent-disrupted preparations of Rous sarcoma virus in vitro. The identification of such circular DNA indicates that virions of retroviruses contain all the components necessary to facilitate the complete synthesis of mature forms of

viral DNA and therefore provide a useful system to delineate the molecular mechanisms involved in their synthesis. (14 refs)

- 79-6945 Viral Transformation of Chick Myogenic Cells. The Relationship Between Differentiation and the Expression of the SRC Gene. (Eng) Moss, P. S. (Dept. Zoology, Univ. California, Berkeley, CA 94720); Honeycutt, N.; Pawson, T.; Martin, G. S. *Exp Cell Res* 123(1): 95-105; 1979.

Chick embryo presumptive muscle cells transformed at 35 C with a temperature-sensitive mutant of Rous sarcoma virus, tsLA29, do not undergo myogenic differentiation but revert to a phenotypically normal state and fuse into myotubes when shifted to 41 C. Studies of this phenomenon revealed the activation of myosin synthesis, the appearance of myosin messenger RNA active in vitro, and acetylcholinesterase (AChE) synthesis following a shift from 35 C to 41 C. The activation of myosin synthesis also occurred in cultures prevented from fusing by calcium deprivation. However, after myosin synthesis had been initiated at 41 C, it could not be suppressed by shifting the cultures back to 35 C. [³H]Thymidine labeling and autoradiography demonstrated that DNA synthesis in tsLA29-infected myoblasts ceased within 24 hr after the shift to 41 C. A kinetic analysis of the withdrawal of these cells from the cell cycle indicated that at least a fraction of the cells do not need to traverse a complete cell cycle prior to terminal differentiation. (51 refs)

- 79-6946 The Influence of Host Adaptation of Rous Sarcoma Virus on the Transfecting Activity of its DNA Provirus. (Eng) Hlozanek, I. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, 166 10 Prague 6, Czechoslovakia); Svoboda, J.; Dostalova, V.; Mach, O. *J Gen Virol* 45(1): 139-147; 1979.

In previous studies, mammalian cells transformed with either Prague strain Rous sarcoma virus of subgroup C (XC cells) or Schmidt-Ruppin strain Rous sarcoma virus of subgroup D (RSCH cells) yielded virus upon fusion with chick cells. Virus was also rescued by transfection of DNA from these cells onto chick cells. However, virus rescue did not occur upon transfection of duck cells, and fusion with duck cells led to virus rescue only from RSCH and not from XC cells. In the present study this restriction on duck cells was investigated. The nondefective Prague strain of Rous sarcoma virus of subgroup C (PR-RSV-C) was adapted for efficient replication in duck embryo cells (daPR-RSV-C) by long-term passage in vitro. However, a second PR-RSV-C isolate, rescued from the rat XC sarcoma line (XC DNA 940 virus), failed to adapt to growth in duck cells. When transformed with daPR-RSV-C, which replicates in duck cells as well as in brown leghorn embryo (BLEF) cells, duck cells yielded DNA that transfects fresh duck cells, in contrast to DNA isolated from chicken or duck cells transformed with parental PR-RSV-C. (31 refs)

- 79-6947 Selective Replication of Transformation-defective Avian Sarcoma Virus Mutants in Duck Embryo Fibroblasts. (Eng) Shimakage, M. I. (Dept. Tumor Viruses, Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suita City, Osaka, Japan); Kamahora, T.; Hakura, A.; Toyoshima, K. *J Gen Virol* 45(1): 99-105; 1979.

VIRAL CARCINOGENESIS

Differences in the replicating capacity of sarcoma viruses and their transformation-defective (*td*) mutants are described. When an avian sarcoma virus (ASV), subgroup C Bratislava 77 (B77-C), was inoculated into duck embryo fibroblast cultures (DEF) at a multiplicity of infection (moi) of 0.02, its replication was retarded by about 3 days compared with that in chick embryo fibroblast cultures (CEF). A *td* mutant was isolated during this period of retardation. Unlike the sarcoma virus, this *td* mutant replicated in both DEF and CEF with no retardation, even at a low moi. The subgroup C Prague strain of Rous sarcoma virus (PR-C), which can infect DEF, also replicated in DEF slower than its *td* mutant, *td*PR-C, at a moi of 0.02. (20 refs)

- 79-6948 Tryptic Peptide Analysis of Avian Oncovirus *gag* and *pol* Gene Products. (Eng) Rettenmier, C. W. (Rockefeller Univ., New York, NY 10021); Karess, R. E.; Anderson, S. M.; Hanafusa, H. *J Virol* 32(1): 102-113; 1979.

Radiolabeled tryptic peptides of the *gag* and *pol* gene products of avian oncoviruses [Rous-associated virus 2 structural proteins and the Pr76(*gag*) and P180(*gag-pol*) proteins] were examined in Rous-associated virus 2-infected chicken embryo cells. The methionine- and cysteine-containing tryptic peptides of virion internal structural proteins were present in both Pr76(*gag*) and P180(*gag-pol*), suggesting that there was no loss of *gag* gene-coding sequences during the generation of P180(*gag-pol*). No overlap of *gag* and *pol* gene structural information was detected. Analysis of intermediates in the processing of Pr76(*gag*) and translation inhibition mapping with pactamycin yielded the following order of structural proteins within the Rous-associated virus 2 Pr76(*gag*) precursor: NH₂-p19-p12-p27-p15-COOH. The *gag* and *pol* sequences missing in the endogenous gs⁺ P120 protein of uninfected gs⁺ chicken cells were identified by comparison with those of Rous-associated virus 2 P180(*gag-pol*). (29 refs)

- 79-6949 Cell Fusion for Genetic Analysis of Two Nonconditional Rous Sarcoma Virus Replication Mutants. (Eng) Steimer, K. S. (Dept. Surgery, Children's Hosp. Medical Center, Boston, MA 02115); Boettiger, D. *J Virol* 32(1): 175-186; 1979.

Procedures for characterizing replication-defective viruses in nonpermissive mammalian cells were developed and applied to three nonvirogenic Rous sarcoma virus (RSV)-transformed mammalian cell lines: B4, a line of Bryan virus-transformed hamster cells; and two Schmidt-Ruppin D virus-RSV transformed rat cell lines, LR3/1 and LR3/2. Cell fusion was used to study virus complementation. The three cell lines fused with helper virus-infected chicken cells and the host range of the rescued virus examined, tested for complementation by fusion with chicken cells exhibiting various patterns of endogenous virus expression, fused with chicken cells infected with the temperature-sensitive replication mutant LA334 and assayed for complementation of permissive and nonpermissive temperatures, and tested for complementation of defective viruses in other RSV-transformed mammalian cell lines by fusing pairs of nonvirogenic cell lines and permissive chicken cells. Based upon these complementation studies, it was concluded that B4 virus is defective only in the *env* gene, LR3/1 virus is an absolute mutant in the *gag* and/or *pol* genes, and LR3/2 virus is a leaky *env* mutant. Clones of LR3/1 and LR3/2 virus-infected chicken cells were established, and the results obtained from the characterization of these viruses in permissive avian cells substantiated the conclusions reached in the fusion-rescue studies. (50 refs)

- 79-6950 Relationship Between Rous Sarcoma Virus-induced Expression of Membrane Antigen and Phenotypic Transformation. (Eng) Comoglio, P. M. (Istituto di Anatomia Umana Normale, Univ. Torino, Corso Massimo d'Azeglio, 52, 10126 Turin, Italy); Pani, B.; Prat, M.; Tarone, G.; Montibragadin, C. *Cancer Res* 39(11): 4744-4748; 1979.

Rous sarcoma virus-transformed hamster BHK fibroblasts express a virus-induced cell surface antigen not detectable in cells either transformed by unrelated viruses or infected by transformation-defective strains of Rous sarcoma virus. To clarify whether this antigen plays any role in the process of malignant transformation or is expressed at the cell surface only as a consequence of the acquisition of the transformed phenotype, antigen expression at the cell surface was investigated in Rous sarcoma virus-transformed BHK cells treated with dibutyl cyclic adenosine 3':5'-monophosphate (dibutyl cAMP) and in parental BHK cells transiently transformed by the tumor promoter phorbol myristate acetate (PMA). In the dibutyl cAMP-monophosphate-treated cells, most of the parameters of the transformed phenotype were reverted to normality while the product of the transforming gene was still present, and virus-induced cell surface antigen was expressed. In the mirror experiment, this antigen was not expressed by phenotypically transformed but genetically normal PMA-treated cells. It was concluded that the tumor membrane antigen studied is intimately associated with the expression of the function(s) controlled by the transforming gene. (33 refs)

- 79-6951 Failure to Confirm Evidence for a Nonviral Tumor-specific Surface Antigen in Avian Retrovirus-transformed Cells. (Eng) Phillips, E. R. (Dept. Pathology, Queen's Univ., Kingston, Ontario K7L 3N6, Canada); Perdue, J. F. *J Natl Cancer Inst* 63(4): 991-994; 1979.

Triton X-100 or Nonidet P40-deoxycholate extracts of [³H]fucose-labeled Rous sarcoma virus-transformed chick embryo fibroblasts were examined by indirect immunoprecipitation for the presence of a tumor-specific neoantigen of 100,000 daltons. Extracts were incubated with immune IgG from Rous tumor-sensitized chickens, and the resultant antigen-antibody complexes were precipitated with rabbit anti-chicken IgG and analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Radioactivity appeared between the migration positions of proteins having mol wts of 65,000 and 95,000 daltons and at about 30,000 daltons. These antigens were group-specific, and their precipitation was inhibited by competition with extracts from cultured fibroblasts that had been infected with a nontransforming avian leukosis virus. They were not precipitated with IgG from unimmunized chickens or chickens immunized with the culture supernatants of uninfected chick embryo fibroblasts. In contrast to recently reported results, the present results did not confirm the existence of a tumor neoantigen different from that associated with viral components. However, the tumor-specific antigen may have existed on the cell surface but was not preserved in these detergent extracts. (22 refs)

- 79-6952 Cellular and Humoral Immune Reactivity to Tumor-associated Antigens in Chickens Infected with Rous Sarcoma Virus. (Eng) Hall, M. R. (Dept. Microbiology, Mayo Clinic, Rochester, MN 55901); Qualtiere, L. F.; Meyers, P. *J Immunol* 123(3): 1097-1105; 1979.

The time course of the development of cellular reactivity to Rous sarcoma virus (RSV) tumor-associated antigens over time was

determined using a leukocyte blastogenesis assay. WBC reactivity to mitogens in RSV-injected birds was also investigated. Cellular immunity to 3 M KCl extracts of avian tumor virus (ATV)-infected chick embryo fibroblasts (CEF), principally to those extracts containing structural components of the virus envelope, developed 3-5 wk after injection (during tumor growth and regression) and then declined, although the immune response could be restimulated by virus rechallenge. Responses to nonviral tumor-specific surface antigen (TSSA) were weak except after RSV rechallenge. There were no differences in phytohemagglutinin (PHA) responsiveness between the WBC of RSV-injected birds and control birds, but responses to pokeweed mitogen (PWM) were sometimes elevated in RSV-injected animals. Humoral reactivity as measured by an isotopic antiglobulin test (IAT) also seemed to correlate well with the presence of virus envelope antigens (VEA) on infected indicator cells and appeared before antiviral neutralizing antibody. These data show that during the primary response, major immune reactivity in RSV-injected birds is directed against VEA and that TSSA is most immunogenic when VEA is also present. (54 refs)

- 79-6953 Deletion Mutant of the Bratislava-77 Strain of Rous Sarcoma Virus Containing a Fusion of the Group-specific Antigen and Envelope Genes. (Eng) Dierks, P. M. (Dept. Microbiology, Institut für Molekularbiologie I, Universität Zürich, Honggerberg, 8093 Zürich, Switzerland); Highfield, P. E.; Parsons, J. T. *J Virol* 32(2): 567-582; 1979.

A deletion mutant of the Bratislava-77 strain of Rous sarcoma virus (B77-RSV) containing a large deletion (3,500 nucleotides) in the polymerase region of the viral genome was detected and characterized. The deletion mutant accumulated after multiple passages of B77-RSV on Peking duck embryo fibroblasts. In each of two independently passaged B77 stocks, >77% of the viral subunits contained the deletion after 7-8 passages. It was determined, by ribonuclease T1-resistant oligonucleotide fingerprint analysis of viral RNA, direct RNA sequencing, and analysis of virus-specific proteins synthesized in vivo and in vitro, that the deletion encompasses the 3' terminus (approx 250 nucleotides) of the *gag* gene, all of the *pol* gene, and some (probably <500 nucleotides) of the *env* gene. (42 refs)

- 79-6954 Evidence for the Identity of Shared 5'-Terminal Sequences Between Genome RNA and Subgenomic mRNA's of B77 Avian Sarcoma Virus. (Eng) Stoltzfus, C. M. (Dept. Microbiology, Univ. Iowa, Iowa City, IA 52242); Kuhnert, L. K. *J Virol* 32(2): 536-545; 1979.

The polyribosomal fraction from chicken embryo fibroblasts infected with B77 avian sarcoma virus contained 38S, 28S, and 21S virus-specific RNA's, in which sequences identical to the 5'-terminal sequence (101 bases) of the 38S genome RNA were present. The only polyadenylic acid-containing RNA with 5' sequences which was detected in purified virions had a sedimentation coefficient of 38S. The findings are consistent with the hypothesis that a leader sequence derived from the 5' terminus of RNA is spliced to the bodies of the 28S and 21S messenger RNA's (mRNA's), both of which are derived from the 3' terminal half of 38S RNA. Several experiments showed that the majority of the subgenomic, intracellular virus-specific mRNA's contained the entire 101-base 5'-terminal sequence of the 38S genome RNA. In addition, a small population of virus-specific RNA's contained either a shortened 5' leader sequence or additional splicing in the terminal 101 bases. (32 refs)

- 79-6955 Transfer of Natural Resistance to Marek's Disease (JMV) with Non-Immune Spleen Cells. I. Studies of Cell Population Transferring Resistance. (Eng) Lam, K. M. (Dept. Microbiology, Sch. Veterinary Medicine, Tuskegee Inst., Tuskegee, AL 36088); Linna, T. J. *Int J Cancer* 24(5): 662-667; 1979.

The mechanism of age-related resistance to the JMV line of Marek's disease virus (MDV) was studied using SC chickens. Seven-wk-old birds were significantly more resistant to ip JMV cell challenge than were newly hatched chicks ($p < 0.002$). Chickens receiving 5×10^7 normal spleen cells from untreated 8-wk-old donors also showed significantly lower mortality from tumors than those not receiving spleen cells ($p < 0.002$). Spleen cells from thymectomized and sham-thymectomized birds were equally effective in this respect, and spleen cells treated with anti-T serum and complement were able to protect newly hatched chicks from JMV malignancy. Significant protection was also afforded by spleen cells from bursectomized donors and donors depleted of both the T- and B-cell populations. Significant protection was given by spleen cells from which both phagocytic and adherent cells had been removed ($p = 0.002$). Thus, the cell transferring resistance does not appear to belong to the major T-cell, B-cell, or macrophage populations but instead seems to be part of the functionally heterogeneous 'third cell' population. (23 refs)

- 79-6956 Pheasant Virus DNA Polymerase is Related to Avian Leukosis Virus DNA Polymerase at the Active Site. (Eng) Bauer, G. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706); Temin, H. M. *J Virol* 32(1): 78-90; 1979.

The DNA polymerase from Amherst pheasant virus (APV), a member of the pheasant virus species of retroviruses, was compared to the DNA polymerases of avian leukosis viruses (ALV) and a reticuloendotheliosis virus (spleen necrosis virus; SNV). Immunoglobulin inhibition tests and competition immunoassays showed that APV and ALV DNA polymerases are closely related at their active sites. The determinants common to their active sites are not shared by SNV DNA polymerase. In a species-specific radioimmunoassay, both APV and SNV DNA polymerases were grossly different from ALV DNA polymerase. The specificity of the relationship of the active sites of APV and ALV DNA polymerases was confirmed by a heterologous radioimmunoassay. These data indicate that pheasant viruses are evolutionarily linked to ALV. (21 refs)

- 79-6957 Detection of Polymorphism in BALB/c Leukemia Viruses with Mouse Antisera. (Eng) Brown, J. P. (Fred Hutchinson Cancer Res. Center, Seattle, WA 98104); Boiuchi, M.; Nowinski, R. C. *J Virol* 32(1): 345-349; 1979.

Three murine antisera, which recognize primarily type-specific antigenic determinants on both the major core protein, p30, and the major envelope proteins, gp70 and p15(E), of BALB/c endogenous murine leukemia viruses (MuLV), were investigated in detail. Antisera prepared in C57BL/6 mice against the AKR leukemia K36 reacted with the gp70, p15(E), and p30 proteins of MuLV. Certain pools of the C57BL/6 anti-AKR K36 serum contained antibodies which serologically distinguished the p30 proteins of N-ecotropic, B-ecotropic, and xenotropic BALB/c MuLV. Antisera prepared in BALB/c mice against the BALB/c sarcoma 1315 contained antibodies that reacted with a type-specific antigen of the 1315 MuLV gp70 that is not found on other BALB/c

MuLV. The normal sera of multiparous BALB/c mice contained antibodies that reacted with gp70 and p15(E) proteins of ecotropic MuLV. Sera from some of these mice contained antibodies that serologically distinguished the gp70 of N-ecotropic and B-ecotropic BALB/c viruses. These results emphasize the utility of mouse antisera in the serological typing of MuLV. Furthermore, the antigenic differences observed in the p30 and gp70 proteins should be of particular use in the future analysis of recombinant BALB/c MuLV. (30 refs)

- 79-6958 Polymorphism of B-Tropic Leukemia Viruses from BALB/c Mice: Association of a p30 Antigen with N-Versus B-Tropism. (Eng) Tress, E. (Memorial Sloan-Kettering Cancer Center, New York, NY 10021); O'Donnell, P. V.; Camulari, N.; Ellis, R. W.; Fleissner, E. *J Virol* 32(1): 350-355; 1979.

Comparison of a number of murine leukemia virus clones by sodium dodecyl sulfate-polyacrylamide gel electrophoresis revealed extensive protein polymorphism among B-tropic, but not N-tropic, isolates from BALB/c mice, particularly in migration of p30 proteins. A type-specific radioimmunoassay for p30 was developed which uniformly discriminated all B-tropic viruses from N-tropic viruses of BALB/c origin. N- and B-tropic viruses of C57BL/6 and AKR *Fv-1(b/b)* origin could also be distinguished by this assay. (37 refs)

- 79-6959 Monoclonal Antibodies Against Murine Leukemia Viruses: Identification of Six Antigenic Determinants on the p15(E) and gp70 Envelope Proteins. (Eng) Lofstrom, M. E. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA 98104); Stone, M. R.; Tam, M.; Burnette, W. N.; Pinter, A.; Nowinski, R. C. *Virology* 98(2): 336-350; 1979.

Twenty-three independently derived hybrid cell lines that produced monoclonal antibodies against the envelope proteins of murine leukemia virus (MuLV) were characterized. These hybrid cells were prepared by the polyethylene glycol-mediated fusion of a mouse myeloma cell line with lymphocytes from mice immunized with allogeneic MuLV-producing leukemia cells. The 23 cell lines were cloned and inoculated into syngeneic mice for the production of ascites fluids that contained high-titered (20-75 mg/ml) monoclonal antibodies. Six serologically distinct specificities were detected when these ascites fluids were tested on a broad panel of MuLV and non-murine retroviruses. Prototype cell lines producing monoclonal antibodies representative of each pattern of reaction were selected for further study. In immune precipitation assays, each prototype antibody reacted with viral envelope proteins; three of these identified antigenic determinants on p15(E), while three others identified antigenic determinants on gp70. The p15(E) antigenic determinants were shared by a diverse panel of MuLV. One of these p15(E) antigenic determinants was also found in feline leukemia virus. The gp70 antigenic determinants, on the other hand, had a more restricted distribution and were found in only selected isolates of MuLV. (26 refs)

- 79-6960 Suppression of the Immune Response in Tumor-bearing Mice. I. Response to Virus-producing Tumor Cells and Non-Virus-producing Tumor Cells. (Eng) Bluestone, J. A. (Lab. Herpes Virus Infections, Memorial Sloan-Kettering

Cancer Center, 1275 York Ave., New York, NY 10021); Lopez, C. *J Natl Cancer Inst* 63(5): 1215-1220; 1979.

To determine the tumor antigen(s) responsible for inducing suppressor cells and to study the cell interactions leading to the suppression of the cell-mediated immune response, suppression induced by virus-producing and -nonproducing syngeneic tumors was investigated. In addition, athymic nude mice inoculated with syngeneic tumor cells were studied. Spleen cells from mice inoculated with syngeneic murine sarcoma virus (MuSV)-transformed tumor cells demonstrated a depressed response in the mixed leukocyte reaction. Mice inoculated with virus-producing tumor cells demonstrated two types of suppression. First, an early suppression was shown to be mediated by an adherent suppressor T-cell on the basis of its sensitivity to Thy 1.2 antiserum plus complement and the absence of the early suppression in T-cell-deficient nude mice. This suppression may have been induced in response to viral antigens associated with cell surface antigens (modified self-antigens) or viremia, because it was not induced by a non-virus-producing tumor cell line. Second, late suppression was shown to be T-cell-independent by its presence in nude mice and by its resistance to γ -irradiation and Thy 1.2 antiserum plus complement. In addition, late suppression was present in mice inoculated with a nonproducer clone of MuSV-transformed cells. This finding suggests that viral antigens and/or viremia is not required for the induction of late suppression. (26 refs)

- 79-6961 Organization of Mouse Mammary Tumor Virus-specific DNA Endogenous to BALB/c Mice. (Eng) Cohen, J. C. (Dept. Microbiology and Immunology, Tulane Univ. Sch. Medicine, New Orleans, LA 70112); Majors, J. E.; Varmus, H. E. *J Virol* 32(2): 483-496; 1979.

Restriction endonucleases were used to prepare physical maps of the mouse mammary tumor virus (MMTV)-specific DNA endogenous to the BALB/c mouse strain. The mapping was facilitated by the DNA transfer procedure, using complementary DNAs specific for the whole and for the 3' terminus of MMTV RNA to detect fragments containing viral sequences. Arrangement of the fragments into physical maps was accomplished through sequential digestions with two or three enzymes, preparative isolation of *EcoRI* fragments containing viral sequences, and comparisons of virus-specific fragments derived from the DNA of several mouse strains. It was found that most of the MMTV-related DNA in the BALB/c genome is organized into two units (II and III) which strongly resemble proviruses acquired upon horizontal infection with milk-borne strains of MMTV and other retroviruses. These units contain approx 6.0×10^6 M(r) of apparently uninterrupted viral sequences; they bear redundant sequences totaling at least 700 to 800 base pairs at their termini, and these include sequences derived from the 3' end of MMTV RNA. Units II and III are closely related in that they share 12 of 14 recognition sites for endonucleases, but cellular sequences flanking units II and III are dissimilar by this criterion. The remainder of the MMTV-related DNA endogenous to BALB/c mice is found in a single unit (unit I) with a complexity of approx 2×10^6 M(r); the structure of unit I was not further defined. These results support the hypothesis that endogenous proviruses have been acquired by infection of germinal tissues with MMTV. The physical maps can be used in studies of the natural history of mammary tumorigenesis to identify the MMTV genomes endogenous to BALB/c mice. (37 refs)

- 79-6962 In Vivo and In Vitro Phosphorylation of Murine Mammary Tumour Virus Proteins. (Eng) Dion, A. S.

(Dept. Molecular Biology, Inst. Medical Res., Copewood Street, Camden, NY 08103); Fout, G. S.; Pomenti, A. A. *J Gen Virol* 44(3): 669-678; 1979.

In vitro and in vivo phosphorylation of murine mammary tumor virus (MMTV), a type B RNA virus, were compared. The protein kinase activity associated with MMTV catalyzed in vitro phosphorylation of endogenous virus polypeptides. This kinase activity required a divalent metal cation, a nonionic detergent, and was stimulated in the presence of dithiothreitol. Exogenous cyclic AMP was not required. The ^{32}P -labeled products of the in vitro reaction were completely sensitive to pronase digestion, and the phosphate was attached mainly by phosphomonoester linkage to serine residues. As determined by sodium dodecyl sulfate-polyacrylamide gel electrophoresis, heterogeneous labeling of major and minor virus polypeptides was observed under in vitro conditions. In contrast, the in vivo labeling of type B virus produced by a continuous cell line (MuMT-73), established from pooled mammary adenocarcinomas of Balb/c \times C $_3$ H mice, demonstrated specific phosphoproteins associated with MMTV. The major phosphorylated proteins were found to have mol wt 18,000 and 12,000 (p18 and p12) after isolation by molecule sieving chromatography and analysis by gel electrophoresis. (24 refs)

79-6963 Hormonal Regulation of Murine Mammary Tumor Virus RNA Expression During Mammary Tumorigenesis in BALB/c Mice. (Eng) Pauley, R. J. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX 77030); Medina, D.; Socher, S. H. *J Virol* 32(2): 557-566; 1979.

The effects of glucocorticoids and prolactin on murine mammary tumor virus (MuMTV) RNA expression were investigated in preneoplastic outgrowth lines and mammary tumors in BALB/c mice. Hyperplastic alveolar nodules (HAN) and a ductal hyperplasia (DH) were induced in virgin BALB/c mice by prolonged hormonal stimulation, treatment with 7,12-dimethylbenz(a)anthracene (DMBA), or a combination of the two. Mice bearing HAN or DH outgrowth lines and mammary tumors arising from them were treated with glucocorticoids or prolactin, and MuMTV RNA was quantitated by hybridization with a representative complementary DNA probe specific for MuMTV RNA. Prolactin treatment did not increase MuMTV RNA in the BALB/c HAN or DH outgrowth lines or tumors. MuMTV RNA increased after glucocorticoid treatment in the C3, C4, and C5 HAN outgrowth lines (derived from DMBA-induced HAN) and in tumors that arose from the D1 and D2 (derived from hormonally induced HAN), the C4 and C5, and the CD8 DH (derived from DMBA-induced DH) outgrowth lines. No increase in MuMTV RNA with glucocorticoid treatment was observed in the D1 or D2 HAN outgrowth lines, in the CD8 DH outgrowth line, and in tumors that arose from the C3 HAN outgrowth line. The ability of glucocorticoids to stimulate MuMTV expression was specific, as indicated by the dose dependence and hormone specificity of the response. Glucocorticoid treatment did not increase the level of type C viral RNA in the majority of hormone- or DMBA-induced HAN outgrowth lines or tumors. These observations suggest that glucocorticoids may influence MuMTV expression during mammary tumorigenesis in BALB/c mice. (39 refs)

79-6964 Polyprotein Precursors to Mouse Mammary Tumor Virus Proteins. (Eng) Anderson, S. J. (Dept. Biology, Univ. Texas System Cancer Center, M.D. Anderson Hosp. and

Tumor Inst., Houston, TX 77030); Naso, R. B.; Davis, J.; Bowen, J. M. *J Virol* 32(2): 507-516; 1979.

Seven proteins, ranging in mol wt from 10,000 to 55,000 daltons (gp55, gp33, p25, pp20, p16, p12, and p10), were identified by sodium dodecyl sulfate polyacrylamide gel electrophoresis of mouse mammary tumor viruses (MMTV) obtained from the culture medium of GR mouse mammary adenocarcinoma cells. Each of these proteins contained methionine and leucine. The major viral phosphoprotein was pp20. Immunoprecipitation studies showed that gp55 and gp33 arise from a common precursor (gPr76env). The MMTV glycoproteins and gPr76env could be labeled with radioactive leucine and glucosamine; labelling with fucose indicated that synthesis of gp33 and gp55 may involve a minor, high-mol wt, and heavily fucosylated polyprotein (gPr79env). A 78,000-dalton protein doublet (Pr78gag) had antigenic determinants in common with at least p25 and p12. Tryptic mapping confirmed the precursor-product relationship of Pr78gag and p25 and indicated that Pr78gag shares peptides with p12 and p10. The results of chase experiments indicated that gPr76env has a more rapid turnover than Pr78gag in cultured GR cells; labeled gp55 was formed (presumably from the cleavage of gPr76env or gPr79env, or both), but no significant amounts of p25 or other gag proteins were observed, even though Pr78gag appeared to chase and viral particles appeared in the chase medium. These results may indicate the existence of an efficient precursor processing, or may reflect the precursor product relationship between the A and B particles of MMTV. The low levels of p25 in infected cells suggest that maturation occurs coincidentally with budding of the virus. (40 refs)

79-6965 Impaired Maturation of Mouse Mammary Tumor Virus Precursor Polypeptides in Lymphoid Leukemia Cells, Producing Intracytoplasmic A Particles and No Extracellular B-Type Virions. (Eng) Nusse, R. (Dept. Virology, Antoni van Leeuwenhoekhuis, Plesmanlaan 121, 1066 CX Amsterdam, Netherlands); van der Ploeg, L.; van Duijn, L.; Michalides, R.; Hilgers, J. *J Virol* 32(1): 251-258; 1979.

Processing of mouse mammary tumor virus polypeptides was investigated in a transplanted thymic lymphoma cell line of the GR strain (GRSL) maintained in vivo in ascites form and in vitro as a suspension culture. GRSL cells produce clusters of intracytoplasmic A particles and are virtually deficient in the production of mature extracellular B-type particles. As control, a mammary tumor cell line of the same mouse strain capable of complete virion synthesis was used. The kinetics of viral polypeptide synthesis were studied by pulse labeling with various isotopes (including ^{35}S and ^{32}P), followed by immunoprecipitation of cell lysates with monospecific antisera to the major mouse mammary tumor virus gag and env proteins, p27 and gp52, respectively. Both the primary gag and env precursor polypeptides were synthesized in the GRSL cells, but their conversion into viral proteins was impaired. The major gag precursor, Pr73(gag), was stable over a period of 8 hr; and mature viral core polypeptides could not be detected. Also, the highly phosphorylated intermediates in the proteolytic processing of Pr73(gag) in virus-producing cells were absent in GRSL cells. By immunoprecipitation, Pr73(gag) was detected in a GRSL particle fraction with the density of intracytoplasmic A particles. The precursor for envelope proteins, Pr73(env), was turned over without the generation of mature viral envelope components gp52 and gp36. The in vivo-transplanted ascites GRSL cells, however, expressed gp52 on the cell surface together with a 73,000-dalton polypeptide, as indicated by cell surface iodination and immunoprecipitation. VIRAL CARCINOGENESIS

- 79-6966 Cultivation of Mouse Mammary Tumor Cells Derived from DD/Tbr. II. Characteristics of MuMTV-producing Cell Lines. (Eng) Iwai, M. (Dept. Parasitology, Nara Medical Univ., Nara, Japan); Iwai, Y.; Takamori, Y.; Okumoto, M.; Murata, Y. *Annu Rep Radiat Cent Osaka Pref* 19: 95-100; 1978.
- Three clonal sublines isolated from the established cell line DDMT-761, derived from a spontaneous mammary tumor in a DD/Tbr mouse, were designated DDMT-762, -763, and -764. Cell lines 762 and 763 were epithelioid, and their growth properties were similar to those of the parental cell line. Cell line 764 was fibroblastic and was the fastest-growing of the four cell lines. The epithelial cell lines could be maintained for 2 mo or more by changing medium without subculturing, but the 764 cells tended to detach from the culture dish 10-14 days after plating. The modal chromosome number for cell lines 761, 762, and 763 was 80; that of DDMT-764, 75-79. The amount of virus in the culture fluid was determined by measuring RNA-dependent DNA polymerase activity. Peak virus production by cell lines 762, 763 and 764 was 175%, 62% and 112% of that in parental cell line 761, respectively. Buoyant density of murine mammary tumor virus in sucrose was 1.17 and was clearly distinguishable from the 1.15 of murine leukemia virus. The released virus particles were type B, as confirmed by electron microscopy. (8 refs)
- 79-6967 Viral Expression and Immunogenicity of CBA Mammary Carcinomas and Their Hybrid Lines with an L-Cell Derivative (A9HT). (Eng) Kuzumaki, N. (Dept. Tumor Biology, Karolinska Institutet, Stockholm, Sweden); Ber, R.; More, I. A.; Cochran, A. J.; Wiener, F.; Klein, G. *Eur J Cancer* 15(10): 1253-1261; 1979.
- Somatic cell hybrids were obtained by Sendai virus-mediated fusion of a highly tumorigenic variant of L-cell subline A9 of C3H mouse origin (A9HT) and CBA mammary carcinomas SBfnHA and SBfnHC (carried in CBAT6 mice). The presence of biarmed A9HT marker chromosomes confirmed hybridity. Fusion was not between A9HT and stroma cells from CBAT6 mice, as shown by the absence of the T6 marker in both hybrid cell lines (both were spindle cell carcinomas). A9HT and SBfnHA cells expressed mammary tumor virus (MTV)-associated antigens, including major structural component gp52, and murine leukemia virus (MuLV) structural components gp71 and p30 on the cell surface. SBfnHC expressed only gp71. The SBfnHA/A9HT hybrid lost the surface expression of MTV gp52 and MuLV p30, and showed less expression of gp71 than SBfnHA cells. The SBfnHC/A9HT hybrid showed more expression of gp71 than SBfnHC cells. Sensitivity to the cytotoxicity of anti-H-2^k sera was unchanged in all parental and hybrid cell lines. Experiments in CBA mice immunized with heavily irradiated cells and challenged with viable tumor cells showed that the SBfnHA/A9HT hybrid was less immunogenic than SBfnHA, whereas the SBfnHC/A9HT hybrid was slightly more immunogenic than the very poorly immunogenic SBfnHC parent cell line. These results are consistent with the possibility that MTV- and MuLV-associated cell surface antigens influence the immunogenicity of CBA mammary carcinomas. (14 refs)
- 79-6968 A Human Breast Tumor Cell Line (BT-474) that Supports Mouse Mammary Tumor Virus Replication. (Eng) Lasfargues, E. Y. (Inst. Medical Res., Copewood Street, Camden, NJ 08103); Coutinho, W. G.; Dion, A. S. *In Vitro* 15(9): 723-729; 1979.

A human breast tumor cell line (BT-474) derived from an invasive ductal carcinoma was experimentally infected with a mouse mammary tumor virus from the RIII strain (RIII-MuMTV). The virus that replicated in the human cells was characterized as a murine virus by immunofluorescence, electron microscopy and the presence of a specific RNA-directed DNA polymerase; the cells themselves were human according to karyotype and isoenzyme migration patterns. It was concluded that human cells are susceptible to RIII-MuMTV and can eventually support its replication. (22 refs)

- 79-6969 Mouse Mammary Tumor Virus Genome Expression in Chemical Carcinogen-induced Mammary Tumors in Low- and High-Tumor-Incidence Mouse Strains. (Eng) Dusing-Swartz, S. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX 77030); Medina, D.; Butel, J. S.; Socher, S. H. *Proc Natl Acad Sci USA* 76(10): 5360-5364; 1979.
- Mouse mammary tumor virus (MMTV) involvement in 7,12-dimethylbenz[a]anthracene (DMBA)-induced mammary tumorigenesis was investigated in BALB/c and (BALB/cfC3H mouse strains (having low and high mammary tumor incidences, respectively) which contain endogenous MMTV integrated into the cellular genome. BALB/cfC3H mice are also infected with exogenous MMTV-S (a virulent, milk-transmitted form), which is responsible for a higher incidence of mammary tumors in breeding females. Administration of DMBA (1 mg/wk for 6 wk) to virgin mice of both strains resulted in a moderate frequency of mammary tumors within 40 wk after treatment. No significant differences were found in DMBA-induced tumor incidences at 18 wk (6% and 7%) or at 38 wk (29% and 36%) in BALB/c or BALB/cfC3H mice, respectively. Tumors were assayed for the presence of MMTV RNA by hybridization using MMTV-specific complementary DNA and by immunohistochemical staining utilizing antibodies against MMTV 52,000-dalton glycoprotein, gp52, and 28,000-dalton internal protein, p28. Of 16 BALB/c tumors assayed, 11 did not contain detectable levels of MMTV RNA, while the remaining 5 tumors contained only low levels (0.0005-0.0010%). MMTV RNA was not detected in 5 of 27 BALB/cfC3H tumors; the other BALB/cfC3H tumors contained quantities of MMTV RNA ranging from 0.0006 to 0.4170%. Most BALB/cfC3H tumors with detectable levels of MMTV RNA also synthesized viral proteins gp52 and p28. Thus, expression of the complete MMTV genome is not a prerequisite for maintenance of the tumor phenotype in DMBA-induced mammary tumors in either BALB/c or BALB/cfC3H virgin mice under 1 yr of age. (26 refs)
- 79-6970 Sequence Homology of Nucleic Acids from Human Breast Cancer Cells and Complementary DNA's from Murine Mammary Tumor Virus and Mason-Pfizer Monkey Virus. (Eng) Das, M. R. (Tata Inst. Fundamental Res., Homi Bhabha Road, Colaba, Bombay-400 005, India); Mink, M. M. *Cancer Res* 39(12): 5106-5113; 1979.

Both murine mammary tumor virus (MMTV)- and Mason-Pfizer monkey virus-specific sequences were present simultaneously in nucleic acids isolated from some human breast tumors and from MCF-7 cells, a well-characterized human breast cancer line. Carefully characterized long complementary DNA transcripts were used in the molecular hybridization experiments. The available data suggest that when homology is detected with one of the mammary tumor probes, the other also generally shows

homology. Among all the complementary DNA-RNA hybrids, only three, all MMTV hybrids, showed T_m values (temperatures at which 50% of the total counts were eluted) close to 80 C. The rest of the hybrids were low melting with shallow slopes for their critical temperature curves, indicating partial and imperfect hybrids in the majority of cases. Low levels of weak hybrid formation were also detectable with the tumor DNA's. It cannot be ascertained from the present experiments whether the hybridizing sequences from Mason-Pfizer monkey virus and MMTV code for specific viral functions in their natural hosts. Annealing experiments using gene specific complementary DNA's would be required for full characterization of these sequences. (32 refs)

- 79-6971 Mice with Spontaneous Mammary Tumors Develop Type-specific Neutralizing and Cytotoxic Antibodies Against the Mouse Mammary Tumor Virus Envelope Protein gp52. (Eng) Schochetman, G. (Biological Carcinogenesis Program, Frederick Cancer Res. Center, Frederick, MD 21707); Arthur, L. O.; Long, C. W.; Massey, R. J. *J Virol* 32(1): 131-139; 1979.

Sera from C3H mammary tumor-bearing mice were shown to contain cytotoxic antibodies for mouse mammary tumor virus (MMTV)-producing cells by ^{51}Cr release in a complement-dependent serum cytotoxicity assay. The cytotoxic antibodies could be absorbed by purified C3H MMTV gp52 and C3H MMTV-infected cat cells [C3H (MMTV) CrFK] containing cell surface MMTV gp52. However, purified MMTV p27 and uninfected CrFK cat cells were negative. Absorption of the sera with GR (MMTV) CrFK cells also removed all of the cytotoxicity, whereas absorption with RIII (MMTV) CrFK cells was negative, even though all three infected cat cells contained equivalent amounts of gp52. The same C3H cytotoxic sera also neutralized the focus-forming capacity of a C3H MMTV pseudotype of Kirsten sarcoma virus containing MMTV gp52. In contrast, sera from mammary tumor-bearing GR and RIII mice did not neutralize the pseudotype. Furthermore, neutralization could be achieved only by anti-gp52 but not by anti-gp36, -p27, -p14, or -p10 C3H MMTV sera. The gp52's of C3H, GR, and RIII MMTV could also be distinguished by using a type-specific competition radioimmunoassay employing ^{125}I -gp52 of C3H MMTV and a hyperimmune rabbit anti-C3H MMTV serum. To demonstrate these differences directly, the primary structure of gp52 on the surface of the C3H, GR, and RIII (MMTV) CrFK cells was studied. Two-dimensional tryptic peptide maps of the cell surface lactoperoxidase-catalyzed iodinated gp52's revealed a greater number of peptides common to the gp52's of C3H and GR MMTV's than to RIII MMTV gp52. These results demonstrate that gp52 is a major target antigen for both cytotoxic and neutralizing antibodies, that the cell surface and virion-associated gp52's of C3H, GR, and RIII MMTV contain both group- and type-specific determinants, and that C3H and GR MMTV gp52's are antigenically more related to each other than to RIII MMTV gp52. Furthermore, C3H mammary tumor-bearing mice develop type-specific antibodies capable of recognizing unique gp52 determinants and, therefore, are able to distinguish the gp52 of C3H MMTV from the gp52's of GR and RIII MMTV. (25 refs)

- 79-6972 Mouse Mammary Tumor Virus Infections: Viral Expression and Tumor Risk. (Eng) Altrock, B. W. (Biological Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD 21701); Cardiff, R. D. *J Natl Cancer Inst* 63(4): 1075-1080; 1979.

Tumor risk status in individual naturally infected BALB/cC3H and BALB/c mice given injections of murine mammary tumor virus (MuMTV) was related to the level of viral antigen in their milk. Two distinct groups of MuMTV-infected mice were identified. The milk of one group contained high viral antigen levels ($\geq 100 \mu\text{g/ml}$), whereas the milk of the other group exhibited low levels ($\leq 3 \mu\text{g/ml}$). Mice that exhibited high levels developed tumors by 17 mo of age, whereas those with low levels did not. Viral expression levels in mice having high risks of tumor development were also related to the length of the latency period preceding overt tumor development. The tumor risk potential of naturally infected mice was frequently that of their mothers. Various doses of MuMTV were injected into BALB/c mice, and the resulting infections differed in latency period, level of viral expression, and potential for neoplastic transformation. (27 refs)

- 79-6973 Expression of MuMTV Antigens in Rabbits and Rats Infected with MuMTV. (Eng) Westenbrink, F. (Radiobiological Inst. TNO, P.O. Box 5815, 2280 HV Rijswijk, Netherlands); Koornstra, W. *Virology* 98(2): 493-496; 1979.

Female rabbits and rats were infected with murine mammary tumor virus (MuMTV) as neonates and later subjected to breeding. Milk samples were collected and tested in competition radioimmunoassays for the MuMTV-antigens gp52 and p28. gp52 was expressed in the milk of 3/8 rats and 1/10 rabbits. p28 was detected in only 2/5 milk samples positive for gp52. (24 refs)

- 79-6974 Abelson Antigen is Expressed on Hematopoietic Spleen Colony-forming Cells from Mice Carrying the Av-2^s Virus Sensitivity Gene. (Eng) Risser, R. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI 53706). *Proc Natl Acad Sci USA* 76(10): 5350-5354; 1979.

The relationship between Av-2 locus and the expression of Abelson antigen was studied in BALB/c x C57BL/6 recombinant inbred mouse strains. Antisera that contained antibody to Abelson antigen were cytotoxic for the spleen colony-forming cells (CFU-S) of adult bone marrow from BALB/c mice. Absorption tests with appropriate tissues and direct cytotoxic tests with bone marrow CFU-S from several mouse strains confirmed that the sensitivity of BALB/c CFU-S to lysis by anti-Abelson-antigen antisera was due to expression of Abelson antigen. Spleen or bone marrow from BALB/c mice undergoing hematopoietic regeneration amplified Abelson antigen expression; no expression of Abelson antigen was observed on regenerating C57BL/B6 bone marrow or spleen. The presence of Abelson antigen on bone marrow cells of seven recombinant inbred strains coincided with the inheritance of sensitivity alleles at the Av-2 locus, a gene that determines susceptibility to Abelson murine leukemia virus (A-MuLV) lymphoma induction. If Av-2 controls expression of Abelson antigen in uninfected mice, then the function of this gene in sensitivity to A-MuLV disease should reflect the physiologic role of Abelson antigen in hematopoietic differentiation. A function consistent with the expression of this determinant is that of a cell surface structure associated with the proliferation and differentiation of particular hematopoietic pathways. (33 refs)

- 79-6975 In Vitro Properties of FBR Murine Osteosarcoma Virus (40650). (Eng) Lee, C. K. (Div. Biological and

Medical Res., Argonne Natl. Lab., Argonne, IL 60439); Chan, E. W.; Reilly, C. A.; Pahnke, V. A.; Rockus, G.; Finkel, M. P. *Proc Soc Exp Biol Med* 162(1): 214-220; 1979.

The in vitro biological properties of the osteosarcoma virus FBR, which was originally isolated from a ^{90}Sr -induced osteosarcoma in an X/Gf mouse, were studied. The virus complex consisted of a transforming component, murine sarcoma virus (MuSV), and a nontransforming component, murine-associated virus (MuAV). Foci of cells transformed by FBR-MuSV(MuAV) were late appearing and consistently showed single-hit focus titration patterns. The isolate was infectious only for murine cells, and it showed distinct b tropism. A clone of transformed cells yielding high-titered sarcoma-rich virus was propagated for the large-scale production of the new virus. Tissue-culture-derived RBR-MuSV(MuAV) possessed osteosarcomagenic properties comparable to those of the parent virus. (26 refs)

- 79-6976 Comparison of the Biological Effects of Anemia Inducing and Polycythemia Inducing Friend Virus Complex. (Eng) Steinheider, G. (Institut für Molekularbiologie und Biochemie, Freien Universität Berlin, Arnimallee 22, D-1000 Berlin, W. Germany); Seidel, H. J.; Kreja, L. *Experientia* 35(9): 1173-1175; 1979.

The biological effects of anemia inducing (FV-a) and polycythemia inducing (FV-p) Friend virus complexes were studied in DBA/2 and BALB/c mice. During leukemogenesis, spleen wt, spleen cell numbers, and reticulocyte numbers increased following infection with either virus. However, the increase was delayed and reticulocytosis less pronounced following FV-a infection than following FV-p infection. Femur cell numbers were moderately increased in FV-a-infected, but not FV-p-infected, mice. At day 8 after infection, the hematocrit was elevated in mice infected with FV-p and slightly reduced in those infected with FV-a; the hematocrit levels continued to diverge with time after infection. Thus, leukemogenesis appeared to be delayed in FV-a-infected mice compared with FV-p-infected mice after injection of comparable quantities of virus. No erythropoietin-independent erythroid precursors (CFU-EI), which are characteristic for FV-p-induced leukemia, were found in the leukemic spleen or bone marrow of FV-a-infected mice. The observed differences, especially the lack of CFU-EI in FV-a-infected mice, might be due to differences in the helper virus component of the FV complex. (16 refs)

- 79-6977 Role of Virus-associated Antigen on Xenogenized Tumor Cell Surface in Production of Antibody Against Tumor-associated Antigen. (Eng) Moriuchi, T. (Lab. Pathology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Kita-15-jo, Nishi-7-chome, Kita-ku, Sapporo 060, Japan); Kobayashi, H. *Gann Monogr Cancer Res* 23: 65-72; 1979.

The augmentation of the humoral antibody response to virus-infected tumors and the role of virus-associated antigen (VAA) in the production of antitumor antibody were studied. Friend-virus-infected chemically induced rat fibrosarcomas (FV-KMY-17) were incubated with antisera against tumor-associated antigen (TAA), VAA, or histocompatibility antigen (Rw). Modulation of TAA occurred rapidly, whereas Rw was modulated very slowly, suggesting that TAA and Rw have a different mobility on the cell surface. Antigenic modulation of VAA was induced by a different mechanism involving shedding of the antigen-antibody complex.

FV-KMT-17 was incubated with antiserum against TAA and antisera against VAA or Rw plus complement. Inhibition of lysis was observed with anti-VAA but not with anti-Rw, suggesting that there is an association between TAA and VAA but not between TAA and Rw. Immunization with FV-KMT-17 or non-virus-infected KMT-17 produced the same primary antibody response against TAA. In the secondary response, however, immunization with FV-KMT-17 produced a significantly higher antibody level than immunization with KMT-17. TAA and VAA may associate to form immunogenic units, with VAA functioning as a helper determinant. (7 refs)

- 79-6978 Susceptibility of Japanese Mouse Strains to Murine Leukemia Viruses. (Eng) Hoshino, H. (Dept. Oncology, Inst. Medical Science, Univ. Tokyo, Shirogane-dai, Minato-ku, Tokyo 108, Japan); Yamamoto, T. *Jpn J Exp Med* 49(4): 293-294; 1979.

Susceptibility to the murine leukemia viruses (MuLV) was investigated in the following Japanese mouse strains: FM, KK, KOMA, NC, RR, SII, SS, and TES. All strains were susceptible to infection with both N- and NB-tropic MuLV, but they showed different degrees of resistance to B-tropic MuLV. The genotypes of these strains appeared to be *Fv-1nn* and *Fv-4ss*. Two- to three-month old mice of each of the test strains and of strains DDD, C57BL/6, and C3H were inoculated ip with 0.2 ml of a 10% extract of spleen infected with N-tropic Friend leukemia virus. All strains except C57BL/6 developed splenomegaly. The genotype of C57BL/6 has been demonstrated to be *Fv-2rr*, indicating that the other strains carry the genotype *Fv-2ss* and *Fv-4ss*. Embryo cells of the eight test strains were completely resistant to infection with xenotropic murine sarcoma-leukemia virus complex, as assessed by focus formation. (10 refs)

- 79-6979 Protein Composition of a Defective Murine Sarcoma Virus Particle Possessing the Enveloped Type-A Morphology. (Eng) Pinter, A. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); deHarven, E. *Virology* 99(1): 103-110; 1979.

The protein composition of a noninfectious murine sarcoma virus (Gazdar MSV) isolated from the HTG2 cell line was characterized. Electron microscopy of thin sections of the infected cells showed that the virus particles were assembled via the budding mechanism at the plasma membrane; the released virions possessed almost exclusively the enveloped type-A morphology characteristic of the immature form of retrovirus particles. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis of the virions under reducing conditions revealed a nonglycosylated protein of approx 65,000 daltons, p65. When analyzed under nonreducing conditions this band was resolved as well. Immunoprecipitation of p65 was accomplished with monospecific antisera against the individual "gag" gene-coded MuLV proteins p30, p15, and p12 but not with antisera against the MuLV envelope proteins, reverse transcriptase, or p10, indicating that the MSV p65 is related to but not identical with the Pr65(gag) of MuLV. The processed MuLV core proteins were not observed in purified HTG2 virions or in HTG2 cell extracts; thus proteolytic cleavage of the precursor is not required for the assembly or release of the MSV particles. Immunoprecipitation of lysed virions and HTG2 cell lysates with antisera to the MuLV envelope proteins gp70 and p15(E) demonstrated that detectable amounts of these and immunologically related components are not present in the virions

and are not expressed in the infected cells. It is suggested that the envelope proteins are not essential for the assembly and release of budding retrovirus particles. (16 refs)

- 79-6980 **Viral Specificity of H2-Restricted T Killer Cells Directed Against Syngeneic Tumors Induced by Gross, Friend, or Rauscher Leukemia Virus.** (Eng) Plata, F. (Dept. Genetics, Albert Einstein Coll. Medicine, Bronx, NY 10461); Lilly, F. *J Exp Med* 150(5): 1174-1186; 1979.

Cytolytic T lymphocytes (CTL) were generated against murine tumors induced by Gross, Friend, or Rauscher leukemia virus (LV) in syngeneic mixed leukocyte-tumor cell cultures. Tumor cells induced by Friend, Moloney, or Rauscher (FMR) virus and positive for the FMR antigen were killed by syngeneic CTL immune to any one of these three LV; the same CTL, however, could not kill syngeneic tumor cells induced by Gross LV. Gross-specific CTL were specific for syngeneic tumor cells expressing the Gross-virus-associated cell-surface antigen (GCSA) and not the FMR antigen. These patterns of CTL tumor specificity were true for mice of the H-2^b haplotype and of the H-2^d haplotype. Mice of the H-2^d haplotype consistently gave weak but specific CTL responses to syngeneic Gross LV-induced tumor cells. Attempts were made to map the H-2 restriction that accompanied the tumor specificity of the Gross LV-specific CTL. The results indicated that H-2^b CTL from BALB.B mice recognized Gross LV-induced tumor antigens in association with H-2 determinants coded by either H-2K^b or H-2D^b genes. However, H-2^d CTL from BALB/c mice were restricted to recognition of Gross LV-induced tumor antigens in association with H-2K^d; association with H-2D^d did not lead to significant killing by CTL. This pattern of specificity for H-2K and H-2D antigens is somewhat different from that seen in FMR-specific CTL. (29 refs)

- 79-6981 **Murine Leukemia Virus-associated Cell Surface Antigens in Rats Neonatally Infected With Gross Murine Leukemia Virus.** (Eng) Basch, R. S. (Dept. Pathology, New York Univ. Medical Center, 550 First Avenue, New York, NY 10016); Grausz, D.; Harris, N.; Mitchison, N. A. *J Natl Cancer Inst* 63(6): 1485-1492; 1979.

The appearance of cells positive for viral protein antigens (VPA) in the organs of newborn W/F, Lew, AS, and DA rats treated with Gross murine leukemia virus (MuLV) was studied. Most cells within the spleen and thymus and many cells within the bone marrow were positive for VPA 2 wk after MuLV treatment. Significant numbers of VPA-positive thymocytes were found in most animals by 3-4 wk. As the animals grew older, there was a modest increase in the number of VPA-positive cells in the spleen and thymus and a considerable increase in the intensity of fluorescent staining for VPA. Cells that were strongly positive for p30 antigen were found only among the leukemic thymocytes. Spleen cells with the strongest fluorescence had the properties of T cells, but VPA were also demonstrated on non-T-cells in both the spleen and bone marrow. VPA appeared to be actually synthesized by these cells and was not associated with the passive absorption of intact virus. The VPA-positive population expanded long before malignant cells could be detected in the rats and, in most animals, the entire T-cell compartment became VPA positive. These animals were unable to respond to MuLV antigens, and many eventually developed leukemia. However, some rats apparently broke the tolerance that followed neonatal infection and eliminated VPA positive cells from their tissues. (24 refs)

- 79-6982 **Physical Map of Biologically Active Harvey Sarcoma Virus Unintegrated Linear DNA.** (Eng) Goldfarb, M. P. (Center for Cancer Res., Massachusetts Inst. Technology, Cambridge, MA 02139); Weinberg, R. A. *J Virol* 32(1): 30-39; 1979.

BALB/c JLS V9 cells infected with Harvey sarcoma virus-murine leukemia virus (HSV-MuLV) complex contained unintegrated HSV linear DNA of 6.0-kilobase (kb) pair mass. The cells also contained two HSV closed circular DNA species along with MuLV-encoded linear and closed circular DNA species. HSV 6.0-kb pair linear DNA induced focal transformation upon transfection of NIH 3T3 mouse fibroblasts, and the biological activity of HSV DNA did not require helper MuLV functions. A physical map of restriction endonuclease cleavage sites along HSV 6.0-kb pair linear DNA was derived. Comparison of this map with one for Moloney MuLV DNA showed that the HSV and Moloney MuLV genomes are identical near their viral RNA 3' ends. (30 refs)

- 79-6983 **The Effect of Malignant Transformation on the Sensitivity of Murine Fibroblasts to the Antiviral Effect of Interferon.** (Eng) Morris, A. G. (Dept. Biological Sciences, Univ. Warwick, Coventry, CV4 7AL, England); Barrett, A. D.; Bird, R. M.; Burke, D. C. *FEMS Microbiol Lett* 6(3): 139-141; 1979.

Interferon (IF) was titrated in L cells and in a variety of transformed and untransformed murine fibroblast lines using a method involving inhibition of nucleic acid synthesis. The IF sensitivity of the cell line was expressed as the ratio of the IF titer in the cell line to the titer in L cells (3369). Normal NIH 3T3 cells were slightly less sensitive to IF than L cells, but all transformed clones derived from NIH 3T3 cells were at least 10-fold less sensitive than NIH 3T3. Similar results were obtained with normal mouse embryo fibroblasts and their transformed derivatives and with BALB/c 3T3 cells and transformed derivatives. Infection of NIH 3T3 cells by the Kirsten strain of murine leukemia virus (MLV) in the absence of transformation did not significantly change the sensitivity to IF. Incubation of IF overnight with cultures of NIH 3T3 cells and three of its MSV-transformed derivatives showed that IF is as stable in the presence of transformed cells as in the presence of untransformed cells. The data indicate that malignant transformation of murine fibroblasts reduces their intrinsic sensitivity to the antiviral effect of IF. It is suggested that the change of sensitivity is caused by an effect at some step early in the pathway of the action of IF, possibly at the level of the cell surface receptor for IF. (10 refs)

- 79-6984 **A Detailed Model of Reverse Transcription and Tests of Crucial Aspects.** (Eng) Gilboa, E. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA 02139); Mitra, S. W.; Goff, S.; Baltimore, D. *Cell* 18(1): 93-100; 1979.

A model of reverse transcription is described by which the detailed architecture of 10 molecular structures is predicted. The model includes a number of novel features for which experimental evidence is presented. Growing minus DNA strand is copied from the viral RNA only up to a position about 150 nucleotides from the 5' end of the RNA. Plus-strand DNA, after being copied from approx 600 nucleotides at the 5' end of the minus-strand DNA, then transcribes the first approx 20 nucleotides of the transfer RNA^{pr} primer (which is covalently attached to the 5' end of the minus DNA

strand). The 3' ends of the minus and plus DNA probably form a hybrid through the homology conferred by the primer binding site sequences. The minus and plus DNA strands are elongated in a continuous fashion resulting in a linear double-stranded DNA molecule containing a 600-nucleotide direct repeat at both ends. Thus, most of the features of the model have experimental support, and it appears to provide a credible description of reverse transcription. (29 refs)

- 79-6985 Viral Genome RNA Serves as Messenger Early in the Infectious Cycle of Murine Leukemia Virus. (Eng) Shurtz, R. (Dept. Life Sciences, Bar-Ilan Univ., Ramat-Gan, Israel); Dolev, S.; Aboud, M.; Salzberg, S. *J Virol* 31(3): 668-676; 1979.

When NIH/3T3 mouse fibroblasts were infected with the Moloney strain of murine leukemia virus, part of the genome RNA molecules were detected in the polyribosomes of the infected cells early in the infectious cycle. The binding appeared to be specific, since the release of viral RNA from polyribosomes was demonstrated with EDTA. When infection occurred in the presence of cycloheximide, most viral RNA molecules were detected in cytoplasm free of nuclei and polyribosomes. Size analysis on polyribosomal viral RNA molecules indicated that two size class molecules, 38S and 23S, were present in polyribosomes 3 hr after infection. Analysis of the polyribadenylate [poly(rA)] content of viral RNA extracted from infected polyribosomes demonstrated that such molecules bind with greatest abundance 3 hr after infection, as has been detected with total viral RNA. No molecules lacking poly(rA) stretches were detected in polyribosomes. Furthermore, when a similar analysis was performed on unbound molecules present in the free cytoplasm, identical results were obtained. It is concluded that no selection towards poly(rA)-containing viral molecules occurs on binding to polyribosomes. These findings suggest that the incoming viral genome of the Moloney strain of murine leukemia virus may serve as a messenger for the synthesis of one or more virus-specific proteins early after infection of mouse fibroblasts. (40 refs)

- 79-6986 Transcription of Endogenous C-Type Viruses in Resting and Proliferating Tissues of BALB/Mo Mice. (Eng) Jaenisch, R. (Heinrich Pette-Institut für Experimentelle Virologie und Immunologie, Universität Hamburg, Martinistrasse 52, 2000 Hamburg 20, W. Germany); Hoffmann, E. *Virology* 98(2): 289-297; 1979.

The effect of tissue proliferation on the genome expression of endogenous C-type viruses was studied. Liver cell proliferation was induced by partial hepatectomy in BALB/Mo mice. RNA sequences homologous to two classes of C-type viruses, to the Moloney leukemia virus (M-MuLV) endogenous in BALB/Mo mice, and to the xenotropic endogenous BALB 2 virus, were quantitated by molecular hybridization. RNA from resting liver tissue contained low concentrations of sequences homologous to either class of virus. No substantial increase in virus-specific RNA concentration was observed in regenerating livers between 18 hr and 5 days. The effects of liver cell proliferation on de novo infection with Moloney leukemia virus was studied. The number of M-MuLV-specific DNA copies in the livers of viremic BALB/c mice infected with virus as newborns did not change following partial hepatectomy. These results indicate that neither tissue-specific expression of M-MuLV in BALB/Mo mice nor organ-specific de novo infection with M-MuLV is dependent on the proliferative

state of the cells. This is consistent with the hypothesis that tissue-specific activation of the virus is dependent on regulatory mechanisms involved in cellular differentiation. (23 refs)

- 79-6987 Immunochemical Characterization of Tumor-associated Surface Antigens on a Moloney Leukemia Virus-Lymphoma, MBL-2. (Eng) Ng, A. K. (Lab. Immunodiagnosis, NCI, NIH, Bethesda, MD 20014); McIntire, K. R.; Suzuki, S.; Aoki, T.; Herberman, R. B. *Int J Cancer* 24(4): 504-512; 1979.

Tumor-associated surface antigens (TASA) on the Moloney leukemia virus (M-MuLV)-induced lymphoma MBL-2 in C57BL/6 mice (B6) were characterized. The surface proteins of MBL-2 cells were selectively radioiodinated and then extracted by Nonidet P40. The solubilized materials were reacted with a variety of antisera: monospecific antisera to murine leukemia viral proteins (anti-gp69/71, anti-p30, anti-p15, anti-p12, and anti-p10), sera from B6 which regressed murine sarcoma tumors induced by murine sarcoma virus (anti-MSV) and a rabbit anti-MBL-2 antiserum. The resulting radioimmune precipitates were analyzed and compared in sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDA-PAGE). Among all anti-viral protein antisera tested, only anti-gp69/71 was active, detecting a protein doublet of gp69/71 and its degradation fragments of 42,000 and 35,000 daltons. Radioimmune precipitates prepared with anti-MSV showed a SDS-PAGE pattern similar to that seen with anti-gp69/71. This result indicated that the surface antigen detected by the anti-MSV serum on MBL-2 tumor cell was probably a viral envelope antigen. The rabbit-anti-MBL-2 serum detected on the cell membrane an antigen of approx 95,000 daltons which was tumor-associated and did not appear to be related to virion components. The anti-MBL-2 serum still reacted with the 95,000 dalton antigen after absorption with disrupted M-MuLV virus and with gp69/71 and p30 purified from the virus. (46 refs)

- 79-6988 Effect of Anti-Mouse Type-I Interferon Globulin on the Evolution of Moloney Sarcoma Virus Induced Disease in Mice. (Eng) Ingnot, A. D. (Lab. Tumour Virology, Dept. Immunology, Inst. Immunology and Experimental Therapy, Polish Acad. Sciences, Wrocław, Poland); Ingnot, O.; Zoltowska, A.; Oleszak, E. *Int J Cancer* 24(4): 445-449; 1979.

The prolonged administration of potent sheep anti-mouse type-I interferon globulin (anti-IF IgG) had a marked potentiating effect on Moloney sarcoma virus (MSV) infection in mice. The extent of resistance to the MSV-induced disease was age-related. In 4-wk-old BALB/c mice, anti-IF IgG consistently induced 70%-80% mortality due to the progression of early or late tumors and erythroleukemia, whereas mortality of control mice was significantly lower. The same effect was obtained in 1-yr-old BALB/c mice. However, in 4-wk-old C57BL/6 or 6-wk-old BALB/c mice, anti-IF IgG enhanced only the growth of early tumors but had no effect on their regression. Antigenic stimulation with normal sheep globulin suppressed the growth of early tumors in suckling BALB/c or C57BL/6 mice and enhanced the evolution of late MSV-induced disease in older mice. (12 refs)

- 79-6989 The Integration Sites of Endogenous and Exogenous Moloney Murine Leukemia Virus. (Eng) van der Put-

ten, H. (Lab. Biochemistry, Univ. Nijmegen, Geert Grooteplein 21 Noord, Nijmegen, Netherlands); Terwindt, E.; Berns, A.; Jaenisch, R. *Cell* 18(1): 109-116; 1979.

Specific complementary DNA (cDNA) probes of Moloney and AKR murine leukemia viruses were prepared to characterize the proviral integration sites of these viruses in the genomes of Balb/Mo and Balb/c mice. The genetically transmitted Moloney provirus of Balb/Mo mice was detected in a characteristic Eco RI DNA fragment of 16×10^6 daltons. No fragment of this size was detected in tissue DNA from BALB/c mice infected as newborns with Moloney virus. The authors conclude that a viral integration site, occupied in preimplantation mouse embryos, is not necessarily occupied when virus infects cells in postnatal animals. Balb/Mo and Balb/c mice did carry the AKR structural gene in an Eco RI DNA fragment of 12×10^6 daltons. Further restriction analysis of this fragment indicated that both mouse lines carried one AKR-type provirus. Leukemogenesis in Balb/Mo and newborn infected Balb/c mice was accompanied by reintegration of Moloney viral sequences in new chromosomal sites of tumor tissues. Part of the reintegrated Moloney viral sequences were of subgenomic size. The AKR viral sequences, however, were not found in new sites. Further restriction analysis revealed that the development of Moloney virus-induced leukemia in BALB/Mo mice did not lead to detectable structural alteration of the genetically transmitted Moloney and AKR structural genes. (30 refs)

79-6990 Characterization of 40,000- and 25,000-Dalton Intermediate Precursors to Rauscher Murine Leukemia Virus *gag* Gene Products. (Eng) Naso, R. B. (Dept. Biology, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030); Karshin, W. L.; Wu, Y. H.; Arlinghaus, R. B. *J Virol* 32(1): 187-198; 1979.

Under steady-state labeling conditions, Rauscher murine leukemia virus-infected NIH Swiss mouse cells contain at least three major polyproteins [pPr65(gag), Pr40(gag), and pPr25(gag)] derived from the viral *gag* gene and having mol wts of 65,000, 40,000, and 25,000. pPr65(gag) has been shown previously to contain all four core proteins (p15, pp12, p30, and p10). Pr40(gag) was found to contain p30 and p10 antigenic determinants and peptide sequences. The rapidly labeled precursor proteins Pr40(gag) and pPr25(gag) were detectable early in pulse-chase experiments. Both precursors disappeared during the later stages of the chase period concurrent with the appearance of the mature viral core proteins. pPr65(gag) and pPr25(gag) were phosphorylated, pPr25 having a higher specific ^{32}P activity than pPr65. Nevertheless, peptide mapping studies, as well as the identification of the phosphorylated amino acid residues of pPr65, pPr25, and pp12, indicated that the same sites are phosphorylated regardless of whether the precursors or the mature pp12 are examined. (25 refs)

79-6991 Rauscher Leukemia Virus-induced Tumor Antigens: Complete Separation from gp70, p30 and H-2. (Eng) Alaba, O. (Lab. Cell Biology, NCI, Bethesda, MD 20205); Rogers, M. J.; Law, L. W. *Int J Cancer* 24(5): 608-615; 1979.

The possibility that the viral proteins gp70 and p30 and the histocompatibility antigen H-2 may function as the tumor-specific transplantation antigen (TSTA) of the Rauscher murine leukemia virus-induced leukemia RBL-5 and also in the secondary in vitro induction of cytotoxic T lymphocytes (CTL) was investigated. The antigen was obtained by plasma membrane isolation of RBL-5

cells and solubilization with sodium deoxycholate followed by gel filtration chromatography. A fraction containing excellent tumor-rejection activity but low amounts of gp70, p30, and H-2 was chromatographed on goat anti-gp70, goat anti-p30, and sheep anti-H-2(b) immunoaffinity columns. The data obtained indicate that neither gp70, p30, nor H-2 functions as the TSTA of RBL-5 leukemia, neither individually nor as a complex. Similarly, the antigen responsible for the specific secondary induction of CTL in vitro was shown to be distinct from these three proteins. (38 refs)

79-6992 Interactions Between Cellular Membrane Receptors and Oncovirus Envelope Glycoprotein: Influence of Enzymes and Protein-modifying Reagents on Receptors. (Eng) Bishayee, S. (Indian Inst. Experimental Medicine, Calcutta-700032, India); Strand, M. *Prog Clin Biol Res* 31: 721-731; 1979.

Binding of purified envelope glycoprotein (gp69/71) of Rauscher murine type C oncovirus to cellular membrane receptors was analyzed with reaction systems using intact cells or membranes of disrupted cells. The reaction was highly specific; only cells permissive of infection by Rauscher virus bound the ^{125}I -labeled viral glycoprotein. The specificity of binding was also demonstrated with respect to virus interference; cells productively infected with murine ecotropic type C virus failed to bind the virus envelope glycoprotein, whereas permissive cells infected with murine xenotropic virus continued to bind the Rauscher ecotropic virus glycoprotein. The reaction required the presence of Ca^{2+} or Mn^{2+} and was rapid and reversible. Studies of the enzymatic digestion of membranes suggested that the receptor is a protein which requires lipid either for its activity or for the integrity in the membrane. Receptor binding was greatly reduced by modification of histidine, tyrosine, and tryptophan residues. (26 refs)

79-6993 Identification of the Major Structural Proteins of Two BALB/c Myeloma C-Type Viruses. (Eng) Spriggs, D. R. (Div. Tumor Biology, Christ Hosp. Inst. Medical Res., 2141 Auburn Ave., Cincinnati, OH 45219); Krueger, R. G. *Virology* 98(1): 35-44; 1979.

The structural proteins of the C-type viruses produced by cloned lines of the MOPC-21 and FLOPC-1 BALB/c murine myelomas were studied. The viruses, designated MO₂₁-MuMAV and FL₁-MuMAV, respectively, were composed of proteins with mol wts of approx 99,000, 75,000, 17,000, 12,000, and 10,000 daltons. In addition, the viruses contained a "doublet" of a mol wt of approx 30,000 daltons. The 90,000- and 75,000-mol wt proteins were glycosylated. The p30 doublet and the original NB ecotropism were retained on subsequent virus cloning in SC-1 cells, passage through NIH-3T3 or BALB/3T3 cells, and microtiter plate cloning of SC-1 cells replicating cloned virus. Cloning the viruses in SC-1 cells resulted in potentiation of the ability of the viruses to replicate in these cells. The two cloned MuMAVs appeared to possess the p30 proteins previously described in endogenous BALB/c N- and B-tropic viruses. Tryptic peptide analysis of the myeloma virus p30 proteins demonstrated that the proteins shared extensive homology with, but not identity to, the two prototype BALB/c ecotropic endogenous viral p30 proteins. (25 refs)

79-6994 Apparent Posttranscriptional Block to Anaerobic Induction of Endogenous Leukemia Virus. (Eng) Whitaker-Dowling, P. A. (Dept. Microbiology, Univ. Pittsburgh

Sch. Medicine, Pittsburgh, PA 15261); Marotti, K. R.; Anderson, G. R. *J Virol* 32(1): 234-239; 1979.

Uninfected Fischer rat cells were induced by anaerobic stress to transcribe high levels of endogenous type C leukemia virus RNA. Complete 35S virus RNA with attached polyadenylic acid sequences was found associated with polysomes, indicating functional messenger RNA. The fact that no mature virus was released under these conditions indicates the presence of a posttranscriptional block to complete virus synthesis. (15 refs)

79-6995 Persistence and Expression of Herpes Virus in Guinea Pig B and T Spleen Cells. (Eng) Griffith, B. P. (Dept. Lab. Medicine, Yale Univ. Sch. Medicine, New Haven, CT 06516); Hsiung, G. D. *Proc Soc Exp Biol Med* 162(1): 202-206; 1979.

The role of spleen lymphocytes in acute and latent infection with guinea pig herpes-like virus (GPHLV) and the in vitro susceptibility of these lymphocytes to GPHLV were explored. Macrophage-, B-cell-, and T-cell-enriched populations obtained from infected guinea pigs were examined for infectious GPHLV. During acute infection, virus was first detected in the macrophage and B-cell fractions and was evident in the T-cell fraction only 5 days or more after infection. During latent infection, infectivity titers in the B fractions were consistently higher than in the T fractions. In both the B and T lymphocytes derived from latently infected guinea pigs, virus was expressed only after in vitro cultivation or cocultivation with susceptible cells. Lymphocytes infected in vitro did not support GPHLV replication, although latent infection of lymphocytes with GPHLV was readily accomplished in vivo. (21 refs)

79-6996 Conserved Polynucleotide Sequences Among the Genomes of Papillomaviruses. (Eng) Law, M. F. (Lab. Pathology, NCI, Bethesda, MD 20205); Lancaster, W. D.; Howley, P. M. *J Virol* 32(1): 199-207; 1979.

DNA from various papillomaviruses were analyzed for nucleotide sequence homology. Under standard hybridization conditions [melting temperature (T_m) -28 C], no homology was detectable among the genomes of human papillomavirus type 1 (HPV-1), bovine papillomavirus type 2 (BPV-2), or cottontail rabbit (Shope) papillomavirus (CRPV). However, under less stringent conditions (ie, T_m -43 C), stable hybrids were formed between radiolabeled DNAs of CRPV, BPV-1, or BPV-2 and the *Hind*III-*Hpa*I A, B, and C fragments of HPV-1. Under these same conditions, radiolabeled CRPV and HPV-1 DNAs formed stable hybrids with the *Hind*III B and C fragments of BPV-2 DNA. These results indicate that there are regions of homology with as much as 70% base match among all of these papillomavirus genomes. Furthermore, unlabeled HPV-1 DNA competitively inhibited the specific hybridization of radiolabeled CRPV DNA to BPV-2 DNA fragments, indicating that the homologous DNA segments are common among these remotely related papillomavirus genomes. These conserved sequences are specific for the *Papillomavirus* genus of papovaviruses, as evidenced by the lack of hybridization between HPV-1 DNA and either simian virus 40 or human papovavirus BK DNA under identical conditions. These results indicate a close evolutionary relationship among the papillomaviruses and further establish the papillomaviruses and polyoma viruses as distinct genera. (35 refs)

79-6997 Serological Relationship of Woodchuck Hepatitis Virus to Human Hepatitis B Virus. (Eng) Werner, B. G. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA 19111); Smolec, J. M.; Snyder, R.; Summers, J. *J Virol* 32(1): 314-322; 1979.

Two antigenic systems of the woodchuck hepatitis virus were identified. The relationship between viral antigens of the woodchuck hepatitis virus and the human hepatitis B virus was determined by using immunoprecipitation, hemagglutination, and immune electron microscopic techniques. Antigens found on the cores of the two viruses were cross-reactive. Lack of cross-reactivity between the surface antigens of the two viruses in immunodiffusion experiments suggested that the major antigenic determinants of the viral surfaces are different; however, results of passive hemagglutination tests indicated that there are common minor determinants. Nucleic acid homology, as measured by liquid hybridization, was found with 3-5% of the viral genomes. These results provide further evidence that woodchuck hepatitis virus is the second member of a new class of viruses represented by human hepatitis B virus. Since virus-infected woodchucks may acquire chronic hepatitis and hepatocellular carcinoma, these antigens and their respective antibodies will be useful markers for following the course of virus infection in investigations of the oncogenic potential of this class of viruses. The nucleocapsid antigen described may be a class-specific antigen of these viruses and thus may be useful in identifying members of the group. (17 refs)

79-6998 Physical Maps of Bovine Papillomavirus Type 1 and Type 2 Genomes. (Eng) Lancaster, W. D. (Dept. Surgery, Div. Otolaryngology, Case Western Reserve Univ., Cleveland, OH 44106). *J Virol* 32(2): 684-687; 1979.

Physical maps of bovine papillomavirus types 1 and 2 (BPV-1 and BPV-2) DNA were constructed from analysis of the electrophoretic mobilities of restriction endonuclease cleavage fragments from dual digests. BPV-1 DNA was sensitive to *Hind*III, *Hind*II, *Eco*RI, *Hpa*I, and *Bam*HI, with all but *Hind*III yielding single scissions. BPV-2 DNA was resistant to *Eco*RI; *Hind*III had one cleavage site, whereas *Hpa*I, *Bam*HI, and *Hind*II yielded multiple fragments. DNA from one of four BPV-1 isolates examined was resistant to *Hind*III, while another DNA isolate was resistant to *Bam*HI. The three BPV-2 isolates examined were uniformly sensitive to the restriction endonucleases employed. (11 refs)

79-6999 Enhancement of Feline Leukemia Virus-induced Leukemogenesis in Cats Exposed to Methylnitrosourea. (Eng) Schaller, J. P. (Dept. Veterinary Pathology, Ohio State Univ., Columbus, OH); Mathes, L. E.; Hoover, E. A.; Olsen, R. G. *Int J Cancer* 24(5): 700-705; 1979.

The effect of methylnitrosourea (MNU, 15-20 mg/kg, iv) on the susceptibility of young adult specific-pathogen-free cats to infection and induction of oncornavirus disease by the Rickard strain of leukemia virus (FeLV, inoculated ip or oronasally) was studied. Of eight cats injected with MNU plus FeLV, six developed persistent viremia, and five of the six became debilitated from thymic lymphomas. Only one of six non-MNU-treated cats of the same age became transiently viremic. Development of antibody to feline oncornavirus-associated cell membrane antigen was markedly depressed in the cats given MNU plus FeLV as compared with cats inoculated with FeLV alone. The data show that MNU was ap-

parently responsible for the obliteration of the age-related resistance in cats to FeLV infection and induction of FeLV-related disease; in nature, exposure to toxic chemical carcinogens may act as factors in determining susceptibility to feline oncornavirus in the cat. (33 refs)

- 79-7000 Susceptibility of Human Cell Lines to Feline Leukemia Virus and Feline Sarcoma Virus. (Eng) Azocar, J. (Dept. Microbiology, Harvard Sch. Public Health, 665 Huntington Ave., Boston, MA 02115); Essex, M. *J Natl Cancer Inst* 63(5): 1179-1184; 1979.

The susceptibility of human fibroblasts (WI-38) and various human lymphoid cell lines to feline-leukemia virus (FeLV) and feline-sarcoma virus (FeSV) was investigated. Human cells were highly sensitive to infection by FeLV subgroups B and C and by FeSV but resistant to infection by FeLV subgroup A. The cells became infected, produced infectious virus, and displayed no difference in morphology or viability. T-cell lines appeared to be more sensitive to FeLV and FeSV infection and to produce more virus than did autochthonous B-cells. B-cell lines with membrane IgG appeared more resistant to infection than did those with no membrane. (33 refs)

- 79-7001 Further Characterization of the Oncornavirus Inactivating Factor in Normal Mouse Serum. (Eng) Montelaro, R. C. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC 27710); Fischinger, P. J.; Larrick, S. B.; Dunlop, N. M.; Ihle, J. N.; Frank, H.; Schafer, W.; Bolognesi, D. P. *Virology* 98(1): 20-34; 1979.

The oncornavirus inactivating factor (OIF) contained in the normal sera of certain mouse strains was investigated. The OIF copurified quantitatively with the lipoprotein fraction of STU mouse serum subjected to flotation through sucrose density gradients. The buoyant material consisted of a heterogeneous population of spherical particles (200-1200 Å) that had a density of <1.006 g/ml, an apparent mol wt of $0.5-1 \times 10^7$, and contained triglyceride as the predominant (>70%) lipid moiety. In contrast to whole serum, which specifically inactivated xenotropic and polytropic murine oncornaviruses, the isolated low-density lipoprotein (VLDL) fraction was also able to inactivate murine ecotropic and feline leukemia viruses. Fractionation of STU lipoproteins or whole serum by extraction with ether:ethanol removed the OIF into the organic solvent. This factor extract inactivated the same spectrum of viruses as serum VLDL. However, sodium dodecyl sulfate-polyacrylamide gel electrophoretic analysis of unlabeled and radioiodinated factor extracts revealed no detectable protein components. NIH Swiss mouse sera harbored high titers of factor in an inactive form that displayed activity upon flotation or after extraction with ether:ethanol. This phenomenon was specific for this sera. No apparent significant reduction of OIF titer was observed in serial examinations of AKR mice during preleukemia or leukemia or in individual C57BL mice before and during the development of radiation-induced leukemia. (51 refs)

- 79-7002 Requirement of Human Chromosomes 19, 6 and Possibly 3 for Infection of Hamster x Human Hybrid Cells with Baboon M7 Type C Virus. (Eng) Brown, S. (Dept.

Biochemistry, Univ. Hosp. Medical Sch., Nottingham, England); Oie, H. K.; Gazdar, A. F.; Minna, J. D.; Francke, U. *Cell* 18(1): 135-143; 1979.

The replication pattern of the endogenous baboon type C virus M7 was studied in 29 primary Chinese hamster x human hybrid clones generated with leukemic cells from two patients with acute lymphoblastic and myeloblastic leukemia, respectively. There was no evidence of viral particulate RNA-dependent DNA polymerase (RDDP) or M7 antigen before viral infection. M7 virus replicated in human and some hybrid cells but not in Chinese hamster cells, indicating that M7 requires dominantly expressed human gene(s) for replication. Enzyme and cytogenetic analyses showed that a gene(s) coded for by human chromosome 19 is necessary for M7 infection of these hybrids. Detailed cytogenetic correlations revealed, however, that the chromosome 19+ /M7+ hybrid clones with intact chromosomes also had copies of chromosomes 3 and 6. Previously, *Bevi*, the putative integration site for M7 virus, was assigned to human chromosome 6. However, many clones with various combinations of chromosomes 3 and 6 lacked chromosome 19 and failed to replicate exogenously applied M7 virus, while tests of 27 secondary clones showed that M7 markers co-segregated with chromosome 19 markers. These findings all confirm the need for a chromosome 19-coded function in Chinese hamster x human hybrids. In addition, the yield of viral particulate RDDP produced into the culture fluid was 50- to 100-fold less per viral antigen-positive cell in the hybrids compared with human cells. Thus some form of regulation of viral components exists in the hybrid cells. When the virus replicating in hybrid cells was transferred back to human cells, this regulation was relaxed and the yield of RDDP per FA(+) cell greatly increased. It is concluded that human chromosomes 6 and 19 code for functions involved in M7 virus metabolism, and a function coded for by chromosome 3 cannot be excluded. (25 refs)

- 79-7003 Similarities in the Structural Organization of the Genomes of Stumptailed Macaque Virus (Strain HD) and Simian Virus 40. (Eng) Chowdhury, K. (Institut für Virusforschung, German Center Cancer Res., 6900 Heidelberg, W. Germany); Ammann, E.; Sauer, G. *J Gen Virol* 45(1): 223-226; 1979.

Previous studies showed that HD virus isolated from a tissue culture line of *Cercopithecus aethiops* origin has a genome consisting of a large size class with an extra fragment and a small class identical to the genome of stump-tailed macaque virus. Serological studies showed that HD virus-producing cells shared a common capsid antigen with all other members of the simian virus 40 (SV40)-polyoma subgroup of papovaviruses. To determine possible homologies between HD and SV40 viral genomes, HD virus DNA from a clonal line of Vero-76 cells that produce only the larger DNA class was digested with restriction endonucleases. The resulting five fragments A to E were hybridized with nick-translated ³²P-SV40 DNA and subjected to autoradiographic analysis. HD DNA fragments B, C, and D possessed homology to SV40 DNA, but the large fragment A and the small fragment E (missing in the small HD genome) lacked discernible homology. When the SV40 C fragment, which represents the origin of DNA replication was hybridized with HD DNA, homology was limited to the HD fragment C. Further experiments revealed homology between SV40 fragments coding for the VP1 capsid protein and HD fragment D. It is concluded that SV40 polynucleotide sequences that share homologies with the HD genome are confined to the late region and the origin of DNA replication. (16 refs)

79-7004 Syncytia Formation of Human Transformed Cell Lines by Simian Sarcoma Virus Type I (SSV-I/SSAV-I). (Eng) Ocho, M. (Dept. Biochemistry, Cancer Inst., Okayama Univ. Medical Sch., Okayama 700, Japan); Ogura, H.; Tanaka, T.; Oda, T. *Acta Med Okayama* 33(2): 137-140; 1979.

The induction of syncytia formation by simian sarcoma virus type I and simian sarcoma associated virus type I complex (SSV-I/SSAV-I) was investigated in human cultured cells originating from malignant tumors, virus-transformed cells, or normal embryonic cells. HeLa, HEP-2, and KB cells, which were derived from human malignant tumors, formed syncytia when cocultivated with SSV-I/SSAV-I-producing human embryonic lung (HEL) cells. KC cells (a human glioma cell line transformed by Rous sarcoma virus, RSV, and RSb cells (human embryonic cells transformed by simian virus 40 and RSV) also formed syncytia when cocultivated with SSV-I/SSAV-I-producing HEL; WI-38 (a diploid cell line), HEL, and HEC (two nontransformed human embryonic cell lines) did not form syncytia. These results indicate that SSV-I/SSAV-I forms syncytia in a variety of human transformed cells and does not always require the RSV genome for syncytia formation. (16 refs)

79-7005 Squirrel Monkey Retrovirus and *Herpesvirus saimiri*: Observation in the Same Cell Following Isolation. (Eng) Smith, G. C. (Microbiology and Infectious Diseases, Southwest Foundation Res. and Education, P.O. Box 28147, 8848 West Commerce St., San Antonio, TX 78284); Heberling, R. L.; Barker, S. T.; Kalter, S. S. *J Natl Cancer Inst* 63(4): 983-986; 1979.

The isolation of squirrel monkey retrovirus (SMRV) and *Herpesvirus saimiri* (HVS) in a mink lung cell culture previously inoculated with a squirrel monkey (*Saimiri sclerous*) throat swab suspension. HVS was identified by serum neutralization, and the retrovirus isolate was identified as SMRV by morphologic examination, microimmunodiffusion analysis, and demonstration of an Mg^{2+} preference for the RNA-directed DNA polymerase. 79-7006 Oligoribonucleotide Initiators for Herpes Simplex Virus DNA Synthesis In Vivo and In Vitro. (Eng) Muller, W. E. (Institut für Physiologische Chemie der Universität, Duesbergweg, 6500 Mainz, W. Germany); Zahn, R. K.; Arendes, J.; Falke, D. *Virology* 98(1): 200-210; 1979.

Experiments were carried out to determine the manner in which herpes simplex virus (HSV) DNA replication is initiated. Replicating HSV DNA, labeled with $[^3H]$ thymidine or $[^3H]$ uridine, was isolated from infected primary rabbit kidney cells. It was demonstrated that nascent DNA strands were covalently linked to oligoribonucleotide stretches. The chain length of this RNA segment was approx 36 nucleotides, which were located at the terminus of the replicating DNA. The extent of RNA initiator synthesis seemed to be closely correlated with the rate of HSV-DNA synthesis. The half-life of the RNA initiator was estimated to be 35 min. Evidence supporting the idea that cordycepin (3'-dAdo) is an inhibitor of RNA initiator synthesis included: (1) identical maximal chain length of the 3'-dAMP-RNA, (2) identical half-life of the 3'-dAMP-RNA segment, and (3) susceptibility to ribonucleases and alkali. The 3'-dAMP-RNA segment was not covalently linked to HSV-DNA. HSV-induced DNA polymerases

utilized not only deoxyribonucleotides $[d(pA)]_n$ but also ribonucleotides $[r(pA)]_n$ as initiators for the DNA template-dependent DNA polymerization. The initiating activity of both the DNA and the RNA segment was abolished when it carried a 3'-dAMP moiety at its 3'-terminus. (43 refs)

79-7007 Development of Tumours in Mice Chronically Infected with Herpes Simplex Virus. (Eng) Barinsky, I. F. (D. I. Ivanovsky Inst. Virology, USSR Acad. Medical Sciences, 123098 Moscow, USSR); Spynu, K. I.; Talalaeva, A. F.; Vanag, K. A. *Acta Virol (Praha)* 23(5): 367-374; 1979.

The oncogenicity of herpes simplex virus (HSV) in mice with chronic herpetic infections (induced by id inoculation followed by superinfection with HSV in normal or immunosuppressed animals) was studied. Within the first 10-14 days after inoculation, 20% of the mice infected with the L_2 strain of HSV type 1 and 25% of those infected with the 333 strain of HSV type 2 died of herpes infection. Neoplasms appeared 150-180 days after inoculation in 60% of the surviving mice infected with the L_2 strain and 20% of the surviving mice infected with the 333 strain. In the first group, 20/39 mice had round dense tumors in the area of the salivary glands; these mice also had tumors in the lungs and livers. The remaining 19 mice had tumors in the area of the cervical and axillary lymph nodes. Mice infected with strain 333 had similar tumors in the lymph nodes. Histologically, the tumors were adenocarcinomas and malignant lymphomas in L_2 -infected mice, and those in 333-infected mice were lymphomas and angio- or fibrosarcomas. No tumors were found at the site of HSV inoculation. HSV and Gross murine leukemia virus antigens were detected in the tumor cells, and HSV antigen was detected in cultures of tumor cells and in brain, spinal cord, liver, and spleen cells. HSV antibody was demonstrated in the sera of chronically infected tumor-bearing mice (titer = 32). (21 refs)

79-7008 Cervical Cancer Cell Lines Containing Herpesvirus Markers. (Eng) Melnick, J. L. (Dept. Virology and Epidemiology, Baylor Coll. Medicine, Houston, TX 77030); Adam, E.; Lewis, R.; Kaufman, R. H. *Intervirology* 12(2): 111-114; 1979.

Five epithelioid cell lines were established from invasive cervical carcinoma tissue and were examined for herpes simplex virus (HSV) antigens or virus-induced changes. Immunofluorescence studies with antiserum to an HSV type 2 nonstructural polypeptide revealed perinuclear antigens. In these cell lines, concentrations of a membrane fucoprotein that is regularly present in normal cells were reduced to levels similar to those previously observed in virus-transformed cells. One of the cell lines inoculated into athymic mice produced tumors. (17 refs)

79-7009 Proteins of Herpesvirus Type 2. V. Isolation and Immunologic Characterization of Two Viral Proteins in a Virus-specific Antigenic Fraction. (Eng) Smith, C. C. (Div. Comparative Medicine, Dept. Biochemistry and Biophysics, Johns Hopkins Medical Inst., 720 Rutland Ave., Baltimore, MD 21205); Aurelian, L. *Virology* 98(1): 255-260; 1979.

AG-e, a type-common herpes simplex virus (HSV) antigen, was isolated from soluble antigenic mixtures (SAM), and its immunogenic proteins were characterized. Immunoprecipitates

resulting from the reaction of extracts of HSV-2 (G)-infected HEP-2 cells, labeled with L -[35 S]methionine 4-16 hr after infection, with anti-crude AG-e sera and antiglobulin were dissociated and electrophoresed on 8.5% sodium dodecyl sulfate (SDS)-acrylamide gels. Two proteins with electrophoretic mobilities of ICP 12 and ICP 14 and comigrating with virion proteins VP5 and VP6, respectively, were resolved in the precipitates. In another experiment, agarose segments containing the precipitin band from the crossed immunoelectrophoresis (CIE) of HSV-2 (G) SAM and anti-crude AG-e sera were dissociated and electrophoresed with results similar to those of the first experiment. The immunologic reactivity of the antisera to pure AG-e, ICP 12, and ICP 14 was studied in four assays: CIE, immunodiffusion, indirect immunofluorescence, and antiglobulin-enhanced neutralization. The reactivity of all three antisera was virus-specific in these assays. The virus neutralizing potential of the anti-ICP 12 and ICP 14 sera and the observation that their reactivity is absorbed with HSV-2 (G) virions are consistent with the comigration of ICP 12 and ICP 14 with the two virion proteins, VP 5 and VP 6. The data indicate that ICP 12 and ICP 14 are radiochemically homogeneous on SDS-acrylamide gel electrophoresis and suggest that ICP 12 and ICP 14 are virus envelope proteins. (17 refs)

- 79-7010 Cytomegalovirus Infection of Ovarian Thecoma (Letter to Editor). (Eng) LiVolsi, V. A. (New Haven, CT); Merino, M. J. *Arch Pathol Lab Med* 103(12): 653-654; 1979.

The occurrence of cytomegalovirus involving an ovarian thecoma is reported. The patient, a 61-yr-old woman, developed angioimmunoblastic lymphadenopathy following an allergic response to quinidine, which was given for cardiac arrhythmias. Postmortem examination 18 mo later revealed a malignant lymphoma with features of immunoblastic B-cell sarcoma involving lymph nodes, lungs, and bone marrow. Invasive gastrointestinal candidiasis, cytomegalovirus pneumonia, and an encapsulated nodule resembling a fibrothecoma on the right ovary were also found. Ultrastructural examination of the nodule revealed viral capsids resembling those of the herpesvirus group. Several episodes of cutaneous herpesvirus infection had been documented in this patient, and it is possible that the pulmonary and ovarian manifestations of infection observed at autopsy represented reactivation of a latent viral infection. (6 refs)

- 79-7011 Effect of Diethylstilbestrol on Replication and Transformation by Human Herpesviruses. (Eng) Rapp, F. (Dept. Microbiology, Pennsylvania State Univ. Coll. Medicine, Hershey, PA 17033); Turner, N. *Intervirology* 12(2): 103-110; 1979.

Human embryo fibroblasts treated with diethylstilbestrol (DES) gave rise to slightly increased plaque production by cytomegalovirus (CMV); plaques were also slightly larger in treated cells as compared to those in untreated cultures. There was no significant enhancement of plaque production by herpes simplex virus (HSV) types 1 and 2 in the human cells or in primary rabbit kidney cells treated with DES. Growth analyses of HSV and CMV in DES-treated cells failed to reveal enhancement of virus production when compared to untreated cells. The frequency of biochemical transformation of mouse cells deficient in thymidine kinase (TK) to the TK⁺ phenotype by HSV was markedly enhanced when cells were pretreated with DES. TK⁺-transformed colonies arising from DES-treated cells were also larger than those derived from untreated cultures. These data reveal that DES increases

susceptibility of human cell lines to CMV infection and enhances efficiency of biochemical transformation of mouse cells by HSV. (43 refs)

- 79-7012 Cytomegalovirus Isolations from Cell Cultures of Human Adenocarcinomas of the Colon. (Eng) Hashiro, G. M. (Cell Culture Lab., Cancer Res. Center, Dept. Microbiology, Univ. Hawaii, Honolulu, HI 96822); Horikami, S.; Loh, P. C. *Intervirology* 12(2): 84-88; 1979.

Cytomegalovirus was isolated from cell cultures derived from 3 of 16 surgical specimens of colonic adenocarcinoma. The patients, a 34-yr-old male, a 76-yr-old female, and a 56-yr-old male, had metastatic lesions of the descending, sigmoid, and rectosigmoid colon, respectively. Cell cultures consisted of rapidly growing fibroblastic cells. Virus identification was accomplished through electron microscopic, cytochemical, and immunofluorescent procedures. Data did not indicate an etiologic association between virus infection and cancer; however, further studies of this association are indicated. (16 refs)

- 79-7013 Further Studies of Antibody Levels to *Herpes simplex* Virus, Cytomegalovirus, Measles Virus, and Adenovirus Type 5 in Burkitt's Lymphoma Patients. (Eng) Geser, A. (Unit Biological Carcinogenesis, International Agency Res. on Cancer, 150, cours Albert Thomas, 69372 Lyon, France); Feorino, P. M.; Sohler, R. *Med Microbiol Immunol (Berl)* 167(3): 175-180; 1979.

Sera collected from 14 Ugandan Burkitt's lymphoma (BL) patients before and after tumor manifestation and from 16 BL patients only after tumor diagnosis were tested for antibodies to herpes simplex virus (HSV), cytomegalovirus (CMV), measles virus, and adenovirus type 5 (Ad 5). Immunofluorescent techniques were used for all viruses except the measles virus, which was assayed using the complement fixation technique. For anti-HSV, anti-Ad 5, and anti-CMV activities, both the prevalence of positive antibody titers (≥ 10) and the geometric mean titer of the positives varied very little between BL cases and controls both before and after diagnosis; none of the differences were significant. The antibody response to measles virus appeared to be depressed in BL patients. Similar results were obtained in the 16 children for whom only one sera (post-tumor diagnosis) was available. These results conflict with a previously published report which found elevated antibody titers to Epstein-Barr virus (EBV) and also to CMV and varicella zoster virus in BL patients. The present results fail to confirm elevation of viral antibodies in BL patients other than those to EBV; the unique relationship between this virus and BL supports the notion of etiologic involvement. (7 refs)

- 79-7014 Deoxyribonuclease Activity Found in Epstein-Barr Virus Producing Lymphoblastoid Cells. (Eng) Clough, W. (Molecular Biology Div., Univ. Southern California, Los Angeles, CA 90007). *Biochemistry* 18(21): 4517-4521; 1979.

A deoxyribonuclease (DNase) activity that is not present in B cell lines that do not undergo Epstein-Barr virus (EBV) production or in virus-negative lymphocyte cell lines was detected in EBV-producer cell lines and characterized. The nuclease was purified 220-fold, with 20% recovery. It copurified through DEAE cellulose column chromatography with the EBV-induced DNA

polymerase in EBV producer cells but eluted as a separate peak of activity on phosphocellulose chromatography. The DNase activity had a sedimentation coefficient of 4.0S, a strong divalent cation requirement, an alkaline pH optimum, and the ability to use both native and denatured lymphocyte DNA as substrate, reducing both to monophosphonucleosides. The presence of this EBV-associated enzymatic activity in cells that are undergoing active EBV DNA replication suggests that it plays an important role in the viral DNA replicative process. (18 refs)

- 79-7015** Establishment of Anti-TNP Antibody-producing Human Lymphoid Lines by Preselection for Hapten Binding Followed by EBV Transformation. (Eng) Kozbor, D. (Dept. Tumour Biology, Karolinska Inst., S 104 01 Stockholm 60, Sweden); Steinitz, M.; Klein, G.; Koskimies, S.; Makela, O. *Scand J Immunol* 10(3): 187-194; 1979.

The establishment of human lymphoblastoid cell lines producing specific antibody against the hapten trinitrophenyl (TNP) was accomplished through selection of TNP-binding human B lymphocytes by TNP-rosetting and Ficoll-Isopaque separation, followed by Epstein-Barr virus (EBV) immortalization. Derived lines secreted polyclonal anti-TNP antibodies and contained relatively small numbers of specific rosette- and plaque-forming cells against TNP-RBC. Following rosetting with TNP-RBC, the frequency of rosette-forming cells increased from 2% to 75%. In parallel, the frequency of plaque-forming cells increased from 0.4% to 30%. The antibody titers in the supernatants increased from 64 to 512 and from 48 to 192, as measured by TNP agglutination and hemolytic assays, respectively. The antibodies were 19S, IgM. The specificity of the anti-TNP antibody was confirmed by the hapten inhibition test, in comparison and cross-reactivity tests with the supernatant of the previously established, EBV-transformed anti-4-hydroxy-3,5-dinitrophenacetic acid (NNP) antibody-producing cell line. Both antibodies were specific: the homologous hapten inhibited them but the heterologous hapten did not. (22 refs)

- 79-7016** Identification of Transcribed Regions of Epstein-Barr Virus DNA in Burkitt Lymphoma-derived Cells. (Eng) Rymo, L. (Dept. Clinical Chemistry, Univ. Gothenburg, Sahlgren's Hosp., S-413 45 Gothenburg, Sweden). *J Virol* 32(1): 8-18; 1979.

RNA extracted from the Burkitt lymphoma-derived cell line Raji and from Burkitt lymphoma tumor biopsies was labeled in vitro with ³²P and hybridized to electrophoretically separated restriction endonuclease fragments of Epstein-Barr virus DNA on nitrocellulose membranes. Only certain parts of the Epstein-Barr virus genome were represented as polyribosomal RNA in Raji cells, with a pronounced dominance of RNA sequences complementary to a 2.0 x 10⁶-dalton segment of Epstein-Barr virus DNA located close to the left end of the viral genome. Mapping of virus-specific polyribosomal RNA sequences indicated that a minimum of three regions of the Epstein-Barr virus genome are expressed in Raji cells. Total-cell RNA preparations from five Burkitt lymphoma biopsies contained RNA sequences homologous to the same regions of Epstein-Barr virus DNA as polyribosomal RNA from Raji cells, albeit at different relative proportions. (34 refs)

- 79-7017** Effect of 12-O-Tetradecanoyl-Phorbol-13-Acetate on the Replication of Epstein-Barr Virus. I.

Characterization of Viral DNA. (Eng) Lin, J. C. (Cancer Res. Center, Univ. North Carolina, Box 3, Swing Building 217H, Chapel Hill, NC 27514); Shaw, J. E.; Smith, M. C.; Pagano, J. S. *Virology* 99(1): 183-187; 1979.

The tumor promoter 12-O-tetradecanoyl-phorbol-13-acetate (TPA) induced replication of Epstein-Barr virus (EBV) DNA in the virus-producing human lymphoblastoid cell line P3HR-1 but not in nonproducer Raji cells. A sixfold increase in EBV genome copies per P3HR-1 cell paralleled the increase in percentage of cells synthesizing viral capsid antigen. In situ cytohybridization with EBV-specific complementary RNA showed that most of the TPA-treated population participates in the virus-producing cycle. In Raji cells, abortive induction occurred, with an increase in cells showing early antigen from <0.01% to approx 10%; but no increase was seen in EBV genome copies per cell. The optimal TPA concentration for induction of viral DNA replication was 10 nanograms/ml. EBV DNA synthesized in Raji cells superinfected by virus prepared from TPA-induced P3HR-1 cells increased approx 15-fold above that of Raji cells superinfected with control virus. The buoyant densities of EBV DNA isolated from virus from TPA-induced cells or of DNA from Raji cells superinfected with TPA-induced and control virus were identical; viral DNA from all sources had the same S value. The *Xho*I restriction endonuclease digestion patterns of TPA-induced viral DNA and control viral DNA were the same as the viral DNA recovered from Raji cells superinfected with TPA-induced and control virus. Some differences were noted in the molar ratios of some of the fragments. (15 refs)

- 79-7018** EBV-Specific Humoral Antibodies in Nasopharyngeal Carcinoma Patients in Cuba. (Eng) Ruiz, R. (Inst. Oncology and Radiobiology, MINSAP, Havana, Cuba); Gurtsevich, V.; Le Riverend, E. *Neoplasma* 26(2): 125-131; 1979.

Sera of 24 Cuban patients with nasopharyngeal carcinoma (NPC) and of 60 healthy donors were studied for IgG and IgA antibodies against antigens induced by Epstein-Barr virus (EBV). Forty-three healthy subjects and all 24 cancer patients showed IgG antibodies to EBV viral capsid antigen (VCA). However, high antibody titers ($\geq 1:160$) were observed more frequently among the patients (20/24) than among the healthy donors (9/60). All but one of the NPC patients had antibodies to EBV early antigen (EA), 21 had elevated titers ($\geq 1:40$). Antibodies to EA were present in 12 healthy persons, but none had elevated titers. Sera of healthy persons were negative for antibodies against the D component of EA, while the sera of 18 NPC patients were positive, and those of 14 showed elevated titers ($\geq 1:40$). Eighteen patients had IgA antibodies against VCA, 13 against EA complex, and 3 against the D component of EA. High antibody titers ($\geq 1:20$) were found against VCA and EA in 12 and 10 patients, respectively. All but two control sera were negative for IgA antibodies. The results demonstrate that NPC in Cuba is associated with EBV. NPC patients in Cuba have higher antibody titers to EBV-associated antigens than do Caucasian patients from countries where, as in Cuba, NPC is rarely found. (32 refs)

- 79-7019** The Study of Epstein-Barr Virus Induction by Cocultivation of EBV-Transformed Cells with a Mammary Carcinoma Cell Line MCF-1. (Eng) Nyormoi, O. (International Lab. Res. Animal Diseases, P.O. Box 30709, Nairobi, Kenya). *Eur J Cancer* 15(10): 1223-1229, 1231; 1979.

Cocultivation of a human mammary carcinoma cell line, MCF-7, with various Epstein-Barr virus (EBV)-transformed cell lines resulted in virus activation. Virus production was increased by increasing the ratio of MCF-7 cells to cells of the RO-bl line in cocultivation, but EBV induction was most easily detected when cells were mixed in a 1:1 ratio. The RO-bl cells were maximally induced by the second or third day, after which the induction level declined. Another transformed cell line, B95-8, was maximally induced as early as 24 hr, and the level of induction remained high throughout the next 3 days. Although some cell lines [B95-8, Daudi, Raji, and RO-bl (a derivative of Raji)] were readily inducible, other cell lines were not [P3HR-1, EHR-B-Ramos (EBR), and JY]. EBV producers appeared to produce only early antigen (EA) and not viral capsid antigen (VCA) upon cocultivation with MCF-7. In experiments combining autoradiography and immunofluorescence it was proved that only the EBV positive cells were inducible. Heterokaryon or hybrid formation was not involved. The MCF-7 cell line had no effect upon superinfection induction of EBV antigens by non-EBV producer cells, but increased the induction by iododeoxyuridine almost threefold. Induction of EBV by MCF-7 did not follow the pattern of spontaneous EBV production nor was it induced by MCF-7-conditioned medium, thus ruling out action by a soluble diffusible substance produced by MCF-7 cells. - 79-7020 Properties of Viruses Isolated from a Culture of Human Fibroblasts Treated with a Paraganglioma Filtrate. (Rus) Klenova, A. V. (N. F. Gamaleia Inst. Epidemiology and Microbiology, Moscow, USSR); Borodina, N. P.; Chizhevskaya, V. I.; Eremina, L. A.; Voskoboinik, A. D.; Shevliagin, V. Ia. *Vopr Onkol* 25(9): 42-46; 1979.

An attempt was made to characterize viruses isolated from human fibroblast cultures treated with an acellular filtrate of malignant human paraganglioma. Centrifugal analysis of purified virus preparations from transformed fibroblast cultures revealed the presence of a DNA-containing virus with buoyant density of 1.24-1.28 g/ml and an RNA-containing virus with buoyant density of 1.16-1.18 g/ml. The RNA-containing virus had no hemagglutinating activity and did not induce tumors in newborn Syrian hamsters; the DNA-containing virus, which had the properties of a papova virus, was tumorigenic in the hamsters and caused destructive changes in rat and murine embryo cultures and monkey kidney cell cultures. (10 refs)

- 79-7021 Construction and Analysis of Viable Deletion Mutants of Polyoma Virus. (Eng) Magnusson, G. (Dept. Biochemistry, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Berg, P. *J Virol* 32(2): 523-529; 1979.

Viable polyoma virus mutants with small deletions ranging in size from 2-75 base pairs were obtained by infecting 3T3 cells with polyoma DNA that had been cleaved once with *Hae*II endonuclease or with DNase-Mn²⁺ digestion. The *Hae*II endonuclease-cleaved DNA yielded mutants with deletions at map position 72-73, while the mutants generated by DNase I-Mn²⁺ digestion had deletions either at map position 72-73 or within the map coordinates 92 and 99. Both groups of mutants appeared to grow as well as wild-type virus in 3T3 cells. The deletions at map position 72-73 did not alter transforming ability of the virus in rat cells; thus, the region just to the early side of the origin of DNA replication does not appear essential for vegetative growth or transformation. However, mutants with deletions in the region

between map coordinates 92 and 99, a segment thought to code for polyoma large and middle T antigens, transformed rat cells at only 0.2 to 0.05 the efficiency of wild-type virus. (36 refs)

- 79-7022 Secondary Structures in Polyoma DNA. (Eng) Wu, M. (Dept. Chemistry, California Inst. Technology, Pasadena, CA 91125); Manor, H.; Davidson, N. *J Virol* 32(1): 334-338; 1979.

The following three reproducible secondary-structure features were observed on single strands of polyoma virus DNA mounted for electron microscopy by the T4 gene 32 protein technique: a hairpin fold-back extending from 92.9 ± 0.8 to 95.0 ± 0.7 map units, a small loop extending from 63.2 ± 3.1 to 68.5 ± 2.8 map units, and a big loop extending from 51.9 ± 2.3 to 68.9 ± 2.1 map units. Both loops were bounded by inverted repeat stems of length 40 ± 20 base pairs. The stem sequences around 68.5 and 68.9 of the large and small loops overlapped either partially or completely. The inverted repeat stems of the two secondary-structure loops appeared to lie in the regions of polyoma virus DNA flanking and probably very close to the sequences that are spliced out in the formation of the late 16S and 18S messages, whereas the hairpin fold-back appeared to map at a splicing point of an early message. These structures may therefore be important for the processing of the primary transcripts to form the early and late messages. (6 refs)

- 79-7023 Deletion Mutants of Polyoma Virus Defining a Nonessential Region Between the Origin of Replication and the Initiation Codon for Early Proteins. (Eng) Bendig, M. (Dept. Biological Chemistry, Univ. Michigan, Ann Arbor, MI 48109); Folk, W. R. *J Virol* 32(2): 530-535; 1979.

Polyoma virus mutants with deletions as large as 90 base pairs were isolated by selecting spontaneously arising genomes resistant to endonuclease *Hae*II or by treating *Hae*II- or *Bgl*-cleaved linear DNA's with S1 nuclease and exonuclease III. All of the mutants were viable, indicating that a nonessential region in the polyoma genome exists between the origin of DNA replication and the initiation codon for translation of early proteins. Several mutants with large deletions had altered growth properties, with smaller plaques and lower virus yields than the parental wild-type virus. These viruses may lack sites that are important for DNA replication or for transcription and translation of early messenger RNA's. All of the mutants tested were able to transform BHK-21 cells to anchorage independence. (38 refs)

- 79-7024 Polyoma Virus. The Early Region and Its T-Antigens. (Eng) Soeda, E. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London, England); Arrand, J. R.; Griffin, B. E. *Nucleic Acids Res* 7(4): 839-857; 1979.

Characterization of the DNA sequence of the early coding region of polyoma virus showed it to consist of 2,739 nucleotides. The sequence predicts that more than one reading frame can be used to code for the three known polyoma virus early proteins (designated small, middle, and large T-antigens). From the DNA sequence, the 'splicing' signals used in the processing of viral RNA to functional messenger RNAs can be predicted along with the sizes and sequences of the three proteins. Other unusual aspects of the DNA sequence were noted, including the presence of the sequence

AATAAA twice within the early region (both the signal and termination codons on both DNA strands). The DNA sequences and the predicted amino acid sequences of the respective large T-antigens of polyoma virus and the related simian virus 40 were compared, and both notable sequence similarities and differences within the early regions of these viruses were found. (36 refs)

- 79-7025 Differential Adsorption of Polyoma Virions and Capsids to Mouse Kidney Cells and Guinea Pig Erythrocytes. (Eng) Bolen, J. B. (Section Virology and Oncology, Div. Biology, Kansas State Univ., Manhattan, KS 66506); Consigli, R. A. *J Virol* 32(2): 679-683; 1979.

Surface adsorption of ^{125}I -labeled polyoma virions and capsids was examined in mouse kidney cells (MKC) and guinea pig erythrocytes (GP-RBC). Purified polyoma capsids, while lacking the ability to compete with polyoma virions for specific binding sites on the surface of MKC, were nevertheless able to block virion adsorption to GP-RBC. UV-inactivated virions blocked cellular receptors on MKC and thus inhibited virion infection of the cells. Capsids were unable to inhibit virion infection of MKC. Adsorption of polyoma virions to MKC and infection of these cells were independent of the ability of the virions to agglutinate GP-RBC. (17 refs)

- 79-7026 Isolation and Characterization of Polyoma Virus Genomes with Deletion Between the Origin of Viral DNA Replication and the Site of Initiation of Translation in the Early Region. (Eng) Wells, R. D. (Dept. Biochemistry, Univ. Wisconsin, Madison, WI 53706); Hutchinson, M. A.; Eckhart, W. *J Virol* 32(2): 517-522; 1979.

Nineteen polyoma virus mutants were isolated after treatment of isolated viral DNA with *Hae*III and S1 nuclease and infection of 3T6 cultures in a plaque assay. Electrophoresis analysis of the *Hpa*III digestion fragments indicated that all the mutants contained deletions in *Hpa*III fragment 5, that all mutants except 51-6 lacked a *Hha*I cleavage site in the neighborhood of the *Hae*III site. Analysis of the *Hae*III digestion fragments indicated that mutants 51-2 and 51-6 had patterns indistinguishable from wild-type, and that mutants 51-8, 51-15, and 51-20 had deletions that included the *Hae*III cleavage site. All 19 mutants appeared to be competent for lytic growth and for transformation of rat F2408 cells. (26 refs)

- 79-7027 Electron Microscopic Mapping of RNA Transcribed from the Late Region of Polyoma Virus DNA. (Eng) Manor, H. (Dept. Biology, Technion-Israel Inst. Technology, Haifa, Israel); Wu, M.; Baran, N.; Davidson, N. *J Virol* 32(1): 293-303; 1979.

The polyoma virus (Py) RNA species transcribed from the L DNA strand of the 'late' region of the Py genome in Py-infected mouse cells were mapped by hybridization with specific fragments of Py DNA followed by electron microscopic visualization of the hybrids. Total cellular polyadenylated Py-specific RNA molecules having an S value in the range of 16S to 20S were purified by oligodeoxythymidylic acid-cellulose column chromatography, preparative hybridization with Py DNA, and sucrose gradient centrifugation. Cytoplasmic Py-specific RNA was purified similarly but without fractionation by sucrose gradient centrifugation.

Hybrids of these RNA molecules and Py DNA fragments were spread for electron microscopy by either the cytochrome c technique or the bacteriophage T4 gene 32 protein method. The polyadenylic acid at the 3'-end of the RNA in the hybrids was identified by labeling with simian virus 40 DNA circles to which polybromodeoxyuridylic acid tails had been covalently attached. These experiments revealed the presence of three L DNA strand transcripts in both RNA preparations. Two of these RNA molecules were found to be spliced from chains transcribed from two noncontiguous parts of the late region. The third molecule either was a continuous transcript of the entire late region or contained a splicing feature which was too small to be reliably observed. The 5'-ends of the three RNA species mapped within a region extending from 68 to 70 map units on the Py restriction endonuclease map. Each of the two spliced molecules contained a 5'-terminal leader sequence transcribed from a DNA segment with an estimated length of 60 to 110 nucleotides. The 3'-ends of the leaders mapped at 66.7 ± 1.0 and 66.4 ± 0.50 map units. In these molecules the 5'-ends of the other part (the main body) mapped at 59.4 ± 0.90 and 49.4 ± 2.0 map units, respectively. The 3'-termini of all three RNA species mapped at 24 to 25 map units. (32 refs)

- 79-7028 Further Investigations on the Antioncogenic Activity of A/PR8/34 (HON1)-Influenza Virus on Polyoma Virus Induced Tumors in Newborn Wistar Rats. (Eng) Desselberger, U. (Inst. Virology, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany); Drescher, J.; Georgii, A.; Ostertag, H. *Zentralbl Bakteriell [Orig A]* 240(4): 411-423; 1978.

The anti-oncogenic activity of influenza virus was investigated in newborn Wistar rats inoculated simultaneously with polyoma virus (Stewart Eddy strain). The rats were inoculated ip with egg-adapted A/PR8/34 (HON1) influenza virus and sc with the polyoma virus within 24 hr after birth. The kidneys were examined for tumors 40 days later. The anti-oncogenic activity of influenza virus was neutralized by the addition of homologous influenza antibodies, indicating that this activity was caused by the virus rather than by any nonviral material. Anti-oncogenic activity was critically dependent on the relative doses of both viruses (576-2,591 hemagglutinating units of polyoma virus; 106-848 hemagglutinating units of influenza virus) and declined with storage at 4°C. Influenza virus significantly reduced antibody responses to polyoma virus in all experiments, suggesting that influenza virus reduced the multiplication of polyoma virus. Conversely, polyoma virus significantly enhanced antibody responses to influenza virus in two of six experiments. The anti-oncogenic activity of influenza virus seemed to be a result of its hemagglutinin component rather than the presence of neuraminidase. Influenza virus markedly reduced polyoma virus adsorption on rat embryo fibroblast cultures, suggesting that anti-oncogenic activity may be at least partially caused by interference with polyoma virus adsorption on target cells. (12 refs)

- 79-7029 Polyoma Virus-specific 55K Protein Isolated from Plasma Membrane of Productively Infected Cells is Virus-coded and Important for Cell Transformation. (Eng) Ito, Y. (Imperial Cancer Res. Fund Lab., Lincoln's Inn Fields, London, WC2A 3PX, England). *Virology* 98(1): 261-266; 1979.

A 55,000 (55K_{PM}) mol wt protein obtained from the plasma membrane fraction of mouse cells productively infected with polyoma virus was compared with polyoma virus middle (55K mol wt) T an-

tigen. The electrophoretic mobility of 55K_{PM} from the plasma membrane fraction was indistinguishable from that of the middle T antigen from a detergent extract of unfractionated productively infected cells. Cells infected with the nontransforming polyoma virus mutant NG-18 did not express plasma membrane-associated 55K_{PM} protein or middle T antigen, which suggests that the middle T antigen and the 55K_{PM} protein are identical. More direct evidence on the identity of the proteins was obtained by peptide mapping of (35S) methionine-labeled middle T antigen and 55K_{PM}. The methionine peptides were analyzed by a two-dimensional fingerprinting technique, which showed that the fingerprint of the 55K_{PM} was similar (and probably identical) to that of middle T antigen. These results establish that the middle T antigen is associated with cell membranes. Of three membrane fractions separated so far, the 55K_{PM} protein is enriched in the plasma membrane fraction. These results suggest that the plasma membrane may be a site where at least one of the primary events of in vitro cell transformation by the virus occurs. (18 refs)

- 79-7030 Two Cases of Epidermodysplasia Verruciformis with Malignant Changes. (Jpn) Miyachi, Y. (Dept. Dermatology, Faculty Medicine, Kyoto Univ., Kyoto, Japan); Oguchi, M.; Ogino, A.; Komura, J.; Uehara, M.; Nikaido, M. *Hifuka Kiyo* 74(1/2): 29-35; 1979.

The cases of a 27-yr-old man and a 24-yr-old man with epidermodysplasia verruciformis that underwent malignant changes are reported. The parents of both patients were cousins, but neither family had histories of the same diseases. The first patient had human leukocyte antigens A9, --B12, and BW54 and the second patient had A2, A9, BW52--. Histological examination of the first patient's tumor showed translucent cells with a granulocytic layer, a brush-border cell layer, and small round cell infiltration of the papillary epithelial layer. The second patient had squamous cell carcinoma cells with mitotic patterns. Both tumors were resected surgically. Because some cellular immunity tests were depressed, it was thought that hereditary or immunological defects may have accounted for the absence of the spontaneous regression phenomenon seen in plane warts. (21 refs)

- 79-7031 BK Virus DNA: Complete Nucleotide Sequence of a Human Tumor Virus. (Eng) Yang, R. C. (Section Biochemistry, Molecular and Cell Biology, Cornell Univ., Ithaca, NY 14853); Wu, R. *Science* 206(4417): 456-462; 1979.

The complete DNA sequence of the human papovavirus BK is presented. From the 4963 base-pair sequence of BK virus (MM strain), the amino acid sequence of at least five proteins can be deduced: a T antigen and a t antigen, which share amino terminal peptides; proteins VP2 and VP3, which share 232 amino acids; and protein VP1, whose coding sequence overlaps those for VP2 and VP3 by 113 nucleotides but is read in a different frame. The gene loci and the arrangement of genes are strikingly similar in BK virus and simian virus 40 (SV40). The sequence of the deduced proteins in BK virus shares 73% amino acid homology with those in SV40, while the DNA sequence of the two viruses shares 70% homology, suggesting a close evolutionary relationship. However, the repeated DNA sequences in the noncoding regions of these viruses are different. (39 refs)

- 79-7032 Helper Function for Adenovirus Replication in Monkey Cells by BK Human Papovavirus. (Eng) Miyamura, T. (Natl. Inst. Allergy and Infectious Diseases, NIH,

Bethesda, MD 20205); Takemoto, K. K. *Virology* 98(1): 279-282; 1979.

Experiments were carried out to study the growth of BK human papovavirus (BKV) in CV-1 monkey kidney cells at the permissive temperature (40 C) and at 37 C. At 37 C, all infected cells synthesized T antigen, but <5% of the cells produced viral antigen. When infected cells were incubated at 40 C, characteristic cytopathic effects (CPE) were observed with high virus yields. The inhibition of BKV growth in CV-1 cells was thus shown to be a temperature-dependent phenomenon. Experiments were then conducted to determine whether BKV provides a helper function for adenovirus >growth in CV-1 cells at temperatures that were either permissive (40 C) or semipermissive (37 C) for BKV replication. At 37 C, there was a low level of adenovirus enhancement of 0.5 to 1.0 log increase. However, at 40 C, there was a 1.5 to 2.5 log increase in adenovirus yields, comparable to those obtained by coinfection with simian virus 40 (SV40) and adenovirus. These data provide additional information on common viral functions shared by BKV and SV40. (27 refs)

- 79-7033 Perinatal Induction of Medulloblastomas in Syrian Golden Hamsters by a Human Polyoma Virus (JC). (Eng) Zu Rhein, G. M. (Dept. Pathology, Univ. Wisconsin Medical Center, Madison, WI 53706); Varakis, J. N. *Natl Cancer Inst Monogr* (51): 205-208; 1979.

Outbred Syrian hamsters (*Mesocricetus auratus*) developed one or more malignant medulloblastomas 3-6 mo after they were inoculated as newborns intracerebrally and sc with JC virus, a papovavirus originally isolated from a human with progressive multifocal leukoencephalopathy. About 95% of the tumor-bearing animals had at least one neoplasm of the cerebellum that corresponded in location and morphology to the human medulloblastoma of childhood. Hamster tumors were located either in the vermis or in one hemisphere, and were about 5 mm wide. The tumors originated from cells of the internal granular layer (IGL) of the cerebellum. The first atypical IGL cell appeared from 4-8 wk after inoculation, and incipient tumors were visible at 10 wk. Virus was isolated from five of seven hamster medulloblastomas. The JC virus was the first infectious agent to produce this neoplasm in any species. It is hypothesized that upon injection, the virus spreads over the brain surface, infecting the mitotically active cells still on the surface in the external granular layer. The viral genome incorporates into the cellular genome, and the cells transform. Later, the transformed cells migrate to the IGL, and, under the influence of unknown factors, the transformation is subsequently expressed phenotypically. (8 refs)

- 79-7034 Characterization of Different Tumor Antigens Present in Cells Transformed by Simian Virus 40. (Eng) Smith, A. E. (Translation Lab., Imperial Cancer Res. Fund, London WC2A 3PX, England); Smith, R.; Paucha, E. *Cell* 18(2): 335-346; 1979.

Different forms of tumor antigen (T-ag) present in a number of simian virus 40 (SV40)-transformed cell lines were analyzed by tryptic peptide fingerprinting and by cell-free synthesis. Fingerprint analysis showed that nonviral tumor antigens (NVT-Ags) had few if any peptides in common with large T antigens or small t antigens, and that they lacked the amino terminal tryptic peptide and the peptides unique to small t. NVT-Ags from different species had different fingerprints, but those isolated from different

transformants of the same cell line were identical. The size of NVT was unaltered in cells transformed by mutants of SV40 with deletions in the region 0.60-0.55 map units. The messenger RNA for NVT did not hybridize to SV40 DNA. The other forms of T-Ag isolated from transformed cells fell into three classes: shortened forms of large T (truncated large T); multiple species of T-Ag with mol wt very similar to, but distinct from, those of normal large T (large T doublets and triplets); and elongated forms of large T (super T). These proteins all contained the normal amino terminus of SV40 T-Ags, and the truncated forms of large T lacked peptides from the carboxy terminal half of large T. One species of super T (mol wt 130,000) contained only those methionine tryptic peptides present in normal large T, although it may contain some peptides in more than one copy. (46 refs)

- 79-7035 Subculture Requirement for Rescue of SV40 from 'Nonrescuable' Cell Lines. (Eng) Moyer, M. P. (Thor- man Cancer Res. Lab., Trinity Univ., San Antonio, TX 78284); Moyer, R. C. *Intervirology* 12(2): 89-95; 1979.

A variety of cell lines that had not previously yielded virus after fusion with permissive cells were used in experiments to determine whether simian virus 40 (SV40) could be rescued following extensive subculture and assessment of virus rescue. After cell fusion with permissive TC7 cells, SV40 could be rescued from the H50, BRKSV (Bam 1 linear), 14B, and 14B (1-4) cell lines, all of which contain the entire SV40 genome. Virus could not be rescued from the T22 cell line, which was transformed by defective virus. The T-antigen-negative flat revertant cell line 14B (1-4) converted to T-antigen-positive prior to virus rescue. Subculture and extensive monitoring for production of infectious virus appeared to be prerequisites for the detection of virus rescue. These studies suggest that previously reported negative results for rescue of other viruses, such as polyoma and adenovirus, should be reevaluated. (14 refs)

- 79-7036 Oncogenicity of Simian Virus 40 Deletion Mutants that Induce Altered 17-Kilodalton t-Proteins. (Eng) Lewis, A. M. (Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD 20205); Martin, R. G. *Proc Natl Acad Sci USA* 76(9): 4299-4302; 1979.

Plaque-purified viable simian virus 40 (SV40) deletion mutants containing deletions between map positions 0.54 and 0.59 induced tumors in 21-92% of LSH hamsters inoculated during the first 24 hr of life. *HinfI* restriction endonuclease digestion patterns of the genomes of virions rescued from the tumor cells and the distribution of SV40 early proteins in these cells indicated the association of tumor induction with the inoculated mutants. These results imply that the DNA sequences comprising that portion of the early SV40 genome between map positions 0.54 and 0.59 are not essential for SV40 oncogenicity. (20 refs)

- 79-7037 Isolation of a SV40-like Papovavirus From a Human Glioblastoma. (Eng) Scherneck, S. (Central Inst. Molecular Biology, 1115 Berlin-Buch, W. Germany); Rudolph, M.; Geissler, E.; Vogel, F.; Lubbe, L.; Wahlte, H.; Nisch, G.; Weickmann, F.; Zimmermann, W. *Int J Cancer* 24(5): 523-531; 1979.

Indirect immunofluorescence staining of a human glioblastoma multiforme (M27) tested in early cell cultures showed Simian virus 40 (SV40)-related tumor (T)-antigen in 95% of the cells. SV40-related viral capsid (V)-antigen was absent in all cells tested. Virus rescue was performed by fusing M27 cells with SV40-permissive CV-1 monkey cells by using polyethylene glycol as fusion factor. Virus particles were isolated from the glioblastoma multiforme and termed SV40-GBM. Electron microscopy showed that the SV40-GBM particles correspond in size and morphology to papovaviruses. Serological tests (hemagglutination, neutralization, fluorescent antibody) revealed that the virus is indistinguishable from SV40; nevertheless, SV40-GBM did appear to differ slightly from the SV40 wild type. SV40-GBM could propagate and produce a cytopathic effect in both CV-1 cells and primary fetal human kidney cells. Digestion of SV40-GBM DNA with the *HindIII* restriction endonucleases revealed minor differences compared with SV40 DNA. (36 refs)

- 79-7038 The SV40 A Gene Product is Required for the Production of a 54,000 MW Cellular Tumor Antigen. (Eng) Linzer, D. I. (Dept. Biochemical Sciences, Princeton Univ., Princeton, NJ 08540); Maltzman, W.; Levine, A. J. *Virology* 98(2): 308-318; 1979.

Experiments were carried out to determine whether a 54,000 mol wt protein that is specifically immunoprecipitated from simian virus 40 (SV40)-infected and -transformed mouse cells is also present in uninfected Balb/c 3T3 cells and to further characterize the protein. It was demonstrated that low levels of a 54,000 mol wt protein are present in uninfected, nontransformed mouse 3T3 cells. Following infection or transformation of 3T3 cells with SV40, the levels of this protein increased 25- to 50-fold. In SV40-infected 3T3 cells, the rate of synthesis of the viral 94,000 mol wt T antigen increased over the first 14 hr after infection and then declined. In contrast, the rate of synthesis and/or the stability of the 54,000 mol wt protein increased over a 22-hr period and then remained at max levels for an additional 30 hr. Temperature-sensitive A gene mutants of the SV40 large T antigen, at the nonpermissive temperature, failed to initiate or maintain the max increased levels of 54,000 mol wt protein observed in virus-infected or -transformed cells. SV40 deletion mutants in the small t antigen unique region of the genome stimulated the production of wild-type levels of the protein in virus-infected cells. The results demonstrate that the SV40 A gene product is required to initiate and possibly maintain the high levels of the 54,000 mol wt protein found in virus-infected and -transformed cells. (19 refs)

- 79-7039 Detection of Simian Virus 40 Related T-Antigen in Human Meningiomas. (Eng) Scherneck, S. (Abteilung Zellgenetik, Zentralinstitut für Molekularbiologie, Akademie der Wissenschaften der DDR, Lindenberger Weg 70, DDR-115 Berlin-Buch, E. Germany); Lubbe, L.; Geissler, E.; Nisch, G.; Rudolph, M.; Wahlte, H.; Weickmann, F.; Zimmermann, W. *Zentralbl Neurochir* 40(2): 121-127, 129-130; 1979.

Indirect immunofluorescence testing of 37 human primary meningiomas in cell culture revealed the 12 expressed simian virus 40 (SV40)-related-tumor (T)-antigen. In at least one case, treatment of the patients with SV40-containing polio vaccine was excluded. The percentage of T-antigen-positive nuclei varied between 20% and 95%. There was a decrease in T-antigen-positive cells in the same tumor culture with increasing passage. The T-antigen was granular and filled the whole nucleus. None of the meningioma

cell cultures tested showed SV40-related V-antigen, nor could infectious virus be visualized by electron microscopy. The presence of SV40 T-antigen could not be correlated with the sex or age of the patients, nor with the histological or chromosomal characteristics of the meningioma. These findings indicate that early functions of a papovavirus-like particle are expressed in the meningiomas: this particle shares at least some of the antigenic properties of SV40. (23 refs)

- 79-7040** Comparison of Simian Virus 40-induced Mouse and Hamster Tumor-specific Transplantation Antigens. (Eng) Coggin, J. H. (Dept. Microbiology and Immunology, Coll. Medicine, Univ. South Alabama, Mobile, AL 36688). *J Natl Cancer Inst* 63(4): 1029-1034; 1979.

The tumor-specific transplantation antigens (TSTA) of mouse and hamster tumor cells induced in vivo by simian virus 40 (SV40) were compared. TSTA extracted from SV40-induced mouse sarcoma cells and from intact irradiated mouse sarcoma cells did not prevent SV40 oncogenesis or tumor take following transplantation in LVG strain Syrian hamsters, but they did prevent tumor take following specific tumor transplantation in BALB/c mice. Human and hamster cells transformed by SV40 were able to interrupt SV40 oncogenesis in the hamster. Thus, the TSTA of SV40-induced mouse sarcomas did not appear to be the same as the TSTA that appear on human, rat, and hamster cells transformed by SV40. Tumor antigen may be the immunizing component that has previously been isolated from mouse sarcoma cells, or there may be a peculiar histocompatibility barrier in the hamster to the immunogenicity of TSTA induced in mouse cells. (16 refs)

- 79-7041** Sarcomas Induced by Injection of Simian Virus 40 into Neonatal CFW Mice. (Eng) Hargis, B. J. (Sidney Farber Cancer Inst., Harvard Medical Sch., 44 Binney St., Boston, MA 02115); Malkiel, S. *J Natl Cancer Inst* 63(4): 965-968; 1979.

The role of malarial immunosuppression in the development of simian virus 40 (SV40)-induced tumors in mice was studied. Infection with murine malaria parasites, *Plasmodium berghei yoelii*, decreased the latency and increased the incidence and invasiveness of sarcomas induced in neonatal CFW mice by the iv injection of SV40. All mice that received both SV40 and *P. berghei yoelii* had liver and spleen sarcomas at 9 mo of age. At 11 mo of age, 70% of the SV40-inoculated mice had liver sarcomas indistinguishable from those in the group given both pathogens. Only one lung metastasis was seen in the SV40-treated group. The indirect immunofluorescence technique demonstrated the presence of SV40 T-antigen in the sarcomas. Among adult CFW mice given iv injections of SV40, only two tumors were found at 11 or 12 mo after virus inoculation. Both tumors were in the lungs; one was an adenoma and one was a papillary adenocarcinoma. Neither gave a positive reaction in the immunofluorescence test. (10 refs)

- 79-7042** Malignant Behaviour of Three Adenovirus-2-transformed Brain Cell Lines and Their Methyl Cellulose-selected Sub-clones. (Eng) Gallimore, P. H. (Dept. Cancer Studies, Medical Sch., Univ. Birmingham, Birmingham, B15 2TJ, England); McDougall, J. K.; Chen, L. B. *Int J Cancer* 24(4): 477-484; 1979.

Three adenovirus-2-transformed rat embryo brain cell lines and their methylcellulose-selected subclones were examined for fibronectin expression, anchorage-independent growth, saturation density, T antigen expression, and morphology. Tumorigenicity studies were carried out on newborn and rabbit anti-rat thymocyte serum-immunosuppressed syngeneic rats and congenitally athymic nude mice. With one exception the methylcellulose subclones contained significantly fewer fibronectin-positive cells than did the parent lines; a number of subclones contained no fibronectin-positive cells. Methylcellulose selection did not always alter cell morphology, saturation density or anchorage-independent growth as compared with parent lines. However, the methylcellulose subclones were considerably more malignant than the parent cell lines as measured by invasion and metastasis in nude mice. No in vitro characteristic correlated with malignant behavior. (17 refs)

- 79-7043** Intercistronic Complementation Between Adenovirus 2 Temperature-sensitive Mutants. (Eng) Plaat, D. (Department de Microbiologie, Centre Hospitalier Universitaire, Universite de Sherbrooke, Sherbrooke, Quebec J1H 5N4, Canada); Weber, J. *Virology* 98(1): 55-62; 1979.

The mechanism of intercistronic complementation was examined at the molecular level using well defined adenovirus type 2 temperature-sensitive (ts) mutants that map into discrete and separate regions on the adenovirus genome. In particular the synthesis of a 50K core-polypeptide, related to protein V, and the processing of core protein PVII were examined. The efficiency of complementation was unique to each mutant. Coinfection with wild-type virus failed to suppress completely the mutant phenotype, suggesting that the mutants were defective in non-catalytic proteins. Interserotype complementation between Ad2ts3, a hexon mutant, and Ad5ts22, a fiber mutant, resulted in mosaic virions with Ad2 fibers and Ad5 hexons, rather than in mosaic capsomeres. The putative hexon mutant, ts3, was found to exert a gene frequency-dependent dominance. Evidence suggesting that the ts3-specific 50K polypeptide may be a precursor to core protein V was obtained. It is concluded that complementation is profoundly influenced by the nature of the participating gene products and their function in virus infection. (26 refs)

- 79-7044** Spontaneous, Mutagen-induced and Adenovirus-induced Anchorage Independent Tumorigenic Variants of Mouse Cells. (Eng) Bellett, A. J. (Dept. Microbiology, John Curtin Sch. Medical Res., Australian Natl. Univ., Canberra, A.C.T. 2600, Australia); Younghusband, H. B. *J Cell Physiol* 101(1): 33-47; 1979.

Although normal C57 Black mouse embryo cells were not able to form colonies in agarose, rare variant (ar⁺) cell lines able to grow in agarose were established. Fluctuation analysis showed that ar⁺ variants arose by spontaneous mutation in the cultured cells. The frequency of ar⁺ variants was increased by treating cells with N-methyl-N'-nitro-N-nitrosoguanidine or ethyl methane sulfonate, or by abortive infection with human adenovirus type 5. Induced ar⁺ cells were fibroblastic; most grew slowly and had slightly reduced saturation density and increased serum requirements. Of twenty ar⁺ clones induced by Ad5, 14 were T-antigen-negative; two of these were also negative when tested for viral DNA. Six clones contained a few cells that were T-antigen-positive when first tested, but were negative when retested later. The ar⁺ variants were tumorigenic in athymic and in normal syngeneic mice. These results suggest that the ar⁺ phenotype can arise by spontaneous or

chemically induced mutation and can be induced by adenovirus through a process differing from classical transformation. (46 refs)

- 79-7045 Structure of Two Spliced mRNAs from the Transforming Region of Human Subgroup C Adenoviruses. (Eng) Perricaudet, M. (Unite de Genie Genetique, Institut Pasteur, 28 rue du Dr. Roux, 750 15 Paris, France); Akusjarvi, G.; Virtanen, A.; Pettersson, U. *Nature* 281(5733): 694-696; 1979.

Clones corresponding to the 12S and 13S messenger RNA (mRNA) from the transforming region (E1A) of human subgroup C adenoviruses were isolated and characterized by hybridization and sequence analysis. It was possible to combine sequence information from the clones with the genomic DNA sequence of adenovirus type 5 (Ad5) to deduce the structure of the 12S and 13S mRNAs from region E1A. The structure derived is based on the assumption that the 12S and 13S RNAs have common 5'- and 3'-ends. The polypeptides specified by the 13S and 12S mRNAs are predicted to be 288 and 242 amino acids long, with mol wts of 32,000 and 26,000, respectively. Both polypeptides should have identical amino- and carboxy-terminal ends, their only difference being a deletion of 46 internal amino acids from the polypeptide specified by the shorter mRNA. Both peptides should be unusually rich in proline and glutamic acid. It appears that more polypeptides have been assigned to region E1A than can be accounted for by the mRNAs observed by electron microscopy and the S₁ nuclease assay. Sequence analysis of additional clones will be required to resolve this problem. (22 refs)

- 79-7046 Tumorigenicity and Viral Gene Expression in Rat Cells Transformed by Ad 12 Virions or by *EcoRI* C Fragment of Ad 12 DNA. (Eng) Mak, S. (Dept. Biology, McMaster Univ., Hamilton, Ontario, L8S 4K1, Canada); Mak, I.; Smiley, J. R.; Graham, F. L. *Virology* 98(2): 456-460; 1979.

Several rat kidney cell lines transformed either by adenovirus 12 (Ad 12) virions or by the *EcoRI* C fragment (left 16%) of Ad 12 DNA were characterized with respect to viral DNA content, viral gene expression, and tumorigenicity. Virion-transformed cells contained viral DNA sequences from most regions of the viral genome while *EcoRI* C fragment-transformed cells contained only part of the C fragment. All cell lines transcribed DNA sequences from the left 6.7% (*HindIII* F fragment) of the genome; some lines also transcribed sequences extending into the adjacent *HindIII* H fragment. Virus-transformed and DNA-transformed lines induced tumors in immunocompetent rats with equal efficiency. (17 refs)

- 79-7047 Adenovirus Type 12 Tumor Antigen. II. Immunoprecipitation of Protein Kinase from Infected and Transformed Cells by Antisera to T Antigen and Some Normal Rat Sera. (Eng) Raska, K. (Dept. Pathology, Coll. Medicine and Dentistry, New Jersey-Rutgers Medical Sch., Piscataway, NJ 08854); Geis, A.; Fohring, B. *Virology* 99(1): 174-178; 1979.

Protein kinase was precipitated from adenovirus type 12 (Ad12)-infected KB cells and Ad12-transformed hamster cells by sera of tumor-bearing hamsters and rats. Immunoprecipitates obtained with T antigen reactive sera catalyzed transfer of ³²P from [γ -³²P]ATP to the γ -chain of IgG. In control cells, analogous products were without significant activity, and control hamster sera

did not precipitate protein kinase from infected and transformed cells. Some control rat sera (syngeneic with immune sera), however, did precipitate protein kinase from infected and transformed cells; sera of female breeder rats were particularly active. When partially purified, highly immunoreactive T antigen preparations from transformed cells were used as a source of enzymatic activity, protein kinase was detected only in precipitates obtained with immune sera. (16 refs)

- 79-7048 Tumor-specific Transplantation and Surface Antigen in Cells Transformed by the Adenovirus 12 DNA Fragments. (Eng) Shiroki, K. (Inst. Medical Science, Univ. Tokyo, 4-6-1, Shirokanedai, Minato-ku, Tokyo 108, Japan); Shimojo, H.; Maeta, Y.; Hamada, C. *Virology* 99(1): 188-191; 1979.

Adenovirus type 12 (Ad 12) tumor-specific transplantation antigen (TSTA) and surface (S) antigen were examined in 3Y1 rat cells transformed with Ad 12 DNA and its fragments. The cells used were WY3 (3Y1 cells transformed by whole Ad 12 DNA), CY1, (3Y1 cells transformed by the *EcoRI*-C fragment of Ad 12 DNA, GY cells (3Y1 cells transformed by the *HindIII*-G fragment of Ad 12 DNA), and HY cells (3Y1 cells transformed with the *BpaI*-H-fragment of Ad 12 DNA). The transformed cells (10⁶ to 5 x 10⁶) were transplanted sc into Fischer rats 1-28 days old. Tumor incidence was significantly different between the controls and animals immunized with WY3, CY1, or GY cells but not in those immunized with the HY cells. This suggests that TSTA of Ad 12 is present in WY3, CY1, and GY1 cells but not in HY cells. Membrane immunofluorescence demonstrated S antigen in WY3, CY21, and GY cells but not in HY cells. These results show that WY3, CY1 and GY cells contain TSTA and S antigen in addition to the previously demonstrated T antigen and suggest that all of these antigens contain a protein(s) coded for by the Ad 12 transforming gene, which is located on the left end (7.2%) of the viral genome. The results also suggest that the genetic information needed for the initiation of transformation is contained in map unit 1-4.5 and that needed for maintenance of transformation in map unit 4.5-7.2. (18 refs)

- 79-7049 Development and Alternate Changes of Surface Antigen in Adenovirus Type 12-transformed Cells. (Eng) Hamada, C. (Sch. Medicine, Niigata Univ., Asahimachi 1-757, Niigata 951, Japan); Maeta, Y. *Gann Monogr Cancer Res* 23: 175-180; 1979.

A virus-specific surface (S) antigen in adenovirus type 12 (Ad12)-transformed cells underwent alternate changes in vitro and in vivo. In a fluorescent antibody test, while all of the hamster and mouse cells transformed in vitro with Ad12 were positive for the S antigen, tumor cells in vivo, produced by grafting the transformed cells, were negative [S(+) and S(-), respectively]. Conversely, the S(-) cells could be converted to S(+) by repeated subcultures in vitro or by Ad12 infection. In addition, H-2 antigens in Ad12-transformed mouse cells were no longer detectable after allografting. The various phenotypes of Ad12-transformed cells thus obtained were examined for their immunological properties. S(+) cells were more immunosensitive and less tumorigenic than S(-) cells. Coexistence of the S and H-2 antigens was required for cells to be injured by immune spleen cells. These findings are discussed from the viewpoint of tumor immunity. (15 refs)

- 79-7050 Structure and Function of Adenovirus Type 12 Defective Virions. (Eng) Mak, I. (Dept. Biology, McMaster

Univ., Hamilton, Ontario, L8S 4K1, Canada); Ezoe, H.; Mak, S. *J Virol* 32(1): 240-250; 1979.

Adenovirus type 12 preparations purified from human KB cells contained defective virions with a lighter density. The light virions were separated by banding in CsCl density gradients. Ultrastructural examination of DNA extracted from the light virions indicated that it was 3%-3.5% shorter than DNA from complete virions. Ultrastructural findings, restriction endonuclease analysis, and the results of DNA-DNA hybridization experiments indicated that about 50% of the DNA molecules from the light virions contained deletions ranging 4.5% to 8%, mapping near 16% from the left-hand end of the genome. The plaquing efficiency of the light virions was 5%-14% that of the complete virions. By the immunofluorescence technique, the light virions were shown to induce early (T-antigen) and late viral structural polypeptides (V-antigen) as efficiently as the complete virions. The light virions also induced tumors in newborn hamsters with the same efficiency as the complete virions. These results indicate that the deleted regions of the genome are not essential for late gene expression. (35 refs)

- 79-7051 In Vivo and In Vitro Biological Activity of an Oncogenic DNA Virus (Cancer Virus). (Spa) Alvarez Noves, J. (Departamento de Biología y Bioquímica de Cáncer, Instituto Nacional de Oncología, Ciudad Universitaria, Madrid-3, Spain); Alvarez Rodriguez, Y.; Valladares, Y. *Rev Esp Oncol* 25(3): 377-383; 1978.

The biological activity of an oncogenic DNA virus (cancer virus, CV) was studied in vitro in a cell line (ERGA) established from mouse embryo cells and in vivo in *Mesocricetus auratus*. The in vitro tests demonstrated cell degeneration, increased phagocytosis by the surviving cells, reduction of the mitotic activity, and the appearance of foci of cellular transformation. The transformed cells did not release virus. Golden hamsters were followed for up to 12 mo after sc injection of CV from the ERGA cell cultures; 77 of the 105 animals developed at least one tumor. Tumors included 50 multicentric fibrosarcomas of the heart, 12 polymorphous epithelial thymomas, 3 pleomorphic tubular carcinomas of the kidney, 24 polymorphocellular sarcomas of the sc tissue (usually at or near the injection site), and 2 other tumors. Most tumors were found within the first 3 mo after inoculation. (9 refs)

- 79-7052 Oncornavirus-like Particles Released by Human Prostatic Explant Cultures. (Eng) Job, L. (Dept. Viral Oncology, Roswell Park Memorial Inst., Buffalo, NY 14263); Arya, S. K.; Carter, W. A.; Horoszewicz, J. S. *Oncology* 36(6): 248-253; 1979.

Epithelial explant cultures from several human prostatic tissues released oncornavirus-like particles. The extracellular particles, obtained from culture medium conditioned by the explants, banded at a density of 1.1-1.2 g/cm³ in a sucrose density gradient. The particles contained RNA-directed DNA polymerase that utilized poly (2'-O- (2'-O-methylcytidylic acid) as a template, and showed preference for polyadenine over poly-d-adenine and manganese over magnesium. The particles also contained RNA that directed DNA synthesis in vitro. The synthesized DNA was associated with RNA, some of which was high-mol-wt RNA. Explant cultures from 5/15 hyperplastic prostatic specimens and 3/4 prostatic adenocarcinoma specimens released particles that banded at a density of 1.1-1.2 g/cm³ and contained RNA-directed DNA

polymerase. Explant cultures from two normal prostates did not release such particles. No particles were found in the culture medium conditioned from monolayers of monkey-kidney CV-1 cells. (21 refs)

- 79-7053 Characterization of Infectious Oncornaviruses from MOPC-460 Plasmacytomas: Their Relation to A-Type Particles. (Eng) Ramabhadran, T. V. (Dept. Biology, Washington Univ., St. Louis, MO 63130); Hartley, J. W.; Rowe, W. P.; Godefroy-Colburn, T.; Jhabvala, P. S.; Thach, R. E. *J Virol* 32(1): 123-130; 1979.

MOPC-460 plasmacytoma cells grown in tissue culture produce intracellular A-type particles and closely related extracellular oncornavirus-like particles (myeloma-associated virus: MAV); an attempt was made to transmit MAV to homologous (mouse) and heterologous (mink) cells. This resulted in the isolation of ecotropic and xenotropic infectious forms of murine leukemia virus (MuLV). The relationship of these two isolates (MuLV_{eco} and MuLV_{xeno}) to A-type particles and to MAV was investigated by nucleic acid hybridization. Using complementary DNA probes prepared from MuLV_{eco} and MuLV_{xeno}, these infectious MuLV were found to differ from A-type particles and from MAV. It was also found that MAV was the predominant extracellular component; MuLV_{eco} and MuLV_{xeno} were present at low levels (<5%) in MAV preparations. Ultrastructure examination showed that neither mouse embryo cells infected with MuLV_{eco} or mink cells infected with MuLV_{xeno} contained cytoplasmic A-type particles. MuLV_{eco} and MuLV_{xeno} appear to be BALB/c endogenous viruses that are induced when MOPC-460 solid tumor cells are adapted to growth in cell culture. The inability to transfer MAV into cells permissive to MuLV of ecotropic or xenotropic host range suggests that MAV may be defective and/or noninfectious. (36 refs)

- 79-7054 Characterization of the Proteins of Intracisternal Type A and Extracellular Oncornavirus-like Particles Produced by MOPC-460 Myeloma Cells. (Eng) Robertson, D. L. (Dept. Microbiology, Univ. California, San Francisco, CA 94143); Jhabvala, P. S.; Godefroy-Colburn, T.; Thach, R. E. *J Virol* 32(1): 114-122; 1979.

The mouse plasmacytoma cell line MOPC-460 produces both intracisternal and intracytoplasmic A-type particles when grown as a solid tumor. When these cells are grown either as an ascites tumor or in tissue culture, a third type of particle is produced extracellularly. This particle, the 'myeloma-associated virus,' is closely related to, and probably an alternate form of, the intracisternal A-type particle. The proteins present in these two particles were compared by tryptic peptide mapping. Both types of particles were found to contain essentially the same major proteins of 76,000 (p76) 68,000 to 70,000 (p68-70), and 45,000 (p45) daltons as well as varying amounts of smaller proteins. The relative proportions of all these proteins varied from preparation to preparation in an unpredictable way. The p45, p68, and p70 proteins all contained sequences found in p76, suggesting precursor-product relationships of p76 to p70 to p45 for solid tumor A-type particles and p76 to p68 to p45 for extracellular myeloma-associated virus. In addition, immune precipitation experiments established that p76 contains at least some of the antigenic determinants characteristic of murine leukemia virus p30. This confirms earlier nucleic acid hybridization studies indicating a moderate degree of relatedness between MOPC-460 A-type particles and several standard murine leukemia and sarcoma viruses. Taken together, these

VIRAL CARCINOGENESIS

results provide evidence supporting the concept that MOPC-460 A-type particles may represent aberrant forms of C-type murine viruses. (47 refs)

- 79-7055 Tumorigenicity and Intracisternal A-Particle Expression of Hybrids Between Murine Myeloma and Lymphocytes. (Eng) Giacomoni, D. (Dept. Microbiology and Immunology, Univ. Illinois Medical Center, Chicago, IL 60612). *Cancer Res* 39(11): 4481-4484; 1979.

Hybrids of BALB/c lymphocytes and a murine myeloma that expresses intracisternal A-particles were obtained with polyethylene glycol as the fusogen. The karyotype, tumorigenicity, and A-particle expression of the hybrid clones were assessed. All the hybrid clones analyzed were tumorigenic and expressed intracisternal A-particles even when they were the result of a fusion event between two lymphocytes and one myeloma cell in which no loss of chromosomes was detected. The tumors that developed following inoculation of hybrid cells into BALB/c mice (1×10^6 cells/mouse) were karyotypically identical to the inoculated cells. It appears that the two myeloma cell phenotypic traits analyzed (tumorigenicity and A-particle expression) are dominant. (23 refs)

- 79-7056 In Vivo Infectivity of the Fibrotropic C-Type Viral Isolates From C57BL/Ka Mice. (Eng) Decleve, A. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Lieberman, M.; Boniver, J.; Kaplan, H. S. *Cancer Res* 39(11): 4322-4329; 1979.

One of the three nontumorigenic fibrotropic C-type viral isolates from C57BL/Ka mice, the BL/Ka(B) virus (which is the only one of the three capable of infecting normal hematopoietic and lymphoid cell populations of C57BL/Ka mice in vivo), was studied. Inoculation of this virus alone into neonates resulted in transient replication in the bone marrow, spleen, and occasionally the thymus. Thymocytes could, however, be permanently infected in such animals if BL/Ka(B) virus was coinoculated with the xenotropic BL/Ka(X) virus. Neonatal injection of BL/Ka(B) prior to fractionated whole-body irradiation yielded an increase in the percentage of virus-productive radiogenic lymphomas but a decrease in the incidence of this tumor. Injection of BL/Ka(B) into normal adult C57BL/Ka mice did not yield overt expression of virus replication in any tissues tested; latent infection could, however, be detected in the marrow and in the reticuloepithelium of the thymus. Whole-body x-irradiation of adults with 400 rads partially restored neonatal susceptibility of bone marrow cells to infection. BL/Ka(B) injection after fractionated whole-body irradiation of weanling C57BL/Ka mice increased the percentage of virus-positive lymphomas; in addition, a bone marrow cell subpopulation permissive for infection by the virus increased greatly soon after irradiation. (29 refs)

- 79-7057 A New Endogenous Primate Type C Virus Isolated from the Old World Monkey *Colobus polykomos*. (Eng) Sherwin, S. A. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD); Todaro, G. J. *Proc Natl Acad Sci USA* 76(10): 5041-5045; 1979.

A new, genetically transmitted retrovirus (CPC-1) was isolated from the Old World monkey *Colobus polykomos* and was readily transmitted to both feline and human cells in culture. Nucleic acid

hybridization studies revealed 50-70 copies of the CPC-1 genome in *C. polykomos* cellular DNA. Since related virologic sequences were detected in the DNA of all other Old World monkeys, as well as in the DNA of at least one ape species, the chimpanzee, this virus appears to have been genetically transmitted in primates for 30-40 million yr. CPC-1 showed a partial relationship to the type C virus previously isolated from stump-tail monkeys (MAC-1), as indicated by nucleic acid sequence homology, antigenic cross-reactivity of the major viral structural proteins, and similar host range in vitro. It was concluded that CPC-1 and MAC-1 belong to the same class of genetically transmitted primate type C viruses and as such represent the first example in primates of analogous endogenous retroviruses isolated from two distantly related species. (26 refs)

- 79-7058 Analysis of the Properties of a New Antigen Associated with Oncornavirus D. (Rus) Kosiakova, N. P. (D. I. Ivanovskii Inst. Virology, Moscow, USSR); Posevaia, T. A.; Zhdanov, V. M. *Vopr Virusol* (4): 381-385; 1979.

Properties of a new antigen associated with oncornavirus D were evaluated. HEp-2 cells or L 929 murine fibroblasts were infected with oncornavirus D and then incubated with the labeled precursors. The soluble antigens were obtained by solubilization with detergents; the presence of soluble antigen in the supernatant was assessed by the complement fixation reaction (CFR) with specific rabbit antiserum. The final precipitate was analyzed by polyacrylamide gel electrophoresis. Both HEp-2 and L 929 cells contained the peak of radioactivity corresponding to a protein with a mol wt of 98,000-100,000 daltons. (13 refs)

- 79-7059 Unusual Features of the Oncogenicity of Chicken Embryo Lethal Orphan (CELO) Virus in Hamsters. (Eng) Asch, B. B. (Dept. Pathology, Beth Israel Hosp., Boston, MA 02215); McCormick, K. J.; Trentin, J. J. *Prog Exp Tumor Res* 23: 56-88; 1979.

Previous studies concerning the in vitro and in vivo malignant transformation of hamster cells by chicken embryo lethal orphan (CELO) virus are reviewed, and the results of recently conducted studies are presented. No single characteristic morphologic pattern of CELO virus-transformed tumor cells was identified in the present studies; the morphology of such cells appeared to depend to some extent on the source of the cell. Alternatively, CELO virus may interact differently with the same type of target cell, thereby giving rise to distinctive morphology. Successful quantitative transformation procedures were dependent on conditions that restricted growth of normal cells. Expression of CELO virus-specific T-antigen varied in both the tumor and transformed cells induced by CELO virus, and it is likely that the synthesis of this antigen may in some cases be repressed in a tumor cell and then resumed at a later time under suitable conditions. It appears that the CELO virus T-antigen is not necessary for the maintenance of transformation induced in vivo or in vitro. There may be separate genes for CELO virus T-antigen and tumor-specific transplantation antigen in that the lack of the former did not affect the expression of the latter in CILT/2 cells. All of five cell lines established from CELO virus-induced tumors contained at least one type of virus-like particle (VLP), and two of four lines derived from cells transformed in 2% fetal calf serum had VLP detectable by electron microscopy. There is no evidence that indigenous VLP of the hamster are more than passengers in CELO virus-induced tumors. (68 refs)

- 79-7060 Avian Acute Leukemia Virus MC29: Conserved and Variable RNA Sequences and Recombination with Helper Virus. (Eng) Duesberg, P. H. (Dept. Molecular Biology, Univ. California, Berkeley, CA 94720); Bister, K.; Moscovici, C. *Virology* 99(1): 121-134; 1979.

The RNAs and proteins of five laboratory strains of defective avian acute leukemia virus MC29 were investigated for genetic variations. The RNAs shared 20 conserved T₁-oligonucleotides (ON) and differed in specific sets selected from 10 variable ON. Since some, but not all, variable and some conserved MC29-ON were shared with helper viruses, and since the 5' cap-ON of MC29 RNA rescued from the same nonproducer cell varied with that of the helper virus RNA, it was concluded that genetic variations in MC29 include recombination with helper virus. Oligonucleotide maps of the five MC29 RNAs showed eight variable ON in their 3' group-specific sections, only conserved ON in their internal-specific section, and mostly conserved ON in their 5' group-specific section (with the exception of variable 5' cap-ON and a lack of internal ON in one strain). The 110K proteins of the five strains were electrophoretically indistinguishable. The ratio of MC29 RNA to helper virus RNA in virions reflected, by a constant, the ratio of 110K MC29 to helper viral proteins in transformed cells. MC29 RNA appears to consist of two genetic units: one made of highly conserved 5' and internal-specific RNA sections, which codes for the 110K protein and appears to serve a primary function in oncogenicity; and the other made of the variable 3' group-specific RNA sections, which may affect oncogenicity indirectly. (36 refs)

- 79-7061 Role of Envelope Proteins of Paramyxoviruses in the Modification of Cell Membrane Antigens. (Eng) Eaton, M. D. (Dept. Medical Microbiology, Stanford Univ., Stanford, CA 94305). *Arch Virol* 61(4): 327-336; 1979.

The role of envelope proteins of paramyxoviruses in the modification of cell membrane antigens was studied. Modified Newcastle disease virus, and Sendai virus or virus fractions were used to immunize C3H/Bi/G mice. The effect of viral preparations with reduced F (fusion) protein activity was compared with that of equivalent amounts of active or inactive virus as measured by hemagglutination. Viral preparations without hemolytic activity showed diminished adsorption to tumor cell (ascites lymphoma induced by the Gross murine leukemia virus) membranes, and the immune response to these membranes in syngeneic hosts was diminished. An immunogenic material associated with paramyxovirus antigens was extracted from membranes with Triton X100 and desoxycholate. The results indicate that the F protein is a major factor in permanent adsorption and in causing cell membrane antigens to become immunogenic in syngeneic hosts. (21 refs)

- 79-7062 Histological and Cytological Evidence of a Condylomatous Lesion in Association with an Invasive Carcinoma of Uterine Cervix. (Eng) Syrjanen, K. J. (Dept. Pathology, Pajjat-Hame Central Hosp., Lathi, Finland). *Arch Geschwulstforsch* 49(5): 436-443; 1979.

A 38-yr-old woman underwent colposcopic examination after routine cytological smears showed cells suggesting epithelial dysplasia. Wartlike punctate areas and mosaic patterns were present in the cervical epithelium. Biopsy was indicative of carcinoma in situ, and conization was performed. The conization specimen yielded the diagnosis of invasive squamous cell carcinoma. Examination of the smears confirmed the presence of small dyskaryotic superficial keratinized cells derived from the superficial keratotic layers of condylomatous epithelium. Condylomatous intermediate cells and superficial cells with perinuclear halos were also present. In the colposcopy specimens, epithelial lesions typical of flat-type condyloma were found close to and mixed with the dysplastic areas. In the conization specimens, condylomatous lesions were closely associated with the invasive carcinoma. The patient underwent a Wertheim operation combined with radiotherapy, and was disease-free 16 mo later. Follow-up for any woman with condyloma cells in cervical smears is strongly recommended. (24 refs)

- 79-7063 Hepatitis B Virus Antigens in Human Primary Hepatocellular Carcinoma Tissues. (Eng) Goudeau, A. (Facultes de Medecine et de Pharmacie, Institut de Virologie, 2 bis, Boulevard Tonnelles, 37000 Tours, France); Maupas, P.; Coursaget, P.; Drucker, J.; Chiron, J. P.; Denis, F.; Diop Mar, I. *Int J Cancer* 24(4): 421-429; 1979.

The presence of hepatitis B virus (HBV) antigens was examined in specimens of liver tissue obtained at necropsy from black Senegalese patients suffering from primary hepatocellular carcinoma (PHC). The results were correlated with markers of hepatitis B infection in serum. Examination of 15 liver extracts for hepatitis B surface antigen (HBsAg) and core antigen (HBcAg) revealed HBsAg in 10/12 cases with HBsAg-positive serum and HBcAg in 3 cases. The HBsAg was detected in seven of eight livers by immunofluorescence and orcein staining. HBsAg-positive cells were located mainly in the peri-tumoral cirrhotic tissue, although positive hepatocytes were also found in tumor nodules in liver from one of the patients. HBcAg was found in five of seven cases by immunofluorescence in hepatocytes of the cirrhotic areas. HBcAg fluorescence was primarily nuclear but, in some lobules, a patchy cytoplasmic fluorescence was observed, suggesting a cytoplasm-nucleus pathway in the synthesis of the HBV core antigen. Electron microscopy was performed on two HBsAg- and HBcAg-positive cases. Fibrillar and crystalline cytoplasmic inclusions were observed in tumor cells. In the same cells, 20-25 nanometer virus-like particles were present in swollen cisternae of the endoplasmic reticulum. (34 refs)

IMMUNOLOGY

- 79-7064 Rejection of Adenovirus 2-transformed Cell Tumors and Immune Responsiveness in Syrian Hamsters. (Eng) Cook, J. L. (Natl. Inst. Allergy and Infectious Diseases, NIH, NCI, Bethesda, MD 20205); Kirkpatrick, C. H.; Rabson, A. S.; Lewis, A. M. *Cancer Res* 39(12): 4949-4955; 1979.

When newborn hamster tumor lines induced by adenovirus type 2-transformed cells were transplanted to older hamsters (sucklings 4-21 days old, weanlings after 21 days), the cell-mediated host defenses responsible for tumor graft rejection matured early in the second wk of life. Light microscopic examinations performed during the course of tumor development showed that the primary histopathological difference between progressing tumors removed from newborn or thymectomized weanling hamsters and regressing lesions from normal weanlings was the lack of an early, mononuclear cell infiltrate in neoplasms from newborn and thymectomized hosts. These results suggest that the maturation of cellular immunity determines resistance to tumor transplantation in this system. This conclusion was supported by the in vitro detection of concanavalin A-responsive lymphocytes in spleens from tumor-resistant suckling but not tumor-susceptible neonatal hamsters. Although the incomplete seeding of thymus-dependent lymphocytes to the peripheral lymphoid tissues of newborn hamsters may partially explain the deficient concanavalin A responses of neonatal spleen cells, there appears to be an additional requirement for a radioresistant, adherent accessory cell population. These findings suggest that the development of a cell-mediated immune response is necessary for the rejection of adenovirus type 2-transformed cells and transformed cell-induced tumors and that this response requires the interaction of T-cells and accessory cell populations. (21 refs)

- 79-7065 Suppression of the Immune Response in Tumor-bearing Mice. II. Characterization of Adherent Suppressor Cells. (Eng) Bluestone, J. A. (Lab. Herpes Virus Infection, Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Lopez, C. *J Natl Cancer Inst* 63(5): 1221-1227; 1979.

The results of experiments in which adherent spleen cells from late (≥ 18 days postinoculation) tumor-bearing BALB/c mice suppressed lymphoproliferative and effector immunity, as evaluated by the mixed leukocyte culture and cell-mediated lympholysis assays, are reported. Procedures that eliminated T-cells or B-cells while enriching for macrophage populations significantly augmented the suppression, whereas removal of phagocytic and adherent cells abrogated the suppressive effect. It is concluded that the cells responsible for the suppression of cell-mediated immune responses in late tumor-bearing mice were of the monocyte-macrophage series. Furthermore, the suppressive influence was not due merely to the increased number of macrophages in tumor-bearing animals. The experiments clearly showed that the splenic macrophages, even at low concentrations, demonstrated a suppressive function. (33 refs)

- T. (Dept. Immunology, Res. Inst. Tuberculosis and Cancer, Tohoku Univ., Seiryomachi 4-1, Sendai 980, Japan); Tachibana, T. *Gann Monogr Cancer Res* 23: 247-254; 1979.

Immune responses induced by inoculation of hybrid cells into normal and tumor-bearing C3H mice were studied. Primary tumor cells induced in a C3H mouse by 3-methylcholanthrene were fused with 8-azaguanine-resistant L cells, yielding two hybrid clones: hybrids of two tumor cells with one L cell; and hybrids of one tumor cell with one L cell. Both hybrid types expressed H-2k antigen, the tumor cell antigen, and L-cell antigen, and failed to produce tumors in a normal C3H mouse following ip or sc injection of 10^6 cells. Normal mice inoculated with hybrid cells were resistant to subsequent challenge with the parental tumor cells, the growth of tumor cells being suppressed by splenic lymphoid cells from the resistant mice. Suppression of tumor growth was also observed with immune splenic lymphoid cells passed through a nylon fiber column, but not with immune splenic cells treated with anti-Thy-1.2 serum and complement. When hybrid cells were injected into parental tumor-bearing mice, tumor growth was enhanced and cytotoxic T cells were generated. Elevated levels of antibody to the tumor cells and antigen-antibody complex were detected in the sera from these mice compared with sera from untreated tumor-bearing mice. The sera of the hybrid-cell-treated tumor bearers blocked at the level of the target cells and also inhibited the reactivity of immune spleen cells in vitro. It is concluded that the injection of viable hybrid cells can preferentially stimulate cellular immunity in normal mice while accelerating the humoral response in tumor-bearing mice, resulting in enhanced tumor growth. - 79-7067 Expression of the Transformed Phenotype and Tumorigenicity in Somatic Cell Hybrids. (Eng) Marshall, C. J. (Dept. Molecular Genetics, Sidney Farber Cancer Inst., Boston, MA 02115). *J Cell Sci* 39: 319-327; 1979.

Two TA3B x REF and four BI x TA3B hybrids that show suppression of the transformed phenotype were tested for tumorigenicity in nude mice. Aliquots of cell suspensions (10^6 , 10^5 , and 10^3 cells) were injected sc into the rear flank of male nu/nu nude mice, 6-12 wk old. No tumors were produced from either of the two TA3B x REF hybrids, each of which contained one genome from each tumor producing parental strain, suggesting that both tumorigenicity and the transformed phenotype are very stably suppressed. BI x TA3B hybrids produced tumors in nude mice; these tumors arose after long latent periods (40-70 days), suggesting the selective outgrowth of a subset of variant hybrids. Selection in culture for anchorage-independent growth selected for tumorigenicity. Tumorigenic variants always exhibited an altered cytoskeleton. Variants selected in culture for the expression of the transformed phenotype did not show suppression of tumorigenicity, and variants selected for tumorigenicity expressed some (but not necessarily all) characteristics of the transformed phenotype, suggesting that the selected variant is not the only type that can be derived from a suppressed hybrid. - 79-7068 Depression of Vaccinal Immunity to Marek's Disease by Infection with Reticuloendotheliosis Virus. (Eng)

Witter, R. L. (Regional Poultry Res. Lab., Science and Education Admin., Agricultural Res., US Dept. Agriculture, East Lansing, MI 48823); Lee, L. F.; Bacon, L. D.; Smith, E. J. *Infect Immun* 26(1): 90-98; 1979.

The effect of infection with low-virulence, tissue culture-propagated strains of reticuloendotheliosis virus (REV) on protective vaccinal immunity against Marek's disease (MD) lymphomas was investigated. Vaccinated chickens inoculated at hatching with $>10^4$ focus-forming units of REV and challenged with MD virus were poorly protected against MD lesion development; protective indices were 53-79% for strain CS ($p < 0.05$) and 42-49% for strain T ($p < 0.01$) compared to 78-100% for REV-free controls. Furthermore, the response of blood lymphocytes to mitogen stimulation and the antibody response to sheep erythrocytes and *Brucella abortus* were less in REV-inoculated chickens than in controls. The REV-induced depression of immune responses was more severe in chickens infected with mildly pathogenic strain T than in chickens infected with the apathogenic strain CS and was generally transient with both virus strains. Little or no depression of immune responses was observed in chickens inoculated with $<10^3$ focus-forming units of REV. These studies extend knowledge on the immunodepressive ability of low-virulence REV strains, establish that infection with these viruses depresses certain parameters of MD vaccinal immunity, and provide an important model for cellular immunity against virus-induced neoplasia in the chicken. (52 refs)

79-7069 Effect of Different Components of the Thymic Stroma on the Onset of AKR Leukaemia. (Eng) Fournier, M. (Immunology Res. Center, Institut Armand-Frappier, 531 des Prairies Blvd., P. O. Box 100, Laval-des-Rapides, Laval, Quebec, Canada); Potworowski, E. F. *Clin Exp Immunol* 37(3): 512-516; 1979.

Female AKR mice received weekly ip injections of one organ equivalent dose of insoluble thymic fraction (ITF) or soluble thymic fraction (STF) starting at 60 days of age and ceasing at the onset of leukemia. Three control groups [uninjected, injected with soluble spleen factor (SSF), and injected with insoluble spleen factor (ISF)] were established, with the latter two groups injected according to the same protocol used for the STF and ITF. The survival curves of the three control groups were similar, with death by leukemia beginning at day 225 and the 50% survival point reached at day 300. In the group injected with ITF, mice began to die at day 160; and the 50% survival point was reached at day 250. In the group injected with STF, mortality began at the same time as in the control groups; but the curve fell much more slowly. At the end of the experiment on day 350, 66% of the mice were still alive compared to 35% in the control groups. Preleukemic mice of 2, 4, 5, and 6 mo of age were sacrificed and their thymuses examined by immunofluorescence with anti-ITF and anti-STF sera. Strong positive fluorescence was obtained with anti-ITF in preleukemic and leukemic mice. Anti-STF staining was strong during the preleukemic period but could not be detected in the thymuses of leukemic mice. The acceleration of leukemia by ITF injections is in accordance with the hypothesis that an accumulation of thymocyte precursors is associated with the triggering of the disease. In the STF-injected group, the injected STF probably prevented the accumulation of lymphoblastoid cells. The results suggest disturbances in equilibrium between tumor-enhancing and fully differentiated immunocompetent T cells. (21 refs)

79-7070 Suppression of T Cell-mediated Immunity by Tumor Cells: Immunogenicity Versus Immunosuppression

and Preliminary Characterization of the Suppressive Factors. (Eng) Ting, C. C. (Lab. Cell Biology, NCI, Bethesda, MD 20014); Rodrigues, D.; Ting, R. C.; Wivel, N.; Collins, M. J. *Int J Cancer* 24(5): 644-655; 1979.

The effect of tumor cells (the Friend virus-induced FBL-3 and HFL/d leukemias and the chemically-induced EL-4 tumor and Meth A sarcoma) on the induction of cytotoxic T lymphocytes (CTLs) to alloantigens was studied using female C57BL/6 and BALB/c mice. The tumor cells were poorly immunogenic and were immunosuppressive as shown by their ability to suppress standard mixed lymphocyte culture reactions. This suppression acted mainly at the induction phase of the cytotoxic response and was not able to interfere with the killing activity of fully generated CTLs. In the FBL-3 system, at least two major components contributed to immunosuppression, one of viral and the other of nonviral origin. The viral component was sensitive to UV irradiation and could be pelleted after ultracentrifugation at 100,000 g. The non-viral component was UV-resistant and was retained in the supernatant fraction after ultracentrifugation. Friend virus and 12 commonly found murine viruses were excluded as possible causes for the immunosuppression; the immunosuppressive viruses are probably of endogenous origin and are defective in replication. The findings indicate that all tumor cells probably possess the immunosuppressive factor(s), which may account for their apparent lack of immunogenicity and the lack of proper immune response in the tumor-bearing hosts. (37 refs)

79-7071 Antigenic Expression in Somatic Hybrids and the Use of Cell Fusion in Tumor Xenogenization. (Eng) Klein, G. (Dept. Tumor Biology, Karolinska Inst., S-104 01 Stockholm 60, Sweden). *Gann Monogr Cancer Res* 23: 225-238; 1979.

Evidence for antigenic expression in somatic cell hybrids is discussed. Genetically determined antigens show a codominant (autonomous) expression, with the exception of hybrids produced by fusing the H-2-negative Ehrlich ascites tumor cells with other cells. In the latter case, the antigenic expression of the partner is suppressed but can reappear after chromosome losses. Fusion of β_2 -microglobulin- and HLA-negative Daudi cells with microglobulin-positive mouse or human cells leads to a reexpression of the missing HLA, and fusion of the TA3/Hauschka ascites tumor (low H-2 antigen expression) with normal fibroblast partners with different H-2 specificity leads to full reexpression of H-2a. Antigens and other markers related to differentiation are usually suppressed when expressor cells of a given lineage are fused with nonexpressor cells of a different lineage. In contrast, when expressor and nonexpressor cells of the same lineage are fused, codominant expression appears to be the rule. Virally determined and tumor-associated antigens show a wide range of behaviors. (45 refs)

79-7072 Humoral Reactions of BALB/c Mice during Tumor Induction by Moloney Sarcoma Virus. (Rus) Yakimenko, L. V. (Dept. Immunology Carcinogenesis, Inst. Problem Oncology, Kiev, USSR); Vetrova, E. P.; Kaminskaia, L. P.; Berdova, A. G.; Umanskii, Iu. A. *Vopr Onkol* 25(9): 46-50; 1979.

A study was designed to evaluate the humoral response in mice during tumor development induced by Moloney sarcoma virus (MSV). BALB/c mice were inoculated im with MSV. Antibody levels in the whole serum and its fractions as well as the number of antibody-forming cells (AFC) in the spleen were determined within

different time periods of inoculation. It was found that tumorigenesis did not affect the cytotoxicity of whole serum. The cytotoxic activity of the IgM-fraction increased in the middle of tumorigenesis, then decreased at the terminal stage, while cytotoxic activity of the IgG-fraction showed a progressive increase throughout the entire process of tumorigenesis. The number of AFC showed marked decrease (approx fourfold) during the period of max tumor development, while tumor regression was associated with an increase in the number of cells producing both 7S- and 19S-antibodies. (11 refs)

- 79-7073 Regulation of Granulopoiesis In Vitro. (Eng) Moore, M. A. (Dept. Developmental Hematopoiesis, Sloan-Kettering Inst. Cancer Res., New York, NY 10021). In: *Hematopoietic Cell Differentiation. Proceedings of the ICN-UCLA 1978 Symposium on Molecular and Cellular Biology held in Keystone, CO, 10 March 1978*. Golde, D. W.; Cline, M. J.; Metcalf, D.; Fox, C. F., eds. (New York: Academic Press) Vol. 10, 504 pp.; 445-459; 1978.

Studies concerning the regulation of granulopoiesis in vitro are reviewed. Mature granulocytes and their products indirectly inhibit granulocyte-macrophage progenitor cells (CFU-c) in vitro by decreasing the production and release of colony-stimulating factors (CSF) by monocytes and macrophages. Granulocyte colony-inhibiting activity (CLA) has no inhibitory effect on colony formation stimulated by an exogenous source of CSF and does not act directly on CFU-c or on the CSF molecule. Studies of CIA in the granulocytes of patients with chronic myeloid leukemia suggest that the production and response to CIA are quantitatively, not qualitatively, defective in this disease. The capacity of serum to stimulate granulocytic colony formation in vitro involves at least three types of activities: CSF, potentiating factors that enhance CSF action, and inhibitory factors with various degrees of specificity. Macrophages elaborate prostaglandin E (PGE) in response to macrophage-activating agents. The extent of prostaglandin synthesis is determined by the concentration of CSF to which the cells are exposed, which suggests that PGE may play a physiological role in limiting the positive feedback of macrophage-derived CSF. Some retention of regulatory responsiveness was observed in myeloid leukemias, particularly a dependence on CSF for in vitro proliferation of leukemic cells from patients with acute and chronic myeloid leukemia. In vitro transformation of continuous bone marrow cultures with Friend virus produced phenotypic changes comparable to those seen with human myeloid leukemia. These in vitro studies demonstrate that a subtle regulatory imbalance may play a major role in clonal dominance of transformed pluripotential stem cells and committed granulopoietic progenitor cells. (24 refs)

- 79-7074 Fc Receptors on Myeloid Leukaemic Cells: Comparison Between Assays of Rosette-forming Cells. (Eng) Ridway, J. C. (Dept. Pathology, Victoria Hosp., Blackpool FY3 8NR, England); Taylor, G. M.; Harris, R. *J Immunol Methods* 29(3): 271-277; 1979.

The ability of sheep RBC sensitized with rabbit anti-sheep RBC antibody (SEA) and human anti-D-coated RBC (HEA) to identify Fc receptors on blood WBC from normal individuals and from patients with myeloid leukemia was compared using the rosette-forming cells (RFC) assay. Differences were found between the assays in both groups, indicating the heterogeneity of Fc receptors with respect to affinity for marker and for Fc-bearing WBC. In

normal cells, WBC formed more rosettes with the SEA marker, while in several different myeloid leukemias, there were generally more HEA-RFC than SEA-RFC. This was particularly noticeable when the proportion of monocytoid cells in the blood was high. The variability of results seen between markers and within morphologically determined types in myeloid leukemia could be due to heterogeneity in expression of the receptor, and the Fc receptor density may be increased in active cells of a malignant disease. Although SEA are more efficient than HEA for the detection of Fc receptors on normal WBC and neutrophils, the usefulness of SEA in detecting myelomonocytic blasts is limited unless the blood is first depleted of lymphocytes and neutrophils. (8 refs)

- 79-7075 Rapid In Vivo Assay of Mouse Natural Killer Cell Activity. (Eng) Riccardi, C. (Inst. Pharmacology, Univ. Perugia, 06100 Perugia, Italy); Puccetti, P.; Santoni, A.; Herberman, R. B. *J Natl Cancer Inst* 63(4): 1041-1045; 1979.

Rapid elimination of tumor cells from some organs was detected in mice following the iv injection of tumor cells labeled in vitro with [¹²⁵I]5-iodo-2'-deoxyuridine. Recovery of radioactivity in different organs (spleen, liver, and lungs) was reduced in mice with high natural killer (NK) cell reactivity in their spleens, as measured in vitro by concomitant short-term ⁵¹Cr release assay. Considerable parallelism between in vitro and in vivo reactivities against two mouse lymphomas and a human myeloid cell line was found in mice of different strains and ages. Similarly, various immunopharmacologic treatments had comparable effects on in vitro and in vivo reactivities. These findings are consistent with the hypothesis that rapid cytolysis of tumor cells occurred in vivo and that NK cells played a major role in their elimination. (19 refs)

- 79-7076 Myasthenia Gravis and Lymphoma. A Clinical and Immunological Association. (Eng) Davis, S. (Dept. Neurology, Royal Melbourne Hosp., Melbourne, Australia); Schumacher, M. J. *JAMA* 242(19): 2096-2097; 1979.

Myasthenia gravis (MG) developed in a 62-yr-old man 6 mo after radiotherapy (three doses of 3,552 rads, 3,500 rads, and 4,000 rads, respectively) for poorly differentiated nodular lymphoma. T-cell immunodeficiency, including profound T-cell lymphopenia, impaired delayed hypersensitivity responses, and failure of a thymus-dependent antibody response to *Salmonella adelaide* flagellin, was demonstrated after MG was diagnosed. It is concluded that when MG and lymphoma coexist, both may have been triggered by an immunological defect. (9 refs)

- 79-7077 Immunity as the Predominant Factor Determining Metastasis by Murine Lymphomas. (Eng) Davey, G. C. (Div. Tumour Immunology, Chester Beatty Res. Inst., Belmont, Sutton, Surrey, England); Currie, G. A.; Alexander, P. *Br J Cancer* 40(4): 590-596; 1979.

The metastatic behavior of the L5178E (non-M) lymphoma and a highly metastatic subline L51787ES (M) was studied in syngeneic DBA2 mice. The non-M tumor rarely metastasized in intact syngeneic mice but produced extensive and rapidly lethal metastases when implanted into irradiated recipients. The metastatic behavior of the M subline was unaffected by irradiation of the host. By conventional transplantation criteria, the non-M tumor was more immunogenic than the M subline. Both tumors,

however, produced similar responses in a lymph node wt-gain assay. Host-cell infiltration of the tumors growing sc was much greater in the non-M than the M, the infiltrating cells being Fc-receptor-positive and maturing into macrophages after 2 days in vitro. It was concluded that while spontaneous in vitro motility of the M cells is much greater than that of the non-M, the metastatic behavior of the tumors is clearly determined by host immunologic responses. (11 refs)

- 79-7078 Hypothesis: Non-Hodgkin Lymphomas are Abnormal Immune Responses. (Eng) Habeshaw, J. A. (I.C.R.F. Gordon Hamilton Fairley Lab., St. Bartholomew's Hosp., West Smithfield, London EC1A 7BE, England). *Cancer Immunol Immunother* 7(1): 37-42; 1979.

Lymph-node biopsies from 174 patients with a confirmed diagnosis of non-Hodgkin lymphoma (NHL) were examined. Cell suspensions made from the affected nodes were studied for expression of surface antigens by immunofluorescence with specific antisera. Surface immunoglobulin expression and presence of surface receptors were also assessed. Tumors of undifferentiated cells (lymphoblastic lymphoma), of which there were 16 cases, showed the phenotypes of stem cells in 4 cases and of human thymus-leukemia-associated antigen (HTLA)-positive T cells in 7 cases. Five cases of B lymphoblastic lymphoma showed origin from B cells early in the maturation sequence at the time of either the primary or pre-primary immune response. Fifty-four patients had lymphocytic lymphoma, which was often associated with chronic lymphocytic leukemia. Most of these tumors appeared to arise from pre-primary immune response B lymphocytes. Tumors derived from follicular cells (centroblastic, centrocytic, or mixed tumors) were studied in 72 patients. These tumors showed a mix of B cell phenotypes, of T cells associated with a monoclonal B-cell component, and of cells with null-cell phenotypes. Immunoblastic and plasmablastic tumors, and lymphoplasmacytoid tumors, also showed a mix of these phenotypes. It is therefore concluded that most cases of NHL in humans are derived from primary or preprimary immune response B lymphocytes (as in lymphocytic lymphoma), germinal center B cells with a T-cell-predominant phase, or post-follicular memory or proplasma cells which may be blast-transformed (as in immunoblastic lymphoma) or quiescent (as in lymphoplasmacytoid lymphoma). Surface markers show that in the majority of tumors, the "neoplastic" B cell population was derived from a clone undergoing antigen-driven expansion in a follicular or post-follicular immune reaction. It is proposed that NHL represents an abnormal immune response in which the proliferating cells become frozen in an attitude of proliferation by failing to terminate the response in the normal way. (48 refs)

- 79-7079 Teratocarcinoma Transplantation Rejection Loci: An H-2-linked Tumor Rejection Locus. (Eng) Siegler, E. L. (Johns Hopkins Sch. Medicine, Baltimore, MD 21218); Tick, N.; Teresky, A. K.; Rosenstrauss, M.; Levine, A. J. *Immunogenetics* 9(3): 207-220; 1979.

Teratocarcinoma 129/Sv was 100% transplantable in syngeneic 129/Sv mice, but did not form tumors in BALB/c, C3H/He, or C57BL/6 mice, even though 129/Sv stem cells do not express detectable H-2 antigens. This tumor was 100% transplantable in F₁ hybrids of 129/Sv mice with the other three strains. Backcross and F₂ mice segregated the BALB/c, C3H/He, and C57BL/6 tumor transplantation rejection loci in a way suggesting that each strain has one or two such loci. The teratocarcinoma transplantation re-

jection locus in BALB/c and C3H/He mice seemed to be on chromosome 17, eight to nine recombination units from the H-2 complex. C57BL/6 mice apparently had the 129/Sv tumor-accepting (sensitive) allele at the H-2-linked locus but rejected the tumor because of antigenic differences at a second locus. These major teratocarcinoma transplantation rejection loci determined tumor acceptance or rejection after inoculation of high doses of tumor tissue (750 µg tumor protein). A number of minor genetic factors apparently affected the efficacy of tumor rejection and caused complete tumor rejection at lower tumor doses (7.5-75 µg tumor protein). (32 refs)

- 79-7080 Enhancement of Experimental Tumors in Mice by Treatment with Concanavalin A. (Eng) Ekstedt, R. D. (Dept. Microbiology, Northwestern Univ. Medical Sch., 303 E. Chicago Ave., Chicago, IL 60611). *J Natl Cancer Inst* 63(4): 1065-1069; 1979.

To investigate the effect of lectins on tumor induction and development, weanling BALB/c mice received ip injections of 300 µg concanavalin A (Con A) prior to and at 48-hr intervals (3x/wk) after challenge with Moloney murine sarcoma virus (M-MuSV), 3-methylcholanthrene (MCA), or TEPC-15 plasmacytoma cells. These mice showed an enhancement of tumor induction or development. With the M-MuSV and MCA systems, this enhancement was evidenced by larger tumors and, in the MCA system, by more devastating tumors. M-MuSV-induced tumor regression was more prolonged in Con A-treated mice. In the TEPC-15 system, enhancement was evidenced by more rapid mortality in treated animals. (24 refs)

- 79-7081 Peritoneal Macrophages from Adjuvant Arthritic Rats Enhance Tumour Cell Growth In Vitro. (Eng) Binderup, L. (Dept. Pharmacology, Leo Pharmaceutical Products, DK-2750 Ballerup, Denmark); Bramm, E.; Arrigoni-Martelli, E. *Experientia* 35(9): 1230-1232; 1979.

The effects of peritoneal macrophages from rats with adjuvant arthritis (AA, a chronic inflammatory disease triggered by immunologic mechanisms) on the in vitro growth of two rat tumor cell lines, Yoshida sarcoma (YS) and ascites hepatoma AH-13, were studied. AA was induced in female Lewis rats by injection of heat-killed *Mycobacterium butyricum*. Macrophages from arthritic rats, but not those from normal control rats, consistently enhanced [³H]thymidine (TdR) incorporation into YS cells, the greatest enhancement being seen with 10⁶ cells/ml taken on day 21 after the induction of AA. All tumor cell cultures contained >90% viable cells after the addition of macrophages. Nonadherent host cells did not appear to interfere with the macrophage/tumor cell assay. Thus, macrophages from rats with AA appear to have a decreased ability to deal with tumor cells. It is suggested that the immunologic commitment of the macrophages could interfere with their regulation of tumor cell proliferation in vivo. (15 refs)

- 79-7082 Tumor-enhancing Suppressor Activator T Cells in Spleens and Thymuses of Tumor Immune Mice. (Eng) Hellstrom, I. (Div. Tumor Immunology, Fred Hutchinson Cancer Res. Center, Seattle, Washington 98104); Hellstrom, K. E.; Bernstien, I. D. *Proc Natl Acad Sci USA* 76(10): 5294-5298; 1979.

The role of suppressor T cells in tumor immunity was investigated by studying the effect of adoptively transferred syngeneic lymphoid cells on the growth of primary Moloney sarcoma virus (MSV)-induced sarcomas in BALB/c mice. Twenty-day-old BALB/c mice were inoculated with MSV and 1 or 6 days later were injected iv with cells from the thymus, spleen or lymph nodes of mice whose MSV-induced sarcomas had regressed 2-3 mo earlier. Thymus cells from normal BALB/c mice did not change the incidence of regression of primary MSV-induced sarcomas. Thymus and spleen cells from MSV regressors significantly decreased the extent to which primary MSV sarcomas regressed. A small tumor-enhancing effect was observed with the lymph node cells. The cells responsible for this tumor-enhancing effect carried the Thy 1 marker. They were not demonstrable in the thymuses of normal untreated mice or in mice immunized against or bearing methylcholanthrene (MCA)-induced sarcomas. The tumor-enhancing cells were not destroyed by administration of 400 rads of whole body radiation. The effect of the irradiated cells, however, was seen only in the presence of a normal nonirradiated T-cell population. Similar results were obtained with a transplantable MCA-induced, murine leukemia virus antigen-negative sarcoma, MCA-1460. These results support the concept that relatively radioresistant thymus cells from immune mice can enhance tumor outgrowth by interacting with radiosensitive T cells that are present in nonimmune mice. (15 refs)

- 79-7083 Studies on Metastases. I. Role of Sensitization and Immunosuppression. (Eng) Seshadri, M. (Medical Div. (RBOH), Bio-Medical Group, Bhabha Atomic Res. Center, Trombay, Bombay 400 085, India); Poduval, T. B.; Sundaram, K. *J Natl Cancer Inst* 63(5): 1205-1210; 1979.

Factors involved in the observed metastasis of normally nonmetastatic fibrosarcoma to the regional axillary lymph nodes following severe immunosuppression of inbred Swiss mice were investigated. The extent of metastasis was dependent on the severity of lymphocyte depletion and the initial number of tumor cells injected. Sensitization of the host to the tumor was important in prevention of metastasis: Metastasis was induced only if the immunosuppressive treatment occurred within 3 days of tumor inoculation. Antitumor immunity was adoptively transferred by the splenocytes from animals given immunosuppressive treatment with x-rays or hydrocortisone acetate on day 14. Though spleen cells from animals given both immunosuppressants did not have this property, the fact that no metastasis was observed even in doubly immunosuppressed mice indicated sensitization to tumor cells. Lymphocyte number was also important: Injection of splenocytes from normal animals to tumor-bearing mice significantly reduced the occurrence of metastases. (23 refs)

- 79-7084 Immunologic Abnormalities in Melanoma-prone Families. (Eng) Dean, J. H. (Immunobiology Section, Environmental Biology Branch, Natl. Inst. Environmental Health Science, Box 12233, Research Triangle Park, NC 27709); Greene, M. H.; Reimer, R. R.; LeSane, F. V.; McKeen, E. A.; Mulvihill, J. J.; Blattner, W. A.; Herberman, R. B.; Fraumeni, J. F. *J Natl Cancer Inst* 63(5): 1139-1145; 1979.

Extensive immunologic studies were carried out in 60 members of four families prone to cutaneous malignant melanoma (CMM) and a genetically determined precursor nevus syndrome. The most consistent finding was a diminished in vitro response to pooled alloantigens in one-way mixed leukocyte culture (MLC) and a tendency

toward low T-lymphocyte and B-lymphocyte levels. When compared with controls, low B-lymphocyte levels and reduced MLC responses were found not only in family members with CMM and/or precursor nevi but also in unaffected blood relatives and spouses. The genesis of the immune dysfunction and its possible relationship with melanoma pathogenesis remain to be clarified. (34 refs)

- 79-7085 Circulating Immune Complexes as Possible Cause for Anticomplementary Activity in Humans with Malignant Melanoma. (Eng) Gupta, R. K. (Div. Oncology, CHS 54-140, UCLA Sch. Medicine, Univ. California, Los Angeles, CA 90024); Theofilopoulos, A. N.; Dixon, F. J.; Morton, D. L. *Cancer Immunol Immunother* 6(4): 211-221; 1979.

Sera from 98 melanoma patients, 20 noncancer patients with immune complex-associated disease, and 90 normal donors were analyzed for anti-complementary (AC) activity by the complement consumption method. Some of these sera were also tested for immune complex-like materials by the Raji cell radioimmune assay. In addition, serum samples from 10 melanoma patients were analyzed serially to correlate the AC activity with clinical course. Significant levels of AC activity were found in 45% of melanoma sera, 75% of nonmalignant immune complex-associated disease sera, and 10% of normal donors' sera. In some patients, AC activity decreased until no longer detectable as their disease progressed. AC-negative serum samples taken from melanoma patients late in the course of disease when the tumor burden was large became AC-positive when mixed with autologous or allogeneic serum samples taken earlier at the time of little or no tumor burden. The early serum samples contained antibodies against autologous tumor extracts, as shown by a complement fixation test. Absorption of early serum samples with cultured allogeneic melanoma cells reduced their ability to consume complement when mixed with autologous late serum samples, suggesting the presence of free antigen in the latter. The mixed samples of early and late sera and the sera positive in the complement consumption test contained heavy nonmonomeric IgG. Therefore, the AC activity of melanoma sera could be due to tumor-associated antigen-antibody complexes. (49 refs)

- 79-7086 Immune Response to Melanoma Extracts in Three Melanoma-Prone Families. (Eng) Vandenbark, A. A. (Surgical Res. Lab., Veterans Admin. Medical Center, 3710 SW U.S. Veterans Hosp. Rd., Portland, OR 97207); Greene, M. H.; Burger, D. R.; Vetto, R. M.; Reimer, R. R. *J Natl Cancer Inst* 63(5): 1147-1151; 1979.

Immune reactivity to melanoma extracts was measured by the leukocyte adherence inhibition (LAI) test in 40 members of three melanoma-prone families. The melanoma patients had a wide range of responsiveness to the extract, the highest responder being a 10-yr survivor. As a group, family members (including spouses) without disease had significantly elevated LAI responses compared with those of unrelated controls ($p < 0.01$). Within the families, members with close exposure to melanoma patients for ≥ 10 yr had a significantly higher response to melanoma antigen than did members with 0-5 yr of close exposure ($p < 0.05$). Responses of spouses and members at high risk of developing melanoma (B-K mole syndrome) also correlated with length of exposure to patients, which suggests that the elevated LAI response was not genetically determined. The high frequency of positive responses to melanoma antigens in these families, particularly in spouses,

suggests the presence of transmissible melanoma-associated material capable of immunizing persons in contact with melanoma patients. (34 refs)

- 79-7087 In Vitro Lymphocyte Reactivity to Soluble Tumor Extracts in Sinclair Melanoma Swine. (Eng) Aultman, M. D. (Sinclair Comparative Medicine Res. Farm, R.D. 3, Columbia, MO 65201); Hook, R. R. *Int J Cancer* 24(5): 673-678; 1979.

An antigen-stimulated active rosette assay was adapted as an in vitro assay for the detection of lymphocyte reactivity to soluble tumor extracts. An increase in active rosette-forming cells (A-RFC) occurred only when sensitized lymphocytes from Sinclair melanoma swine were stimulated with specific sensitizing antigen. Lymphocytes from melanoma swine reacted in vitro to 3 M KCl extracts of autologous and allogeneic melanomas but did not react to 3 M KCl extracts of autologous and allogeneic swine skin. Lymphocyte reactivity to allogeneic melanoma extract (AME) was demonstrated by 84.8% of the melanoma swine, as compared to 23.5% of normal swine. The reactivity of the melanoma swine lymphocytes to AME was not due to reactivity of the lymphocytes to normal skin antigens or fetal swine antigens present in the AME. Lymphocytes from three melanoma swine increased A-RFC after incubation with each of nine different AME; thus the ability to stimulate lymphocyte reactivity was not limited to a single AME. The data indicate that a tumor-related immune response occurs in melanoma swine and that in vitro lymphocyte reactivity is directed towards a tumor-associated antigen or antigen-like substance present in 3 M KCl extracts of swine melanoma. - 79-7088 Solid Tumors Complicating Hodgkin's Disease: A Report on Two Patients with Immunoglobulin Deficiency. (Eng) O'Sullivan, D. D. (Div. Oncology/Hematology, Chicago Medical Sch., Chicago, IL 60664); Raghuprasad, P.; Ezdinli, E. Z. *Arch Intern Med* 139(10): 1131-1134; 1979.

The development of multiple epithelial malignant neoplasms following radiotherapy and intensive chemotherapy for Hodgkin's disease is reported in two patients. At the time of diagnosis of the second primary tumor, both patients had been in prolonged complete remission, and serum immunoglobulin deficiencies were detected. In one case, there was no detectable serum IgA on several occasions prior to the discovery of adenocarcinoma of the lung and kidney. In the second case, no secretory IgA was detected in the saliva, and some degree of serum IgA, IgG, and IgM deficiency was present. The second patient had well-differentiated squamous cell carcinomas of the perineum, vagina, and cervix uteri, each of which was a separate primary neoplasm. A literature review indicated that the incidence of nonhematological cancers in patients with Hodgkin's disease varies from 1.5% to 6.6%. The authors concluded that there is a fivefold increase in the incidence of solid tumors in Hodgkin's disease patients compared with the general population. (19 refs)

- 79-7089 Suppressor Adherent Phagocytic Cells in Solid Tumors: A Postulated Escape Mechanism. (Eng) Parks, R. C. (AMC Cancer Res. Center and Hosp., 6401 West Colfax Ave., Lakewood, CO 80214). *Med Hypotheses* 5(9): 1017-1023; 1979.

A localized graft-vs-host (GVH) reaction was used to assess the cellular immunity of BALB/c mice bearing the progressively growing allogeneic melanoma S91-TMS. Splenic lymphocytes from these mice were inoculated into the hind footpads of (BALB/c x DBA/1)F₁ mice, and the GVH reaction was measured in the popliteal lymph nodes. The growing tumor evoked a hyperactive cell-mediated immune response, and an adherent phagocytic cell (APC) population isolated from the tumor effectively inhibited this specific immunologic activity. An important factor in the successful growth of the immunogenic tumor thus appears to be a coterminous population of APC that has the functional capacity to specifically nullify, in situ, cell-mediated immunity directed against the neoplasm. It is suggested that the APC population may originate in response to homeostatic factors associated with tissue damage and change, thus benefitting primary and possibly secondary inchoate tumor development via the inhibition of immunologic recognition and rejection responses that the host generates against the neoplasm. (35 refs)

- 79-7090 Beta-Glucuronidase Deficiency in Neutrophils of Patients with Precancerous States of the Larynx. (Pol) Lisiewicz, J. (Klinika Laryngologii, Instytutu Chorob Układu Nerwowego i Narządów Zmysłowych, Śląskiej Akademii Medycznej, ul. Kopernika 17, 31-501 Krakow, Poland); Gierek, T.; Kusnierczyk, W.; Pilch, J. *Przegl Lek* 36(8): 609-611; 1979.

The β -glucuronidase (BG) and acid phosphatase (AP) activities of peripheral blood neutrophils were studied in 24 men with precancerous states of the larynx and in 20 healthy male controls by determining the enzyme-positive and enzyme-negative cell counts and the enzyme activity variations within the enzyme-positive cell population. No differences were found in the AP activities between the two groups. In contrast, the BG activity was significantly lower in the patients than in the controls. The most striking difference was the nearly complete absence of BG-positive neutrophils with high enzyme activity in the patients; the majority of their BG-positive cells showed only traces of enzyme activity. The BG deficiency is assumed to be due to the neutrophil-mediated cytotoxic effect against mammalian tumor cells. (12 refs)

- 79-7091 Human Lung Tumor-associated Antigens of 32,000 Daltons Molecular Weight. (Eng) Kempner, D. H. (Dept. Pediatric Hematology, Oncology, and Immunology, Cedars-Sinai Medical Center, Halper Bldg. Rm. 618, Los Angeles, CA 90048); Jay, M. R.; Stevens, R. H. *J Natl Cancer Inst* 63(5): 1121-1129; 1979.

Lung tumor-associated antigens of approx 32,000 daltons were recognized by the use of sensitive radioimmunoassays and rabbit antisera, one raised against an extract of pooled human malignant lung tissues and another raised against a cell line derived from a human squamous cell carcinoma of the lung. These antigens differed from antigens described previously, including carcinoembryonic antigen and α -fetoprotein. The antigens were detected on 13/13 lung tumors (of all histologic types), fetal tissue, normal brain, 2/8 colon tumors, 2/9 prostate tumors, and 2/3 breast tumors, as well as on cell lines derived from lung tumors, neuroblastoma, human amnion, colon adenocarcinoma, and bladder tumors. They were not detectable on normal lung, liver, kidney, colon, or prostate tissues or on cell lines derived from osteosarcoma, fetal lung fibroblasts, transitional cell carcinoma, and squamous cell carcinoma of the skin. Lung tumors of different histologic types were concluded to express common, tumor-

associated oncofetal antigens that are found less often in tumors of other organs. (44 refs)

- 79-7092 **Antigenic Expression on Mouse Hybrid Cells.** (Eng) Tachibana, T. (Dept. Immunology, Res. Inst. Tuberculosis and Cancer, Tohoku Univ., Seiryomachi 4-1, Sendai 980, Japan); Dei, T. *Gann Monogr Cancer Res* 23: 239-245; 1979.

The eclipse phenomenon of H-2 antigenic expression was studied in somatic cell hybrids formed between L cells and non-Ehrlich tumor cells. Suppression of the H-2 antigenic expression (ie, the eclipse phenomenon) similar to that previously seen in hybrids between L and Ehrlich cells was observed in hybrids between L cells and FM3A ascitic mammary tumor cells and between L cells and spontaneous mammary carcinoma (SMCA) cells. FM3A cells expressed mouse mammary tumor-specific surface antigen (MM antigen), which was lacking in the SMCA cells from which they were derived by serial passage through a syngeneic host. Both hybrid populations showed expression of the MM antigen with simultaneous reduction of the H-2 antigen expression. It is suggested that the suppression of the surface antigens of the partner is produced by mammary tumor cells (Ehrlich, FM3A, and SMCA). (14 refs)

- 79-7093 **Abrogation of the Phenomenon of Leukocyte Adherence Inhibition by Excess Circulating Tumor Antigen.** (Eng) Thomson, D. M. (Div. Clinical Immunology and Allergy, Montreal General Hosp. Res. Inst., McGill Univ., Montreal H3G 1A4, Canada); Tataryn, D. N.; Schwartz, R.; MacFarlane, J. K. *Eur J Cancer* 15(9): 1095-1106; 1979.

The patterns of peripheral blood leukocyte (PBL) nonadherence to glass were compared in a group of control subjects, a group of patients with localized colon and breast cancer, and another group with metastatic colon and breast cancer. When incubated with extracts of unrelated cancer, PBL from patients with localized cancer showed nonadherence equal to those of controls. When these same leukocytes were incubated with extracts of the sensitizing cancer, leukocyte nonadherence was significantly higher than in control subjects. The leukocytes from patients with metastatic cancer exhibited a high leukocyte nonadherence, whether they were incubated with specific (sensitizing cancer) or nonspecific tumor extracts. The leukocyte adherence inhibition (LAI) reactivity was abrogated by preincubation with the sensitizing tumor-specific antigen (TSA) either from solid tumor or isolated from serum. The tumor antigen coat on the leukocytes from metastatic cancer patients was removed by trypsinization of the leukocyte surface, which restored its capacity to react with the sensitizing tumor antigen. It is concluded that the nonadherence of leukocytes from patients with localized or metastatic cancer is induced by the immunologically specific binding of TSA to the monocyte's cell surface. In leukocytes from patients with localized cancer, this reaction takes place in vitro, whereas in those from patients with metastatic cancer, TSA binding occurs in vivo. (27 refs)

- 79-7094 **α_1 -Fetoprotein mRNA of Rat Yolk Sac and Hepatoma.** (Eng) Chiu, J. F. (Dept. Biochemistry, Univ. Vermont, Coll. Medicine, Burlington, VT 05405); Dechamphai, W.; Commer, P. *Nucleic Acids Res* 7(1): 239-249; 1979.

Rat yolk sac α -Fetoprotein (AFP) messenger RNA (mRNA) was purified and characterized. AFP mRNA was isolated and purified to apparent homogeneity by means of immunoadsorption and oligo (dT) cellulose affinity chromatography. Purified AFP mRNA migrated as a 21S peak in 2.5% sodium dodecyl sulfate (SDS) polyacrylamide gels. The translation product of this mRNA in micrococcal nuclease-treated reticulocyte lysate was identified as AFP by specific immunoprecipitation, SDS-gel electrophoresis and tryptic digestion analysis. DNA complementary to AFP mRNA was synthesized with avian myeloblastosis virus RNA-dependent DNA polymerase. This AFP complementary DNA was used as a probe to quantitate AFP mRNA in the developing rat liver and to compare the complexity and diversity of AFP mRNA derived from the normal rat liver and Morris hepatoma 7777. The amount of functional AFP mRNA decreased during liver development. There was little, if any, AFP mRNA in the adult rat liver. A high degree of homology between the AFP mRNA sequences of yolk sac and hepatoma was also found. (31 refs)

- 79-7095 **Further Studies of a Macrophage Chemotaxis Inhibitor (MCI) Produced by Neoplasms: Murine Tumors Free of Lactic Dehydrogenase Virus Produce MCI.** (Eng) Snyderman, R. (Lab. Immune Effector Function, Howard Hughes Medical Inst., Duke Univ. Medical Center, Durham, NC 27710); Cianciolo, G. J. *J Reticuloendothel Soc* 26(4): 453-458; 1979.

The possibility that contamination with lactic dehydrogenase virus (LDV) causes the biologic activity of a macrophage chemotaxis inhibitor (MCI) found in several murine tumors was investigated in mouse hepatoma 129. Serum containing LDV or the cell-free supernatant (CFS) or ultrafiltrate (MCI) from long-term, ascites-passaged hepatoma cells substantially inhibited macrophage accumulation in the peritoneal cavities of phytohemagglutinin-treated C3Heb/Fej mice. CFS, not MCI, contained infectious LDV. CFS prepared from two different solid tumors and CFS and MCI prepared from hepatoma 129 ascites cells were also free of infectious LDV but inhibited in vivo macrophage accumulation by 63%-79%. Urine taken from mice 8 days after the ip injection of 5×10^6 hepatoma ascites cells inhibited macrophage accumulation by 76%, whereas urine from age-matched controls yielded only 18% inhibition. The urine was free from infectious LDV. The release of MCI by neoplasms may protect developing tumors from immunologic destruction during early phases of their growth. (13 refs)

- 79-7096 **Identification of a Tumor-specific Antigen in the Insoluble Fraction of Human Nephroblastoma.** (Preliminary Communication). (Eng) Okada, S. (Dept. Pathophysiology, Cancer Res. Inst., Kanazawa Univ., Kanazawa 920, Japan); Itaya, K.; Kurata, Y. *Eur J Cancer* 15(9): 1085-1093; 1979.

Physicochemical characteristics of a nephroblastoma-specific antigen were studied following its isolation. The insoluble fraction of three nephroblastomas was solubilized using desoxycholate. The soluble product obtained from this treatment was partially purified by gel filtration and used to produce sera by immunization of guinea pigs. After appropriate absorption, the antisera were reactive in gel diffusion only with nephroblastoma fractions and with sera from three patients with nephroblastoma. No reactivity was observed with fractions of normal adult or fetal organs, with a variety of other tumor types (including renal cell carcinoma, transitional cell carcinoma, stomach adenocarcinoma, colon

adenocarcinoma, epidermoid carcinoma of the cervix, hepatoma, lymphosarcoma, and rhabdomyosarcoma), or with control sera from 30 patients with nonmalignant diseases. The antisera also failed to react with carcinoembryonic antigen, with α_1 -fetoprotein, or with fetuin. The antigen also appeared to be different from the previously detected antigens in nephroblastoma, such as W-antigen and Wilms' tumor-associated antigen. Preliminary physicochemical studies indicated that this soluble product is nearly homogeneous and that the specific antigen has a mol wt of 60,000. The presence of the nephroblastoma-specific antigen in three nephroblastomas and in sera of three patients with this tumor suggests that it is a common antigen within nephroblastomas. (26 refs)

- 79-7097 Autoimmune and Lymphoproliferative Disease in (B6- G_{ix} x 129) F_1 Mice: Relation to Naturally Occurring Antibodies Against Murine Leukemia Virus-related Cell Surface Antigens. (Eng) Obata, Y. (Memorial Sloan-Kettering Cancer Center, 1275 York Ave., New York, NY 10021); Tanaka, T.; Stockert, E.; Good, R. A. *Proc Natl Acad Sci USA* 76(10): 5289-5293; 1979.

The characteristics and incidences of diseases in G_{ix} * F_1 hybrid C57BL/6 mice were compared with those in G_{ix} * F_1 mice and with those in the two parental strains, B6- G_{ix} * and 129. Only the G_{ix} * F_1 mice produce natural antibodies to G_{ix} antigen, the type-specific determinant of the major envelope glycoprotein of murine leukemia virus (MuLV). After 14 mo of age G_{ix} * F_1 mice developed a pronounced diffuse glomerulonephritis similar to that seen in systemic lupus erythematosus in man. These lesions occurred in 29/77 G_{ix} * F_1 mice but not in G_{ix} * F_1 , B6- G_{ix} *, or 129 mice. Lymphoproliferative lesions were either reticulum cell sarcoma (RCS) type A or reactive lymphoid hyperplasia (RLH). RCS occurred in 29/77 G_{ix} * F_1 mice, as opposed to 4/33 G_{ix} * F_1 , 2/25 B6- G_{ix} * and 0/22 129 mice. RLH occurred in 8 G_{ix} * F_1 mice but not in the other strains. In addition to G_{ix} antibody, the G_{ix} * F_1 mice produced antibodies to G antigens related to xenotropic and to ecotropic MuLV's, natural thymocytotoxic autoantibody, and antinuclear antibodies were produced by G_{ix} * F_1 mice. However, these four antibodies were also found in the other strains. It is concluded that the chronic production of G_{ix} antibody may be necessary for the

development of severe glomerulonephritis and for the increased occurrence of lymphoproliferative diseases in G_{ix} * F_1 mice. (23 refs)

- 79-7098 HLA System and Testicular Germinative Tumours. (Eng) Majsky, A. (Inst. Hematology and Blood Transfusion, U nemocnice 1, 128 20 Prague, Czechoslovakia); Abrahamova, J.; Korinkova, P.; Bek, V. *Oncology* 36(5): 228-231; 1979.

The frequency of 23 HLA antigens of the A and B loci was compared in 62 patients with testicular germinative tumors (40 with seminomas and 22 with nonseminomas) and 301 healthy unrelated subjects. The frequencies of HLA-A3, A10, B14, B40, and Bw35 antigens were increased in the seminoma patients, while A2 and B15 were decreased. Only the increase in Bw35 was statistically significant, but after correction, the result was no longer significant. In the nonseminoma patients (10 embryonal carcinomas, 5 teratocarcinomas, and 7 mixed forms), the frequency of HLA-A10, B18, B40, and Bw21 antigens was increased, and the frequency of B8 and B17 was decreased. The only statistically significant increase was that of the A10 antigen, but after correction the result was not significant. The 5-yr survival rate was higher in nonseminoma patients who had no HLA-A2, A9, A10, Aw19, B5, B12, B13 and Bw21 antigens. (28 refs)

PATHOGENESIS

- 79-7099 The Karyotype of Meningioma. (Ger) Zankl, H. (Institut für Humangenetik, Universität Saarlandes, W. Germany). *Veroeff Pathol* 111: 86 pp.; 1979.

A cytogenetic study of 140 meningiomas was performed. All cells or at least one cell line showed a partial or total G-monosomy (monosomy 22) in 72% of the tumors. After chromosome 22, the chromosomes 1, 13-15, 18, and the sex chromosomes were lost most frequently. Uniform karyotype was found in about 50% of all tumors, while two or more cell lines were seen in the others. In many cases it was obvious that multiple lines had arisen from one stemline. The most frequent mosaic in the same tumor (24 cases) was composed of cells with normal and 22-monosomic karyotypes. Structural chromosome aberrations, occurring regularly in all mitoses or at least in one cell line, were observed in 32 tumors; in 10 of these, one chromosome 1 showed a structural aberration. The long arm of chromosome 22 was deleted in 5 cases, the remaining fragment resembling the Philadelphia chromosome. Breaks were seen in 17.5% of the mitoses. Chromosomes 1 and 2 were affected more frequently than expected, whereas chromosomes of the C group showed very few breaks. Dicentric chromosomes were found mostly in chromosomes of group F. The frequencies of breaks and dicentric chromosomes showed a reverse correlation to the grade of hypodiploidy in the tumor mitoses. Typical in vitro growth of the more hypodiploid tumors contrasted with that of the meningiomas with normal karyotype and with monosomy 22, which showed a similar proliferation under tissue culture conditions. Tumors infiltrating the skull and recurrent tumors often showed a higher degree of hypodiploidy or an atypical chromosome loss. In nearly all meningiomas localized in the convexity of the cerebrum, a higher degree of hypodiploidy was observed. With only a few exceptions, the tumors of the spinal canal showed a monosomy 22, whereas those of the basis encephali had mostly normal karyotypes. While the male:female ratio in the entire series was 3:2, meningiomas with a higher degree of hypodiploidy or atypical chromosome loss were found in women as often as in men; and 75% of the tumors with normal or 22-monosomic karyotype occurred in women. - 79-7100 Hereditary Retinoblastoma: Host Resistance and Age at Onset. (Eng) Matsunaga, E. (Dept. Human Genetics, Natl. Inst. Genetics, 411 Mishima, Shizuoka-ken, Japan). *J Natl Cancer Inst* 63(4): 933-939; 1979.

Age-specific incidence data from 244 bilateral and 31 unilateral cases of hereditary retinoblastoma were analyzed. In the bilateral cases, there was a high correlation between the age of the patient at diagnosis in one eye with that in the other, suggesting that age at onset is largely determined by host factors common to both eyes. The mean ages of all patients at diagnosis varied consistently with the parental phenotype, suggesting that inherited host resistance plays an important role in the latency period. (27 refs)

- 79-7101 Absence of Chromosome Breakage in Patients with Retinoblastoma. (Eng) Knight, L. A. (Div. Cytogenetics, Dept. Pathology, Toronto General Hosp. and Univ.

Toronto, Toronto, Canada); Gardner, H. A.; Gallie, B. L. *Hum Genet* 51(1): 73-78; 1979.

To investigate the role of chromosome fragility in retinoblastoma (RB), peripheral blood lymphocytes from 12 patients with RB and 12 matched controls were studied. The frequency of chromatid and isochromatid aberrations was 5.6% of 763 cells from the RB patients and 7.3% of 423 cells from the controls. The frequencies of gaps and breaks in the RB patients were 3.4% and 1.7%, respectively; the frequency of breaks and fragments and translocations was 2.3%. In controls, the corresponding frequencies were 5.5%, 1.2%, and 1.4%, respectively. The results in RB patients did not differ significantly from those in controls. In only one instance was the frequency of breaks greater in an RB patient than in his control, and no significant difference was found between a similarly treated twin brother with RB and his control. Thus, RB is not associated with a spontaneous increase in chromosome fragility. (7 refs)

- 79-7102 New Findings in the Chromosome 13 Long-Arm Deletion Syndrome and Retinoblastoma. (Eng) Weichselbaum, R. R. (Harvard Medical Sch., Peter Bent Brigham Hosp., Boston, MA); Zakov, Z. N.; Albert, D. M.; Friedman, A. H.; Nove, J.; Little, J. B. *Ophthalmology (Rochester)* 86(6): 1191-1198; 1979.

The case reports are presented of three patients with ocular abnormalities or retinoblastoma associated with deletion of the long arm of chromosome 13 (13q-). Two patients had colobomas of the choroid as well as optic nerve hypoplasia and retinal dysplasia, both confirmed histologically; the third patient had retinoblastoma. Fibroblast radiosensitivities were examined in patients with sporadic and familial retinoblastoma and in the three patients reported here. Fibroblasts from patients with hereditary retinoblastoma were more radiosensitive than those from patients with sporadic retinoblastoma. Fibroblasts from the two patients with 13q- but without retinoblastoma showed radiosensitivity comparable to that of normal controls, while the patient with chromosome deletion and retinoblastoma showed significantly greater radiosensitivity than the normal controls. Increased radiosensitivity in patients with hereditary retinoblastoma may suggest a defect in a molecular DNA repair process. (28 refs)

- 79-7103 Metastatic Squamous Cell Carcinoma of the Lip. Occurrence in Blacks with Discoid Lupus Erythematosus. (Eng) Martin, S. (Dept. Dermatology, Baylor Coll. Medicine, Houston, TX); Rosen, T.; Locker, E. *Arch Dermatol* 115(10): 1214; 1979.

The development of squamous cell carcinoma of the lip in two black patients with chronic discoid lupus erythematosus (DLE) of the face and lip is reported. A 62-yr-old man with a 14-yr history of DLE developed a well-differentiated squamous cell carcinoma on the right side of the upper lip followed 2 yr later by fatal adrenal, hepatic, and bone marrow metastases. A 54-yr-old man

with an 18-yr history of DLA developed a poorly differentiated squamous cell carcinoma of the entire lower lip. Lymphatic metastases were also found on both sides of the neck. Enhanced metastatic potential may be present when squamous cell carcinoma arises in DLE of the lips. (6 refs)

- 79-7104 Malignant Fibrous Histiocytoma Arising in a Patient with Multiple Neurofibromatosis: A Case Report and a Literature Review. (Eng) Johnson, P. S. (Div. Hematology-Oncology, Dept. Internal Medicine, Univ. Iowa, Iowa City, IA 52240); Katz, D. A.; Pester, J.; Penn, R. *J Surg Oncol* 12(2): 97-105; 1979.

The case is reported of a 56-yr-old man with the characteristic clinical and histologic features of multiple neurofibromatosis. The patient also had a malignant fibrous histiocytoma involving the right thigh with metastasis to the lung. A definite association between Von Recklinghausen's disease and various sarcomas (most commonly neurofibrosarcomas) of the peripheral nerves and the somatic soft tissues is well-known. This is apparently the first report in the literature of a malignant fibrous histiocytoma arising in a patient with multiple neurofibromatosis. The phenomenon of sarcomatous change in Von Recklinghausen's disease and the clinical and pathologic features of malignant fibrous histiocytoma are discussed. (37 refs)

- 79-7105 Non-Hodgkin's Lymphoma and Acute Myeloblastic Leukemia. A Report of 12 Cases and Review of the Literature. (Eng) Zarrabi, M. H. (Veterans Admin. Medical Center, Northport, NY 11768); Rosner, F.; Bennett, J. M. *Cancer* 44(3): 1070-1080; 1979.

Twelve cases of non-Hodgkin's lymphoma and acute myeloblastic leukemia or one of its variants are reported, and an additional 33 cases from the literature are reviewed. The mean interval between the diagnoses of lymphoma and acute leukemia is 5.2 yr. In five patients the two diseases occurred simultaneously or within 6 mo of each other. All but 10 of the 45 patients received radiation therapy for their lymphoma. Nine patients had either total nodal or total body irradiation or both. Eight patients received chemotherapy alone. No patient was untreated. Survival after the diagnosis of acute leukemia ranged from 3 days to 14 mo, with a median of 3 mo. Four patients achieved complete hematological remission following antileukemic therapy. Acute leukemia is estimated to occur in patients with non-Hodgkin's lymphoma in New York State with a 37-fold increased frequency over the expected number. Although such an increase over expected frequency may be attributed to the increased risk of a second neoplasm in patients with a primary tumor, it seems more likely that the acute leukemia may be related to the radiotherapy and/or chemotherapy administered to treat the lymphoma. However, late death from leukemia after chemotherapeutic or radiotherapeutic remission of advanced non-Hodgkin's lymphoma is preferable to morbidity and/or early death from untreated or inadequately treated lymphoma. (67 refs)

- 79-7106 The 5q- and Additional Chromosome Anomalies in Two Patients with Acute Myeloid Leukemia. (Eng) Petit, P. (Dept. Cytogenetics, CDH, Ch. D'Alsemberg 196, B-1180 Brussels, Belgium); Van den Berghe, H. *Ann Genet (Paris)* 22(2): 103-105; 1979.

Two elderly women with acute myelogenous leukemia were found, upon initial marrow and unstimulated blood examination, to have deletions of the long arm of chromosome number 5 (5q-) and other chromosome anomalies. An 83-yr-old patient with a modal chromosome number of 46 also had a terminal deletion of chromosome 12. An 81-yr-old patient had a modal chromosome number of 43; chromosomes 7, 12, and 18 were missing. In addition to the 5q-anomaly, there was an acrocentric marker consisting of chromosome 21 bearing translocations on its long arm of part of the long arms of chromosomes 7 and 12. In each patient, the same anomalies were present in bone marrow and blood cells. (9 refs)

- 79-7107 "Pre-B" Phenotypes in Blast Crisis of PH⁺ Positive CML: Evidence for a Pluripotential Stem Cell "Target". (Eng) Greaves, M. F. (Membrane Immunology Lab., Imperial Cancer Res. Fund, London, England); Verbi, W.; Reeves, B. R.; Hoffbrand, A. V.; Drysdale, H. C.; Jones, L.; Sacker, L. S.; Samarasingha, I. *Leuk Res* 3(4): 181-187, 189-191; 1979.

Six patients with Philadelphia chromosome (Ph⁺)-positive acute leukemia and 20 patients with chronic myeloid leukemia (CML) in blast crisis were tested with a panel of immunological, enzymatic, and histochemical markers and for the presence of cytoplasmic Ig-M as an indicator of the earliest detectable cells in the B cell lineage (pre-B cells). Routine blood preparations from all patients had >25% blast cells. Nineteen patients had the phenotype common (c) to acute lymphoblastic leukemia (ALL) which included the cALL gp100 membrane antigen and terminal deoxynucleotidyl transferase. Three of these 19 patients, all of whom had CML in blast crisis, had leukemic cells with a pre-B phenotype (staining with anti-IgM). In two cases, >75% of lymphoblasts contained cytoplasmic IgM, but no cell surface immunoglobulin was present. Two other patients with CML in blast crisis had 5% IgM-positive cells. These findings indicate that Ph⁺ with a typical translocation onto chromosome 9 can penetrate into the B cell lineage and that clonal evolution in CML can involve selective growth of cells with an apparent maturation arrest in the early B cell compartment. These data provide evidence for the existence of a common lymphoid-myeloid pluripotential stem cell in humans, which might be the target for the Ph⁺ alteration and leukemia initiation in at least some patients with CML. (32 refs)

- 79-7108 Chromosomes and Causation of Human Cancer and Leukemia. XXXIV. A Case of "Hypereosinophilic Syndrome" with Unusual Cytogenetic Findings in a Chloroma, Terminating in Blastic Transformation and CNS Leukemia. (Eng) Huang, C. S. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263); Gomez, G. A.; Kohno, S. I.; Sokal, J. E.; Sandberg, A. A. *Cancer* 44(4): 1284-1289; 1979.

The case report of a patient in whom the "hypereosinophilic syndrome" terminated in a frank leukemic condition with an extramedullary granulocytic sarcoma (chloroma) and leukemic CNS involvement is presented. The patient, a 46-yr-old white man, developed massive hepatosplenomegaly, a pleural effusion, leukocytosis, and a left parasternal mass following relatively symptom-free persistent hypereosinophilia for about 5 yr. Bone marrow aspiration and biopsy and peripheral blood differential showed eosinophilia and a shift to the left with immature cells. A high serum vitamin B₁₂ level and a leukocyte alkaline phosphatase score of 0 were found. Biopsy of the soft tissue mass revealed a

chloroma with a hyperdiploid karyotype (49,XY,+10,+15+19,3q-), whereas the bone marrow cells had a normal male karyotype. The patient responded temporarily to chemotherapy but eventually developed CNS leukemia and died in the blastic phase of the disease. It is possible that this case represents a variant of Ph⁺-negative chronic myelocytic leukemia to which the term "chronic eosinophilic leukemia" could be applied. (30 refs)

- 79-7109 Leukemia in a Black Child with Bloom's Syndrome. Somatic Recombination as a Possible Mechanism for Neoplasia. (Eng) Festa, R. S. (Div. Oncology, Children's Hosp. Philadelphia, 34th and Civic Center Blvd., Philadelphia, PA 19104); Meadows, A. T.; Boshes, R. A. *Cancer* 44(4): 1507-1510; 1979.

The case report of a 5-yr-old black child with Bloom's syndrome and acute lymphocytic leukemia (ALL) is presented. The patient's skin had adjacent areas of decreased and increased pigmentation similar to "twin-spots", a manifestation of somatic cell DNA recombination, seen in *Drosophila*. Their presence provides evidence that clones of cells in Bloom's syndrome have become homozygous for a particular gene. Somatic cell recombination is proposed as a mechanism to explain the increased incidence of neoplasms in Bloom's syndrome and supports the hypothesis that cancer may be a recessive disorder at the cellular level. (25 refs)

- 79-7110 Epidemiology of Nodular Paragranuloma (Hodgkin's Disease with Lymphocytic Predominance, Nodular). (Eng) Poppema, S. (Pathologisch-Anatomisch Laboratorium der Rijksuniversiteit, Oostersingel 63, NL-9713 EZ Groningen, Netherlands); Kaiserling, E.; Lennert, K. *J Cancer Res Clin Oncol* 95(1): 57-63; 1979.

The age and sex distribution and the localization of excised lymph nodes of 206 patients with a nodular variant of Hodgkin's disease with lymphocytic predominance, termed nodular paragranuloma, are presented and compared with data on other types of Hodgkin's disease. The age curve of nodular paragranuloma showed a peak in the fourth decade, which was clearly separated from the peak in the third decade exhibited by the nodular sclerosis type of Hodgkin's disease and from the peak in the sixth and seventh decades of the mixed cellularity type. The peak in the age curve of nodular paragranuloma resulted from the high frequency in men in the fourth decade; the female age curve had no peaks. The overall male-to-female ratio was 2.4:1. The age and sex distribution of diffuse paragranuloma was nearly identical to that of nodular paragranuloma, whereas the age and sex distribution for other lymphocytic predominance types resembled that of the mixed cellularity type. These data indicate that the lymphocytic predominance type of Hodgkin's disease is not a uniform group and support the view that paragranuloma is a separate entity. Differences in localization of excised lymph nodes among the various types of Hodgkin's disease were noted but were considered to be of little significance. (11 refs)

- 79-7111 Mycosis Fungoides and Hodgkin's Disease Occurring in the Same Patient: Report of Three Cases. (Eng) Chan, W. C. (Dept. Pathology, Univ. Chicago, 950 E. 59th St., Chicago, IL 60637); Griem, M. L.; Grozea, P. N.; Freel, R. J.; Variakojis, D. *Cancer* 44(4): 1408-1413; 1979.

The occurrence of the nodular sclerosing type of Hodgkin's Disease (HD) in three patients with typical mycosis fungoides (MF) is reported. All three patients had a long history (8-15 yr) of MF skin lesions. In two patients, a 62-yr-old white man and a 53-yr-old white man, the disease followed a steady progression from initial erythematous scaly lesions to the development of plaques, and, eventually, to skin tumors. The diagnosis of HD was made 2 yr after the diagnosis of MF on the basis of skin biopsies. In the third patient, a 46-yr-old black man, small erythematous papules gradually evolved into small plaques. The histological diagnoses of MF and HD were made simultaneously. It is possible that some of the previously described cases of MF reported to have transformed into HD could be examples of these two lymphomas occurring in the same patient. (28 refs)

- 79-7112 Fatal Lymphoma after Transplantation of Cultured Thymus in Children with Combined Immunodeficiency Disease. (Eng) Borzy, M. S. (Dept. Pediatrics, Univ. Wisconsin, Madison, WI); Hong, R.; Horowitz, S. D.; Gilbert, E.; Kaufman, D.; DeMendonca, W.; Oxelius, V. A.; Dictor, M.; Pachman, L. *N Engl J Med* 301(11): 565-568; 1979.

A fatal, widespread, polyclonal, B-cell immunoblastic lymphoproliferative disorder that developed in three children (a 1-yr-old boy, a 3-yr-old girl, and a 4-yr-old boy) with combined immunodeficiency shortly after intraabdominal transplantation of cultured thymus epithelium for immunoreconstitution is described. All three patients had surface immunoglobulin-bearing cells (15%-20%) in the peripheral blood before transplantation and polyclonally elevated immunoglobulins afterward. Abnormal immunoregulation was demonstrated in all patients before transplantation by a lack of Concanavalin A-induced suppressor-cell activity in mixed leukocyte culture; this persisted in two patients after transplantation. The transplant may have acted as a promoter through immunostimulation or production of promoter factors; excessive polyclonal B-cell proliferation may have resulted because of inadequate immunoregulatory mechanisms. On the basis of experience with 30 patients with various immunodeficiency diseases, the incidence of this complication is approx 10% (3/30). (28 refs)

- 79-7113 Granulocytic Sarcoma Preceding Acute Leukemia. A Report of Six Cases. (Eng) Krause, J. R. (Central Hematology, Presbyterian-Univ. Hosp., Pittsburgh, PA 15213). *Cancer* 44(3): 1017-1021; 1979.

A 16-yr-old boy presented with granulocytic sarcoma in a pericardial effusion following trauma and preceding acute myelogenous leukemia (AML) by 8 mo. At the time of original diagnosis, four bone marrow aspirations and needle biopsy specimens all showed a normocellular marrow; repeat blood counts were also normal. Eight mo later, blood and marrow counts indicative of AML were observed. A review of the surgical files of one hospital for a 20-yr period revealed five additional cases of granulocytic sarcoma preceding AML by 1.5 to 9 mo. When presenting in an extramedullary site, especially preceding peripheral blood and bone marrow manifestations of leukemia, a misdiagnosis of histiocytic lymphoma may result. Although these six cases represent a very small series, the most recent cases have shown induction/remission and survival characteristics like those of AML patients without granulocytic sarcoma. (22 refs)

- 79-7114 Primary Amyloidosis, Pure Red Cell Aplasia, and Kaposi's Sarcoma in a Single Patient. (Eng) Shimm,

D. S. (Dept. Medicine, Duke Univ. Medical Center, Durham, NC); Logue, G. L.; Rohlfing, M. B.; Gaede, J. T. *Cancer* 44(4): 1501-1503; 1979.

The occurrence of Kaposi's sarcoma, pure red cell aplasia, and primary amyloidosis in a 53-yr-old black man is reported. Immunologic abnormalities associated with abnormal B-cell function and humoral immunity included marrow plasmacytosis, antinuclear antibodies, heterogeneous hyperglobulinemia followed by a small IgG kappa paraprotein, and Bence Jones proteinuria. The patient was able to convert his PPD skin test, indicating that other T-cell functions were intact. The abnormalities in B-cell function were not global, since IgM and IgA levels were normal and he did not suffer from recurrent bacterial infections. This case represents an interesting conjunction of three diseases, all of which are associated with an abnormal immunologic state. (20 refs)

- 79-7115 Ultrastructure of Telangiectatic Osteosarcoma. (Eng) Roessner, A. (Inst. Pathology, Univ. Munster/Westf., Westring 17, D-4400 Munster, W. Germany); Hobik, H. P.; Immenkamp, M.; Grundmann, E. *J Cancer Res Clin Oncol* 95(2): 197-207; 1979.

The features observed in tissue samples from two telangiectatic osteosarcomas (TOS) examined by light and electron microscopy are described. Samples were obtained from the excised tumors of two boys (15 and 17 yr old); diagnosis of TOS was based on clinical, radiologic, and histologic features. The microscopic findings were similar for both patients. Light microscopy revealed that most tumor areas were composed of cystic spaces filled with clotted blood and segmented by thin septa. Solid areas where osteoid production was more pronounced were composed of densely-packed cells with irregularly shaped nuclei. Clusters of anaplastic tumor cells were sometimes noted. Electron microscopy revealed osteoblast-like tumor cells, spindle-shaped cells of fibroblastic origin, anaplastic-type tumor cells, and chondroblast-like tumor cells. Also observed were endothelial cells that were connected by tight intracellular junctions and that surrounded erythrocytes to form small capillaries. These endothelial cells contained pinocytotic vesicles, large numbers of fine fibrils, small amounts of granular and agranular endoplasmic reticulum, well developed Golgi bodies, and cytoplasmic organelles that resembled the rod-shaped inclusion bodies of the Weibel-Palade type. The characteristics of these cells indicated that they were angiosarcomatous components, suggesting that a multipotent mesenchymal cell with a capacity for differentiation to osteoblast-like, fibroblast-like, chondroblast-like, and angioblastic cells may be the cell of origin in TOS. (12 refs)

- 79-7116 Osteogenic Sarcoma in Siblings. (Eng) Colyer, R. A. (Dept. Orthopedic Surgery, Indiana Univ. Sch. Medicine, 1100 W. Michigan St., Indianapolis, IN 46223). *Johns Hopkins Med J* 145(3): 131-135; 1979.

A brother and sister with osteogenic sarcoma are described. The sister (aged 16 yr) presented with a 2-mo history of shoulder pain. The microscopic findings in a biopsy specimen were consistent with a diagnosis of osteogenic sarcoma, which agreed with the radiologic findings. Despite amputation and chemotherapy, pulmonary metastasis appeared, and the patient died following surgical removal of the metastasis and further chemotherapy. The brother presented with knee pain of 5-mo duration at 11 yr of age. Osteogenic sarcoma was diagnosed, but the family refused all

treatment and the patient died with pulmonary metastasis 8 mo later. A review of the literature revealed an additional 30 cases of osteogenic sarcoma in 13 families. Twenty-two involved siblings, two father-daughter pairs, and the rest were more distantly related. The evidence that genetic factors play an etiologic role in osteogenic sarcoma is substantial, but environmental factors may also be involved. (28 refs)

- 79-7117 Growth of Osteoid Osteoma Transplanted into Athymic Nude Mice. (Eng) Urist, M. R. (UCLA Bone Res. Lab., 1000 Veteran Ave. A3-34, Los Angeles, CA 90024); Lindholm, T. S.; Mirra, J. M.; Grant, T. T.; Finerman, G. A. *Clin Orthop* (141): 275-280; 1979.

An osteoid osteoma was excised from the neck of the femur of a 23-yr-old man and cut into four 1.5-mm³ fragments for immediate transplantation into muscle pouches of athymic nude mice. One fragment was devitalized by lyophilization prior to implantation. The viable tumor cell xenografts grew, differentiated into uncanceled osteoid, and retained the characteristics of the original tumor. The killed implants were resorbed, but both the surviving viable and nonviable tumor tissue induced the connective tissue cells of the mouse host bed to proliferate and differentiate into normal cartilage and calcified bone. The mouse new bone deposits were remodeled and colonized by bone marrow, a tissue not seen in osteoid osteomas. These observations suggest that the sclerotic bone shell characteristic of osteoid osteomas may represent an inductive reaction of host bed tissue to an osteoma cell product comparable to the bone morphogenetic protein produced by normal bone cells and transferred by normal bone matrix. (29 refs)

- 79-7118 Production of Mesenchymal Tumors in Nude Mice Using Ph¹ Negative "Fibroblasts" Obtained from a Ph¹ Positive CML Patient and Other Human Sources. (Eng) Wilson, F. D. (Radiobiology Lab., Sch. Veterinary Medicine, Univ. California, Davis, CA 95616); Greenberg, B. R.; Spangler, W. L.; Shifrine, M.; Gershwin, M. E.; Klein, A. K. In: *Hematopoietic Cell Differentiation. Proceedings of the ICN-UCLA 1978 Symposium on Molecular and Cellular Biology held in Keystone, CO, 10 March 1978*. Golde, D. W.; Cline, M. J.; Metcalf, D.; Fox, C. F., eds. (New York: Academic Press) Vol. 10, 504 pp.; 231-240; 1978.

The development of a model system for investigating the role of hematopoietic stromal elements in the regulation of hematopoiesis and in the pathogenesis of myelofibrosis is reviewed. The model involves the selection of fibroblastic adherent cells from human bone marrow samples and the subsequent inoculation of these cells into nude mice. The fibroblastic cells had normal karyotypes, whether they were isolated from a patient with Philadelphia chromosome (Ph¹)-positive chronic myelogenous leukemia (Ph¹ + CML), from a male patient who had received a bone marrow transplantation from his sister and so represented a male-female hematopoietic chimera, or from normal volunteers. Mesenchymal tumors resulted from the injection of fibroblastic elements using adherent cells from all three sources. The tumors were composed of cells with fibroblastic to reticuloendothelial morphology and were not observed for more than 1 wk. There were no morphological or behavioral differences among mesenchymal tumors produced with CML, chimeric, or normal human sources. The results of these studies suggest that the adherent populations forming in bone marrow are not related to hematopoietic stem cells and contain stromal cell capacities when transplanted in vivo regardless of their

in vitro morphologies. The results in the nude mice establish the feasibility of using the transplantation model for investigating the pathogenesis of myelofibrosis associated with myeloproliferative disorders. (22 refs)

- 79-7119 The Histogenesis of Small-Cell Bronchial Carcinoma. (Ger) Raikhlin, N. T. (Abt. Pathomorphologie der Geschwulste des Menschen, Onkologisches Forschungszentrum, Kaschirskoje Chaussee 6, 115478 Moscow, USSR); Warzok, R.; Smirnowa, E. A. *Zentralbl Allg Pathol* 123(3): 202-209; 1979.

Electron microscopy (EM) revealed both neurosecretory granules (NSG) and multilamellar bodies (MLB) in a lung tumor which had the typical appearance of a small-cell (ie, oat cell) carcinoma by light microscopy. The latter technique revealed an apparently homogeneous small-cell carcinoma with dense nuclei often toward one end of the cell. The finding of NSG, considered typical of small-cell carcinoma, and MLB, characteristic of adenocarcinomas of the lung, both in the same tumor cell suggests that these types of lung carcinomas can originate from one type of pluripotent cell. The tumor, found in an upper pulmonary lobe of a 52-yr-old woman, was immediately fixed in glutaraldehyde for EM study. Anaplastic cells with large nuclei and few organelles were found, as were relatively differentiated cells with numerous mitochondria, polysomes, and endoplasmic reticulum. Transition forms between these two cell types were identified. The intracytoplasmic lamellar bodies were osmiophilic. Some cells contained only NSG or MLB, but usually both were found in one and the same cell. (34 refs)

- 79-7120 Role of Tumor Thromboplastin in the Mode of Distribution of Metastatic Foci in the Lung. (Eng) Kohga, S. (Dept. Pathology, Kyushu Univ., Maidashi 3-1-1, Higashi-ku, Fukuoka 812, Japan); Tanaka, K. *Gann* 70(5): 615-619; 1979.

Experiments were carried out to determine the role of tumor thromboplastin and the distribution of metastatic lesions in the lung. Crude tumor cell extract from rat ascites hepatoma AH130 had a clotting time of 14 sec compared with 19.5 sec for normal rat brain extract. The iv injection of this tumor extract in male Donryu rats caused thrombus formation in the capillaries, arterioles, and arteries of the lungs of rats killed 3 min or 72 hr after injection. Groups of six rats each received 0.2 ml tumor extract or saline followed immediately by 1×10^7 AH130 tumor cells iv. The rats were killed 3 min, 24 hr, or 72 hr after inoculation. Rats injected with tumor cell extract followed by tumor cells also showed thrombus formation in the capillaries, arterioles, and lung arteries, while the rats sacrificed 3 min after saline or tumor cell injection revealed widespread small thrombus formation, mainly in the capillaries and arterioles. After 72 hr, the number of metastatic foci in the lungs of the group pretreated with tumor cell extract was less than that in the group pretreated with saline. The size of metastatic foci in the alveolar septa in both groups was alike, but there was metastasis formation in the larger pulmonary arteries in the group pretreated with tumor cell extract but not with saline. These large metastatic foci were composed of tumor cells and various amounts of fibrin thrombi. These results suggest that tumor thromboplastin may play a role in the mode of distribution of metastatic foci in the lung. (17 refs)

- 79-7121 Carcinoma Arising in the Wall of Congenital Bile Duct Cysts. (Eng) Todani, T. (Dept. Surgery, Okayama Univ. Medical Sch., 2-5-1 Shikatacho, Okayama City

700, Japan); Tabuchi, K.; Watanabe, Y.; Kobayashi, T. *Cancer* 44(3): 1134-1141; 1979.

Four cases of carcinoma arising in a choledochal cyst are presented, and an additional 59 cases are reviewed from the literature. Three of four patients (3 women, 1 man, 17-26 yr old) had histologically verified adenocarcinomas arising from choledochal cysts; the fourth patient's tumor was a squamous cell carcinoma. The three patients with adenocarcinomas also had liver metastases, while the squamous cell carcinoma had spread widely to the neighboring retroperitoneum. Among the 63 patients reviewed, the ages ranged from 15 to 73 yr, and 42 of them were under 36 yr of age; thus, the average was several decades younger than that seen in extrahepatic carcinoma patients without bile duct cyst involvement. The female:male ratio in the 63 cases was 2.5:1, in contrast to a male predominance usually seen in carcinoma without bile duct cysts. The series included 42 Japanese patients and 36 patients who had undergone various internal drainage procedures (choledochocystoduodenostomy in 19, choledochocystojejunostomy in 6, and bile duct drainage in 11). Even with primary excision of the cyst, carcinoma could still arise from the retained bile duct or from intrahepatic cysts. Nine cases have been reported of patients with bile duct cysts who developed carcinoma in the liver, pancreas, pancreatic duct, or bile duct; thus the presence of congenital bile duct cysts may predispose to carcinomas throughout the hepatobiliary system. (26 refs)

- 79-7122 Analysis of Chromosomal Proteins of Fractionated Chromatin from Rat Liver and Transplantable Hepatocellular Carcinomas. (Eng) Rodriguez, L. V. (Dept. Pathology, Section Experimental Pathology, Univ. Texas System Cancer Center, Houston, TX 77030); Klein, K. K.; Amoroso, M.; Becker, F. F. *Int J Cancer* 24(4): 490-497; 1979.

The chromosomal proteins from a number of transplantable hepatocellular carcinomas (THC) induced by N-acetylaminofluorene or analogues of fluorenylacamide and showing great variations in growth rate were examined by sodium dodecyl sulfate polyacrylamide gel electrophoresis. Chromatin from hepatomas and from normal and regenerating livers of male Buffalo rats were fractionated into rapidly and slowly sedimenting gradient components. Ten nonhistone chromosomal proteins (NHCP) present in the tumors and ranging in mol wt from 220,000 to 55,000 were absent from normal liver. Also, each rapidly growing tumor possessed more nonhistone protein bands in the most rapidly sedimenting chromatin fractions than did the corresponding slowly growing tumor fractions. A number of single proteins common only to normal liver and/or rapidly or slowly growing tumors were also found. In contrast, NHCP banding patterns of rapidly growing 70% hepatectomized rat liver were identical to those of nondividing liver. The prototypic "minimal deviation tumor" (9618A) varied more in its NHCP-banding pattern when compared to liver than did rapidly growing, poorly differentiated tumors. (41 refs)

- 79-7123 Sequential Analysis of Hepatic Carcinogenesis: The Comparative Architecture of Preneoplastic, Malignant, Prenatal, Postnatal and Regenerating Liver. (Eng) Ogawa, K. (Dept. Pathology, Univ. Toronto, Toronto, Ontario, Canada, M5G 1L5); Medline, A.; Farber, E. *Br J Cancer* 40(5): 783-791; 1979.

The structural patterns of hepatocytes in early and late preneoplastic foci and nodules were compared with those in hepatocarcinomas, developing fetal and neonatal liver, and

regenerating liver. Hepatocytes were obtained from male Fischer-344 rats in which hyperplastic lesions were induced by diethylnitrosamine (200 mg/kg, ip) followed 2 wk later by 2-acetylaminofluorene (0.02% of the diet for 2 wk). The hepatocytes in hyperplastic lesions were arranged in plates two or more cells thick and in glands. They showed unusual separation from each other, with irregularly dilated bile canaliculi. Hepatocytes from normal adult liver were arranged only in one-cell-thick plates. The organizational pattern in the hyperplastic lesions resembled that in developing liver in the perinatal period, that in regenerating liver following the peak of cell division, and that in some hepatocellular carcinomas. However, the resemblance to developing and regenerating liver was incomplete, failing to reproduce exactly the characteristics of the normal tissues. Unlike the normal tissues, in which there was a highly predictable time scale for change, an apparent delay or interruption in maturation was observed in the hyperplastic lesions. This delay or interruption may be of importance in lesions that persist and ultimately evolve into hepatocellular carcinomas. (21 refs)

- 79-7124 Familial Islet Cell Tumors in Von Hippel-Lindau's Disease. (Eng) Hull, M. T. (Dept. Pathology, Indiana Univ. Sch. Medicine, 1100 W. Michigan, Indianapolis, IN 46202); Warfel, K. A.; Muller, J.; Higgins, J. T. *Cancer* 44(4): 1523-1526; 1979.

A family with well-documented Von Hippel-Lindau disease in four siblings, all of whom developed neoplasms, is reported. Three had cerebellar hemangioblastomas, two had retinal hemangioblastomas, and all four had pheochromocytomas; all of these neoplasms are characteristic of the disease. Additionally, two patients developed islet cell tumors of the pancreas, one in one patient and five in the other. Although a familial incidence of islet cell tumors is known in multiple endocrine adenomatosis, type 1 and Zollinger-Ellison syndrome, such a familial occurrence has been heretofore unrecorded in the Von Hippel-Lindau complex. (26 refs)

- 79-7125 The Fine Structure of Pancreatic Duct Neoplasm in Syrian Golden Hamsters. (Eng) Althoff, J. (Abteilung für Experimentelle Pathologie, Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover 61, W. Germany); Wilson, R. B.; Ogrowsky, D.; Pour, P. *Prog Exp Tumor Res* 24: 397-405; 1979.

Scanning and transmission electron microscopic observations of pancreatic neoplasm initiated or promoted by bis(2-hydroxypropyl)-N-nitrosamine (BHP), bis(2-acetoxypropyl)-N-nitrosamine (BAP), bis(2-oxopropyl)-N-nitrosamine (BOP), and N-nitroso-2,6-dimethylmorpholine (DMNM) in Syrian Golden Hamsters are presented. The main structural pattern of the pancreas is observed in fetal hamsters 3 days before delivery; within 4 wk of delivery, the acini grow to their normal size (38 x 27 µm). After treatment with nitroso compounds, acinar cell necrosis was seen in some cases, and other acini showed irregular formation of zymogen granules and an expanded rough endoplasmic reticulum. Mature islets of Langerhans (IL) are first observed 10 days after birth and enlarge throughout the following year. After treatment with nitroso compounds, the IL proliferated into small cystic channels lined with ductular epithelium; ductal and islet cells were connected by desmosomes. Periinsular duct formation also occurred. The lesions sometimes increased in size, compressing the remaining tissues and causing them to atrophy. Some cells exhibited

a single, centrally located cilium. The neoplastic foci underwent further alterations, such as ductular cuboidal and ductal columnar differentiation and atypia. Multifocal hyperplasia and proliferation of the ductular epithelium were observed concurrently with intra- and periinsular duct formation; this resulted in the development of an adenomatous pattern and the formation of benign adenomas surrounded by true and pseudocapsules. The luminal spaces were either lined by cuboidal single ciliated cells, columnar cells, or mixed-cell populations. The large ducts often showed hyperplastic epithelia as well as goblet cell metaplasia as early as 8 wk after initiation of treatment. A few weeks later, intraluminal proliferation showing papillary patterns and gland formation, eventually filling the lumen (dysplasia, carcinoma in situ, intraductal carcinoma) were observed. (8 refs)

- 79-7126 Aniridia-Wilms' Tumor Association: Evidence for Specific Deletion of 11p13. (Eng) Francke, U. (Dept. Human Genetics, Yale Univ. Sch. Medicine, New Haven, CT 06510); Holmes, L. B.; Atkins, L.; Riccardi, V. M. *Cytogenet Cell Genet* 24(3): 185-192; 1979.

The chromosomes of a 7-yr-old boy with aniridia, Wilms' tumor (WT), and mental retardation, previously reported as having an interstitial deletion of the short arm of chromosome 8 resulting from a t(8p+;11q-) translocation, were restudied with high-resolution trypsin-Giemsa banding of prometaphase chromosomes. The results revealed a complex rearrangement with four break points in 8p, 11p, and 11q, leading to a net loss of an interstitial segment of 11p, (region p1407 → p1304) but not of 8p. The patient's RBCs contained normal glutathione reductase (gene on 8p) and lactate dehydrogenase A (gene on 11p12) activities, indicating a gene dosage consistent with the chromosomal findings. The revised interpretation of this case agrees with those in seven others reported as having aniridia and interstitial 11p deletions. The data suggest that the distal half of band 11p13 is the site of gene(s) that lead to aniridia and predispose to WT and, to an even greater extent, mental retardation in the hemizygous state. (18 refs)

- 79-7127 Hereditary Renal-Cell Carcinoma Associated with a Chromosomal Translocation. (Eng) Cohen, A. J. (Dept. Renal Medicine, Univ. Massachusetts Medical Center, 55 Lake Ave. N., Worcester, MA 01605); Li, F. P.; Berg, S.; Marchetto, D. J.; Tsai, S.; Jacobs, S. C.; Brown, R. S. *N Engl J Med* 301(11): 592-595; 1979.

A family with renal-cell carcinoma and a constitutional chromosomal translocation is described. The cancer arose in five men and five women in three consecutive generations. The cancers produced symptoms in the proband and six relatives and was diagnosed in the three other relatives during screening of asymptomatic family members. The cancers tended to develop at earlier ages and to occur bilaterally and at several renal sites more frequently than do nonfamilial renal cancers. Karyotypes of the peripheral WBC of 22 adult family members showed that 10 had a balanced reciprocal translocation between chromosomes 3 and 8: 46 XY (or XX), t(3;8) (p21;q24). The other 12 subjects had normal karyotypes. The translocation was detected in all five family members who survived renal cancer and was assigned by pedigree analysis to three of the five who died from the disease. No family member with renal cancer had a normal karyotype. These findings provide karyotypic evidence that an inherited genetic abnormality predisposes humans to the development of a hereditary neoplasm. (21 refs)

- 79-7128 Prognostic Value of the Degree of Maturity and Histogenesis of Cancer of the Stomach. (Rus) Diksh-tein, E. A. (Dept. Pathologic Anatomy, M. Gorky Medical Inst., Donetsk, USSR); Vasilenko, I. V.; Shevchenko, N. I.; Merezko, V. A. *Arkhh Patol* 41(7): 25-32; 1979.

To evaluate the prognostic value of the degree of morphological differentiation, 110 specimens of stomach cancer were subjected to histological and histochemical examination. There were 46 specimens of adenocarcinoma and 64 specimens of poorly differentiated polymorphic cell or signet-ring cell carcinoma. Characteristic features of the poorly differentiated carcinomas were marked secretion of mucus and high activity of acid phosphatase, succinate dehydrogenase, and NAD-dependent malate dehydrogenase. In contrast, the adenocarcinoma cells showed high activity of NADP-dependent enzymes and less pronounced secretion of mucus. The results suggested a lower degree of cell differentiation (as opposed to histologic differentiation) and higher proliferative activity in the adenocarcinomas than in the undifferentiated carcinomas. The prognostic implications of the differences in cell and tissue differentiation between adenocarcinomas and undifferentiated carcinoma are discussed. (16 refs)

- 79-7129 Histogenesis of Carcinoma in the Glandular Stomach of the Rat After B I Resection. (Eng) Schlake, W. (Pathologisches Institut, Universität, Westring 17, 4400 Münster, W. Germany); Nomura, K. *Curr Top Pathol* 67: 1-67; 1979.

The histogenesis of carcinomas in the resected stomach was studied in Wistar rats subjected to gastric resection with subsequent Billroth-I gastroduodenostomy (OP) and treatment with N-methyl-N'-nitro-N-nitrosoguanidine (MNNG) in the drinking water and/or antilymphocyte globulin. Carcinomas developed by week 104 in the animals subjected to OP only, by week 50 in animals subjected to OP and given MNNG starting 6 wk after surgery, and by week 104 in the animals subjected to OP and given MNNG starting 1 yr after surgery. Carcinoma development in the anastomosed mucosa followed two pathways: one via adenomatous polyps to fully developed polypous carcinoma; and the other via adenocystic gland proliferation to serosa-oriented, endophytic carcinoma. Changes in enzyme localization and activity occurred in preneoplastic and neoplastic tissues and also in areas of benign glandular regeneration. Chronic atrophic gastritis was constantly associated with all anastomosed mucosal tissues. Prolonged alterations such as enhanced proliferation and massive shifting or displacement of proliferative zones were found in the anastomosed mucosa as a result of severe imbalances in the interactions between differentiation and proliferation. These alterations appeared to be important pathogenic factors in the development of carcinomas in the resected stomach. The results illustrate the risk involved in Billroth-I surgery and the necessity for minimizing or preventing conditions predisposing to malignant transformation. (165 refs)

- 79-7130 Peutz-Jeghers Syndrome with Intestinal Carcinoma: Report of the Association in One Family. (Eng) Hsu, S. D. (Dept. Medicine, Div. Hematology-Oncology, Univ. Texas

Medical Branch, Galveston, TX); Zaharopoulos, P.; May, J. T.; Costanzi, J. J. *Cancer* 44(4): 1527-1532; 1979.

The occurrence of intestinal carcinoma in a 38-yr-old man and his father, both of whom had Peutz-Jeghers syndrome (PJS), is reported. The son had a grade III infiltrative rectosigmoid adenocarcinoma with widespread local extension to the pelvic organs and metastases to the peritoneum, liver, and lungs. Five elongated pedunculated smooth-surface polyps with the classical features of PJS hamartomas were also found in the ileum and transverse colon. While undergoing the 7th of 16 abdominal operations for removal of gastrointestinal polyps at the age of 49 yr, the father was found to have a large sessile polypoid carcinoma at the splenic flexure. Since PJS is inherited as an autosomal dominant trait, the detection of gastrointestinal malignancy in an affected individual might indicate that other family members with PJS might be at high risk for the development of gastrointestinal cancer. (12 refs)

- 79-7131 Spontaneous Adenocarcinoma of Gastrointestine in Rats. (Jpn) Miyamoto, M. (Dept. Pathology, Osaka Univ. Medical Sch., Osaka, Japan); Mizumoto, S.; Maeura, Y.; Utsunomiya, T.; Hashimoto, Z.; Tsujimura, T.; Tadokoro, T.; Takizawa, S. *Gan No Rinsho* 25(13): 1316-1319; 1979.

The occurrence of spontaneous gastrointestinal adenocarcinomas in inbred Wistar-Furth (WF) and MM rats is reported. Among 18th generation WF rats tumors were found in the ascending colon of 9 animals (5 males, 4 females), in the stomach of 5 (3 male, 2 female), and in the small intestines of 3 (1 male, 2 female). Tumors developed at all three sites in one 4-mo-old WF female. The colon cancers were more advanced than the gastric and small intestine tumors. The gastric tumors were characterized by thickening of the pyloric area and associated nodular eruptions, with occasional ulceration of the body of the stomach itself. Combined gastric and ileocolonic cancer was also observed in two 3-mo-old MM females of generations 1 and 4. Among 3-mo-old rats, ileocolonic tumors developed in two MM females of generations 2 and 3, a WF male and a WF female of generation 18, and one of the latter's female progeny. Colorectal tumors were seen in a 3-mo-old MM male of generation 0, a 10-mo-old MM female of generation 2, and a 4-mo-old inbred WF female. (6 refs)

- 79-7132 Familial Factors in Bladder Carcinoma. (Eng) Lynch, H. T. (Dept. Preventive Medicine/Public Health, Creighton Univ. Sch. Medicine, Omaha, NE); Walzak, M. P.; Fried, R.; Domina, A. H.; Lynch, J. F. *J Urol* 122(4): 458-461; 1979.

Studies on two families showing an excess of carcinoma of the bladder are reported. Cancer was manifested in five generations of the first family: carcinoma of the breast occurred in the proband's paternal grandmother and paternal great-grandmother; transitional cell carcinoma of the bladder occurred in the proband at 52 yr of age; transitional cell carcinoma of the renal pelvis occurred at age 62 in the proband's paternal uncle; and the daughter of the proband died of neuroblastoma at age 4 yr. In the second family the proband's father had verified carcinoma of the colon and the proband and two siblings suffered from transitional cell carcinoma

of the bladder and/or renal pelvis. One of the siblings developed transitional cell carcinoma of the bladder at 24 yr of age and also had multiple sclerosis, as did one brother not affected by cancer. In neither family were there consistent occupational exposures, but there was an excess of cigarette smoking among at least some of the individuals affected by cancer. It is proposed that the etiology of familial bladder cancer may be complex, possibly involving other associated malignant neoplasms and/or certain non-neoplastic disorders in addition to specific carcinogen exposures. (21 refs)

- 79-7133 **Familial Ovarian Cancer.** (Eng) Lurain, J. R. (Dept. Gynecologic Oncology, Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY 14263); Piver, M. S. *Gynecol Oncol* 8(2): 185-192; 1979.

The occurrence of epithelial ovarian cancer in a mother, three of her five daughters, and one of her eight granddaughters is reported. Adenocarcinoma of the ovary was histologically confirmed in all but the mother as poorly differentiated papillary adenocarcinoma (2), poorly differentiated adenocarcinoma (1), and moderately differentiated endometrioid adenocarcinoma (1). Age at diagnosis was 33-51 yr (mean 42 yr). Three of the five women are alive 6, 5, and 2 yr after diagnosis, two without evidence of disease. All patients were parous, and there were no known predisposing disorders. This report brings to 27 the number of families recorded with multiple cases of epithelial ovarian cancer. In most cases, the age of onset of ovarian cancer is lower than in nonfamilial cases. The tumors do not appear to differ clinically or histologically from sporadically arising tumors. The prognosis in these families is generally unfavorable; of 92 women for which follow-up data is available, only 8 are now alive, 5 for <3 yr, 1 for 5 yr, 1 for 6 yr, and 1 for an unknown length of time. The pattern of familial occurrence suggests autosomal dominant inheritance. Prophylactic oophorectomy appears to be indicated in women in these ovarian cancer families, but it can probably be safely postponed until after the childbearing years. (27 refs)

- 79-7134 **Investigation of a Family Suspected of Being at High Risk for Cancer.** (Eng) Elwood, J. M. (Div. Epidemiology, Cancer Control Agency British Columbia, 700-686 West Broadway, Vancouver, BC V5Z 1G1, Canada); Crawford, G. M.; Werner, M. *Can Med Assoc J* 121(5): 559-563; 1979.

The family of a 46-yr-old woman with bilateral breast cancer was investigated as a suspected high-risk family for cancer. Interviews and review of hospital records and death certificates provided information for 199 family members, 19 of whom had cancer. In generation I, 1/3 women surviving infancy and 5/8 men died of cancer. In generation II, the patient's mother and aunt both had breast cancer. Among the 14 women in this generation, 5 had cancer (2 of the breast and 3 of the ovary); there was one cancer, a lymphoma, among the 15 men. The expected numbers were 1.24 and 1.16, respectively. The excess number in the women was statistically significant. In generation III, apart from the index patient, there was one woman with cervical cancer and two men with cancer. The excess was not significant. Only 1/83 members of the fourth generation had cancer, but most members were under 15 yr old. Although there was an increased incidence of cancer in the

women in the second generation, striking excesses were not seen in the next generation and there was no indication of a clear Mendelian pattern. (29 refs)

- 79-7135 **Tumor Phylloides of the Breast.** (Pol) Przysasz, T. (I. Klinika Chirurgiczna, Instytutu Chirurgii Centrum Kształcenia Podyplomowego WAM, ul. Szaserow 128, 00-909 Warsaw, Poland); Badowski, A. *Wiad Lek* 32(14): 971-975; 1979.

Tumor phylloides were diagnosed in four women in a series of 1,304 women operated for breast tumors during a 10-yr period. The four women were aged 37-51 yr (av 43.5 yr), and all had had at least one childbirth and had breastfed their babies. The tumor was unilateral in all cases, being located in the left breast or right breast in 2 cases each. The tumors were hard and fairly large (7-15 cm, av 11 cm). They showed a typical biphasic growth; the length of the first growth phase was 7-12 yr; that of the second phase, 4-24 mo. All four tumors developed from intracanalicular fibroadenomas. Malignant transformation or recurrence after excision was not seen. The findings are in agreement with data in the literature. (8 refs)

- 79-7136 **Noninvasive Precursor Lesions of Adenocarcinoma and Mixed Adenosquamous Carcinoma of the Cervix Uteri.** (Eng) Christopherson, W. M. (Dept. Pathology, Univ. Louisville Sch. Medicine, P.O. Box 35260, Louisville, KY 40232); Nealon, N.; Gray, L. A. *Cancer* 44(3): 975-983; 1979.

In an attempt to establish incidence rates for in situ carcinoma of the cervix in which adenocarcinoma was either the only or a major component, 4,350 cases of cervical carcinoma reported to a uterine tumor registry during 1953-1975 were reviewed. The records of all patients with the diagnosis of adenocarcinoma in situ (AIS) or of squamous carcinoma in situ (CIS) plus AIS were examined, and 16 patients from this group were identified as having noninvasive cervical carcinoma. Four cases of AIS with microinvasion were also diagnosed, two having pure AIS and two having AIS in combination with CIS. Nine of the 16 patients had the combined form, and 7 had AIS only. The incidence rates, calculated per 100,000 women aged 20 yr and older, were 36.9 for invasive squamous carcinoma of the cervix, 49.0 for CIS, 2.5 for invasive adenocarcinoma, and 0.21 for AIS. It is suggested that the greater frequency of squamous carcinoma of the cervix could be explained by the ubiquity of squamous metaplasia in the highly sensitive transformation zone of women of the childbearing age. The lower than expected incidence found for AIS or combined AIS-CIS may be partly explained by the location of these lesions in the endocervix, an area less accessible to cytologic detection. It is postulated that squamous cell carcinoma, adenocarcinoma, and mixed adenosquamous cell carcinoma of the uterine cervix all have a common cell origin in the subcolumnar reserve cell. (33 refs)

- 79-7137 **Development of Leydig Cell Tumors and Onset of Changes in the Reproductive and Endocrine Systems of Aging F344 Rats.** (Eng) Turek, F. W. (Dept. Biological

Sciences, Northwestern Univ., Evanston, IL 60201); Desjardins, C. *J Natl Cancer Inst* 63(4): 969-975; 1979.

Reproductive and endocrine system changes associated with the age-dependent onset of spontaneous testicular interstitial cell tumors were examined in male F344 rats. Histological examination of testes established that nodular interstitial cell hyperplasia was evident in three of five 12-mo-old rats and in all of five rats at 15, 18, 21, and 24 mo of age. Involution of the seminiferous epithelium was evident in all testes exhibiting extensive interstitial cell proliferation. Striking increments in serum prolactin and estradiol levels were noted with advancing age, whereas serum levels of follicle-stimulating hormone were unequivocally lower at 21 and 24 mo than at 6 mo of age. No measurable changes were detected in serum testosterone concentrations between 6 and 18 mo of age, but marked increments in this androgen, without any measurable change in circulating luteinizing hormone titers, were apparent in 21- and 24-mo-old rats. These findings point to a dynamic relationship between testicular interstitial cell tumorigenesis and age-related changes in the synthesis and/or secretion of gonadal and adenohipophyseal hormones. - 79-7138 Lung Cancer Affecting Persons Under Forty. (Cze) Pesek, M. (Klinika tuberkulozy a respiracnych nemoci, LF KU, Sokolovska 52, 323 11 Plzen, Czechoslovakia); Houdek, J.; Simeckova, B. *Stud Pneumol Phtiseol Cech* 39(3/4): 200-203; 1979.

Lung cancer was diagnosed in a series of 2,100 patients (1,949 men and 151 women, male:female ratio 13:1) during a 22 yr period, and the 66 patients (51 men and 11 women, male:female ratio 5:1) aged under 40 yr were studied. Small-cell carcinoma was diagnosed in 21 men and 1 woman, epidermoid carcinoma in 21 men and 2 women, columnar-cell carcinoma in 11 men and 5 women, mixed tumor in 1 man, alveolar-cell carcinoma in 1 man and 1 woman, and polymorphocellular carcinoma in 4 men; the histological type was not established in 7 men and 2 women. Three men were under the age of 25 yr, 21 men and 2 women were in the age bracket 26-35 yr, and 27 men and 9 women were in the age bracket 36-40 yr. The distribution of the histological types in the women under 40 yr of age was similar to that found in all 151 women. Among the 51 men, 80.3% were smokers, whereas among the (11) women 72.7% were nonsmokers. The relationship between smoking and histological type is discussed. (13 refs)

- 79-7139 Hashimoto's Thyroiditis: A Possible Risk Factor for Lung Cancer Among Japanese Women. (Eng) Yamashita, N. (Dept. Neurophysiology, Inst. Brain Res., Faculty Medicine, Univ. Tokyo, Tokyo 113, Japan); Maruchi, N.; Mori, W. *Cancer Lett* 7(1): 9-13; 1979.

The association between Hashimoto's thyroiditis (HT) and malignancy was studied based on the Tokyo University Hospital autopsy reports of 1,896 women aged ≥ 20 yr. Of these patients, 29 had confirmed HT and 78 had probable HT. The number of breast cancers among the 107 confirmed and probable HT patients was 8, compared with 4.52 expected; the difference was not statistically significant. There were significantly more lung cancers (11 cases) in the HT group than expected (5.26 cases) ($p < 0.05$), but there was no inclination toward any particular histologic type of lung cancer in this group. Compared with the controls without HT, the HT patients with lung cancer showed no significant differences in cigarette smoking or history of radiation therapy. The findings suggest that HT and related changes could be one of the risk factors for lung cancer among Japanese women. (4 refs)

- 79-7140 History of Cervical Radiation and Incidence of Carcinoma of the Pharynx, Larynx, and Thyroid. (Eng) Sakamoto, A. (Dept. Pathology, Cancer Inst., Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Sakamoto, G.; Sugano, H. *Cancer* 44(2): 718-723; 1979.

The possible radiosensitivities of the pharynx, larynx, and thyroid for the induction of carcinoma were compared by analyzing 2,030 malignancies of one of these structures seen between 1947 and 1976. Most malignancies in the pharynx and larynx were squamous cell carcinomas, while adenocarcinoma was overwhelmingly

represented in the thyroid. There were 15 carcinomas in 14 patients (4 men, 10 women) with possible radiation-induced malignancies. All 14 patients had received x-ray therapy (1,300-20,000 rads, mean 6,600 rads) for benign neck lesions. Six cases of possible radiation-induced carcinoma occurred among 202 hypopharyngeal malignancies, while only 2 were observed among 1,208 in the larynx; 6 of 238 thyroid malignancies could have been radiation-induced. The hypopharynx and larynx were equally irradiated, but the difference in the frequency of radiation-induced carcinomas between these structures was statistically significant. The av interval between initiation of irradiation and onset of cancer was 28 yr. Possible radiation-induced carcinomas in the hypopharynx, larynx, and thyroid usually developed earlier than comparable naturally occurring carcinomas. It is concluded that the hypopharynx should be included in the high-risk group of human structures for cancer occurrence after irradiation. (16 refs)

- 79-7141 Interaction of Factors Associated with Cancer of the Nasopharynx. (Eng) Lin, T. M. (Dept. Public Health, Natl. Taiwan Univ., Coll. Medicine, #1 Sec. 1, Jin-Ai Rd., Taipei, Taiwan); Yang, C. S.; Tu, S. M.; Chen, C. J.; Kuo, K. C.; Hirayama, T. *Cancer* 44(4): 1419-1423; 1979.

The interaction of factors that have been associated with nasopharyngeal carcinoma (NPC) was studied retrospectively in 351 NPC patients. These factors include smoking, working in poorly ventilated areas (WPV), use of nasal balms or oil for nasal and throat problems (NBO), use of herbal drugs (HD), and high anti-Epstein-Barr virus (EBV) antibody titers. In general, the risk of NPC increased with the level of exposure to each of these factors. There appeared to be a synergistic association between smoking and each of the other factors, especially HD or WPV. Other synergistic interactions were seen between WPV and all other factors, between HD and increased anti-EBV antibody titer, and between NBO and HB plus increased anti-EBV antibody titer. (17 refs)

- 79-7142 Lymphomas in Renal Transplant Recipients: A Search for Clustering. (Eng) Kinlen, L. J. (Environmental Epidemiology Branch, Natl. Cancer Inst., Bethesda, MD 20205); Hoover, R. N. *Br J Cancer* 40(5): 790-802; 1979.

The registry of the American College of Surgeons was examined for evidence of space and time clustering of lymphomas among renal transplant recipients. Of the 16,869 patients treated at 283 transplant centers, 54, from 39 centers, developed lymphoid tumors. The overall incidence of lymphomas was 1.3/1,000/yr. Centers at which one transplant patient developed lymphoma subsequently showed an even higher subsequent rate (1.89/1,000). Although these differences were statistically significant, they suggested the possible involvement of a transmissible agent in the etiology of lymphoma. However, there was no evidence of space-time clustering or of a higher incidence in transplant patients who could have had direct contact with lymphoma patients in the in-

duction period; this suggests that the above findings were not due to the effects of a transmissible agent. (3 refs)

- 79-7143 Histopathological Changes of the Nasal Mucosa in Active and Retired Nickel Workers. (Eng) Torjussen, W. (Central County Hosp., Kristiansand, Norway); Solberg, L. A.; Hogetveit, A. C. *Br J Cancer* 40(4): 568-580; 1979.

Nasal biopsy specimens from the middle turbinate in 318 active and 15 retired nickel workers and in 57 controls were examined histologically to study the prevalence of nasal carcinoma or possible precancerous mucosal changes in nickel-exposed individuals. The histopathological changes were evaluated according to a point-score scale, and the results were correlated with age, smoking habits, duration and type of nickel exposure, and nickel concentrations in nasal mucosa, plasma and urine. The explanatory values of these factors on the histopathology were estimated by stepwise multiple regression analysis. Two nickel workers from the roasting/smeltering department (0.6%), both employed 28 yr at the plant, had nasal carcinoma; and carcinoma in situ was found in one of these cases. Epithelial dysplasia was found in about 12% of active and 47% of retired nickel workers. One of the controls, a male carpenter, had dysplasia. These histopathological changes may be precancerous lesions, as they are almost exclusively found in active and retired nickel workers with enhanced risk of nasal carcinoma. Loss of respiratory epithelium and development of squamous epithelium were regarded as nonspecific histopathological changes. These changes were seen in all groups, although the incidence was significantly higher in the nickel-exposed groups. Duration of nickel exposure, type of nickel-refining work, and tobacco consumption were the independent variables that, taken together, had the highest explanatory values for the histopathological changes. (26 refs)

- 79-7144 Histopathologic Changes of Nasal Mucosa in Nickel Workers. A Pilot Study. (Eng) Torjussen, W. (Central County Hosp., 4601 Kristiansand S, Norway); Solberg, L. A.; Hogetveit, A. C. *Cancer* 44(3): 963-974; 1979.

Histologic examination of standard biopsy specimens from nasal mucosa were performed on 98 former and present employees at a nickel refinery and on 61 controls. Histologic characteristics of the epithelium were graded blindly according to a point score table. The histologic scores were compared to certain epidemiologic data, such as the degree and duration of nickel exposure, duration of industrial work without nickel exposure, age, and smoking habits. High histologic scores were correlated to high nickel exposure, to the duration of this exposure, to age, and to industrial work not involved with nickel. One person with nasal carcinoma was detected in the nickel-exposed group. During the investigation period, three additional nasal carcinomas in former nickel workers were discovered and later included in the study. Furthermore, 18 cases of epithelial dysplasia were found in the nickel-exposed group, whereas none were found among controls. The subjects with nasal carcinomas were or had been working with processes that gave an estimated high nickel dust exposure. All the individuals with epithelial dysplasia were nickel process workers. (32 refs)

Hosp., Kristiansand S, Norway). *Acta Otolaryngol (Stockh)* 88(3/4): 279-288; 1979.

Rhinoscopy and x-ray examination were performed on 318 nickel workers and 57 controls to study the usefulness of these methods in detecting cancerous and precancerous mucosal changes. The clinical and radiological findings were compared with histopathological data and mucosal nickel concentrations determined in nasal biopsy material from the middle turbinate, with duration of nickel exposure, and with tobacco smoking habits. The nickel-exposed subjects had a statistically significant increase in pathological changes over the controls (43% vs 26%, $0.01 < p < 0.02$), mainly due to differences in the frequency of hyperplastic rhinitis. Thirteen nickel workers (4%) had nasal polyps. Two of these cases, both employed at the nickel refinery for 28 yr, appeared to have nasal carcinoma revealed by histological examination. No distinct association was established between rhinoscopic findings and epithelial dysplasia found by histological examination. The explanatory values for the rhinoscopic findings of different factors, such as working category, age, duration of nickel exposure, grams tobacco smoked per week, and nickel content of nasal mucosa, were evaluated by applying a stepwise multiple regression analysis. Number of years from first employment at the nickel refinery and tobacco consumption were the only explanatory factors that showed a statistically significant correlation to the rhinoscopic findings. The radiological examination revealed few characteristic findings. Chemical analysis of cigarettes handrolled by nickel workers showed high nickel concentrations compared with uncontaminated cigarettes. (13 refs)

- 79-7146 Malignant Neoplasms in Saudi Arabia. (Eng) Stirling, G. (Pathology Dept., Coll. Medicine and Allied Sciences, P.O. Box 1540, Jeddah, Saudi Arabia); Khalil, A. M.; Nada, G. N.; Saad, A. A.; Raheem, M. A. *Cancer* 44(4): 1543-1548; 1979.

A series of 1,000 consecutive malignant neoplasms diagnosed over a 3-yr period in Saudis living in the Western Region of Saudi Arabia was analyzed. The most common malignancy was skin cancer (155 patients), with squamous cell carcinoma being most prevalent (73). This was followed by malignant lymphoma (128 patients), of which Hodgkin's disease was the most common (56) and showed a male predominance (1.9:1.0). The peak age for Hodgkin's disease was the second decade, compared with the third decade in Western countries. The proportions of the subtypes of Hodgkin's disease were also different from those encountered in many other countries, in that there was a greater proportion of the mixed cellularity type (60.7%) and a lower proportion (8.9%) of the nodular sclerosis type. Eighteen of the 39 patients with reticulum cell/poorly differentiated lymphomas presented with primary abdominal malignancies, and six of these patients were girls (7 mo-11 yr old). The mouth, including the tongue, was the most common site for gastrointestinal system cancer (81 patients), followed by the esophagus (59 patients). The colon and rectum accounted for 40 cancer cases. Only 40 cases of lung cancer were diagnosed during this period. Breast cancer (74 cases) was the most common malignant neoplasm among women. Cervical carcinoma was the most common female genital tract malignancy (42 patients), followed by cancer of the uterus (24 cases) and ovary (21 cases). There were 52 soft tissue sarcomas. No malignant neoplasms of the CNS were detected. (16 refs)

- 79-7147 Trophoblastic Tumors in Greenland. (Eng) Nielsen, N. H. (Dept. Pathology, Rigshospitalet, Copenhagen,

Denmark); Hansen, J. P. *J Cancer Res Clin Oncol* 95(2): 177-186; 1979.

The incidences of hydatidiform mole, invasive mole, and choriocarcinoma in female natives of Greenland during the period 1950-1974 were studied. During this period, 37 cases of hydatidiform mole not followed by malignancy and 11 cases of invasive, trophoblastic tumors (IGTT) occurred among the women studied. The overall incidence of benign mole was 1:850 births, only slightly higher than most incidences in low-risk areas like Western Europe, North America, Australia, and Israel. In contrast, the overall incidence of IGTT, 1:2,861 births, and the minimum incidence of histologically confirmed choriocarcinoma, 1:5,245 births, are among the highest population-based incidences on record. A marked increase in incidence of both hydatidiform mole and IGTT was found late in reproductive life. A recent high incidence of mole among teenagers increased the incidence with statistical significance during the last 10 yr of the study, whereas max incidence of IGTT was found between 1960 and 1964. A strong association existed between hydatidiform mole and IGTT. During the study period, Greenlandic women with hydatidiform moles had a 20% risk of developing IGTT, and 64% of IGTT cases were preceded by pregnancy during which a mole was found. Four cases of benign mole, but no case of IGTT, occurred among the small group of Danish women living in Greenland. The incidence, 1 mole/685 births, was higher than among the indigenous population, although the latter had a lower socioeconomic status. The reason for the high incidence of IGTT among indigenous Greenlanders remains unknown. The predominant HL-A 9 antigen could reflect genetic predisposition. (49 refs)

- 79-7148 Variation of Melanoma Incidence with Latitude in North America and Europe. (Eng) Crombie, I. K. (Dept. Social Medicine, Univ. Birmingham, Birmingham, England). *Br J Cancer* 40(5): 775-782; 1979.

The relationship between melanoma incidence and latitude was investigated among North American and European Caucasians. Data collected by 43 population-based cancer registries was used. In North America, melanoma incidence increased with decreasing latitude, supporting the role of UV light in the induction of melanoma. Within England, data from the National Cancer Registration scheme also showed the trend of increased frequency of melanoma with decreasing latitude. In contrast, the trend across Europe was in the opposite direction, of increasing melanoma incidence with increasing latitude. It is suggested that across Europe, there is a range of skin color from dark in the south to light in the north, which gives rise to a range of susceptibility to the induction of melanoma by UV. The effect of this susceptibility must be large enough to overwhelm the opposing effect of decreased UV intensity at higher latitudes, and this emphasizes the dangers of excessive solar exposure to fair-skinned individuals. The population of England may be a sufficiently random mix of skin color, owing to repeated invasions, for the effect of UV intensity to be observed. (15 refs)

- 79-7149 Plasma IgA, IgG and IgM and Their Relationship to Breast Cancer in British, Japanese and Hawaiian-Japanese Women. (Eng) Wang, D. Y. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Goodwin, P. R.; Bulbrook, R. D.; Hayward, J. L.; Abe, O.; Utsumiya, J.; Kumaoka, S.; Greenwood, F. C.; Glober, G.; Stemmerman, G. *Cancer* 44(2): 492-494; 1979.

IgA, IgG, and IgM levels were measured in 44 normal Hawaiian-Japanese women, 35 British women, and 37 Japanese women living in Tokyo, none of whom had been taking steroidal contraceptives for ≥ 1 yr. The Hawaiian Japanese women had the same levels of IgA as Japanese women, the same levels of IgM as British women, and were intermediate for IgG levels. The mean level of IgM in 28 Japanese patients with breast cancer was similar to that in normal British or Hawaiian-Japanese women and significantly lower than that in normal Japanese women ($p < 0.01$). The finding that Hawaiian-Japanese women with an increased risk of breast cancer, compared with indigenous Japanese, have an IgM level similar to British women and Japanese patients with breast cancer supports the hypothesis that differences in IgM levels reflect alterations in humoral immunity and that these differences are associated with racial differences in breast cancer incidence. (10 refs)

- 79-7150 Plasma and Urinary Androgens in Women with Varying Degrees of Risk of Breast Cancer. (Eng) Wang, D. Y. (Imperial Cancer Res. Fund, Lincoln's Inn Fields, London WC2A 3PX, England); Moore, J. W.; Thomas, B. S.; Bulbrook, R. D.; Hoare, S. A.; Tong, D.; Hayward, J. L. *Eur J Cancer* 15(10): 1269-1274; 1979.

Plasma levels of dehydroepiandrosterone (DHE), DHE sulfate Δ^4 -androstenedione, and Δ^5 -androstenediol were determined in 386 healthy women (30-69 yr of age) assigned to four groups with mean calculated risk of breast cancer (estimated from the age of menarche, age at first child, family history, and amount of etiocholanone in the urine) of 0.016, 0.023, 0.051, or 0.111, respectively. Plasma DHE sulfate and Δ^5 -androstenediol levels in the group with highest estimated risk were significantly lower than in the other three groups; however, there were no significant differences among postmenopausal women. No correlation between estimated cancer risk and levels of DHE Δ^4 -androstenedione was observed. (13 refs)

- 79-7151 Cancer Register in Greenland. (Dan) Boggild, J. (Landslaegeembedet, Copenhagen, Denmark); Clemmesen, J.; Hart Hansen, J. P.; Nielsen, N. H. *Ugeskr Laeger* 141(28): 1946-1947; 1979.

Epidemiological data on cancer in Greenland are presented. Very high incidences of cancer of the uterine cervix, rhinopharynx, salivary glands, and esophagus have been reported. Between 1970 and 1974, the age-adjusted incidence of cancer of the uterine cervix was 84.8/100,000, which is more than 2.5 times higher than the incidence in Denmark during the same period. The incidence has risen considerably compared with that during the preceding 15 yr. The age-adjusted incidence of rhinopharyngeal cancer between 1965 and 1976 was 12.3 in men and 8.5 in women, which is slightly lower than the highest incidence rates in China. Most salivary gland tumors found in Greenland are anaplastic carcinomas with lymphocyte infiltration. As the salivary gland tumor tissue is histologically identical with the rhinopharyngeal cancer, many may be metastases. Statistically significant cumulation of esophageal cancer was found in the three southernmost districts of Greenland. Between 1965 and 1974, the incidence in both men and women was five times higher than in the rest of Greenland. The ecological conditions in southern Greenland may play a role in this high incidence of esophageal cancer. (4 refs)

- 79-7152 Incidence of Myeloid Leukaemia in Lancashire. (Eng) Geary, C. G. (Dept. Clinical Hematology, Univ. Man-

chester, Manchester, England); Benn, R. T.; Leck, I. *Lancet* 2(8142): 549-551; 1979.

The identification of a cluster of cases of acute and chronic myeloid leukemia in a single general practice in Lancashire prompted a formal analysis of the incidence of these diseases in most of Lancashire, based on data collected by the Regional Cancer Registry in Manchester during a 12-yr period. The number of registered cases of myeloid leukemia was determined and converted to a standardized registration ratio. The analysis revealed a doubling in the standardized registration ratio for myeloid leukemia in Lancashire as a whole between 1965-1970 and 1971-1976. The localities into which Lancashire was divided for this analysis did not differ significantly from one another in the increases observed. The increased incidence of leukemia in this area represents a substantially larger increase than that which has occurred nationally in the same period and is unlikely to be due solely to more accurate diagnosis or reporting. Although no chemical leukemogen was identified, it is possible that a proportion of the cases are due to extrinsic or intrinsic leukemogens, acting in susceptible individuals. (13 refs)

- 79-7153 Axillary Forms of Hodgkin's Disease. Considerations on Etiology and Clinical Characteristics. (Ger) Weh, H. J. (Institut de Recherches sur les Leucémies et les Maladies du Sang, U.E.R. d'Hématologie, Hôpital Saint-Louis, 2, place du Docteur Fournier, F-75475 Paris Cedex 10, France); Andrieu, J. M. *Med Welt* 30(40): 1460-1462; 1979.

A possible correlation between the rare axillary localization of Hodgkin's disease (HD) with injury and infection of the hands or arms was studied in 16 HD patients. The patients had Stage I HD localized to one axillary region only (LAR). The av age at diagnosis was 40.9 yr, compared with an av of 28.9 yr among 447 HD patients with usual localizations. The group with LAR-HD contained only 3 women; this sex distribution is different ($p < 0.001$) from the men:women ratio of 1.3 in the usual HD group. Only 4/16 LAR patients reported no manual labor in their work history, and 3 of these reported frequent injury or irritation of the arms or axilla (eg, shaving injury). The remaining 12 patients reported at least 10 yr of manual labor that resulted in frequent hand and arm injuries. Manual labor is the main occupation of 35% of the French population, from which the LAR group was drawn. Two of the LAR group had lymphocyte-rich HD, 9 had nodular sclerosing HD, 4 had mixed-cellular HD, and 1 had lymphocyte-poor HD. Fourteen of these patients are in full remission, with an av survival time of 41 mo, and two died at 69 and 75 mo. Isolated localization of HD to the axilla has been found in 2.5%-5.7% of HD cases in different series. The LAR group described differs from the usual HD group in the higher age of diagnosis and the preponderance of men and manual laborers. Frequent injury of the hands or arms may provide an entrance for an agent causing HD in susceptible individuals. (25 refs)

- 79-7154 Occupational Handling of Chemicals Preceding Hodgkin's Disease in Men. (Eng) Olsson, H. (Dept. Oncology, Univ. Hosp., S-221 85 Lund, Sweden); Brandt, L. *Br Med J* 2(6190): 580-581; 1979.

The case records of 88 men treated for Hodgkin's disease at a Swedish hospital during 1973-1978 were examined for a possible relationship between Hodgkin's disease and occupations involving the handling of chemicals. Seventeen men had occupations in-

dicating that they handled chemicals (chemists, 2; painters and sprayers, 5; glass and pottery workers, 5; rubber product workers, 2; and 1 each chemical processing, plastics, and photographic laboratory workers). In three control groups (two consisting of persons without cancer and one of 32 men with chronic leukemias), 2/100, 3/100, and 1/32 individuals, respectively, had occupations involving chemical handling. The differences between the group with Hodgkin's disease and each of the control groups were significant. Only 2/35 patients with Hodgkin's disease aged 20-30 yr were occupationally exposed to chemicals compared with 8/31 of those aged 31-50 yr and 7/22 of those over 50-65 yr old. This may indicate that occupational exposure to chemical oncogenic agents may be important in Hodgkin's disease in men over 30 yr old while other etiological factors may be more important in the younger age groups. The results also suggest that an effort should be made to define environmental hazards that may be important in the development of Hodgkin's disease. (3 refs)

- 79-7155 The Chemotherapy of Plasma-Cell Myeloma and the Incidence of Acute Leukemia. (Eng) Bergsagel, D. E. (NCIC Epidemiology Unit, Faculty Medicine, Univ. Toronto Hosp., McMurrich Building, Toronto, Ontario M5S 1A8, Canada); Bailey, A. J.; Langley, G. R.; MacDonald, R. N.; White, D. F.; Miller, A. B. *N Engl J Med* 301(14): 743-748; 1979.

Previously untreated myeloma patients (196 men, 168 women) were randomly assigned to one of three treatment groups: Group A, melphalan and prednisone followed by either cyclophosphamide or carmustine if relapse or progression occurred (125 patients); Group B, melphalan, cyclophosphamide, carmustine, and prednisone on an alternating schedule (123 patients); and Group C, the same four drugs on a concurrent schedule (116 patients). The composition of the three groups was similar with respect to age, sex and M-protein types, and various prognostic factors (performance status, clinical stage, and the initial blood urea nitrogen). There were no significant differences in response rate or survival among the three groups. It was not possible to identify a subgroup that responded better to the combination of alkylating agents than to melphalan and prednisone alone. The survival of patients producing only λ chains was shorter than expected. Acute leukemia developed in 14 patients, and ring sideroblasts, a presumed preleukemic change, were reported in an additional 18 patients. There was no significant difference in the incidence of leukemia among the three groups. The observed incidence of acute leukemia was much greater than expected for all the groups. It is concluded that the combination of the four drugs is no better than melphalan and prednisone for inducing responses or prolonging the survival of myeloma patients. (25 refs)

- 79-7156 Case-Control Study of Hair Dye Use by Patients with Breast Cancer and Endometrial Cancer. (Eng) Stavray, K. M. (Ontario Cancer Treatment Res. Foundation, Dept. Epidemiology, Univ. Western Ontario, London, Ontario N6A 5B7, Canada); Clarke, E. A.; Donner, A. *J Natl Cancer Inst* 63(4): 941-945; 1979.

A case-control study of permanent and semipermanent hair dye use by women with breast or endometrial cancer was carried out. The patients included 50 breast cancer patients in London, Ontario, 35 breast cancer patients in Toronto, and 36 patients with endometrial cancer in Toronto. In London, controls consisted of hospitalized women with diseases other than cancer; in Toronto, controls were selected from women living in the same

neighborhood as the cancer patients. The results did not suggest an increased risk of either breast or endometrial cancer in users of permanent or permanent and semipermanent dyes combined. Although the numbers of cases and controls were small, the consistency of the results for both sites, in both study centers, and the absence of any clear positive relationship between various measures of intensity of use and cancer risk provided evidence that a large increase in risk was not missed. (21 refs)

- 79-7157 Breast Cancer in Black American Women. (Eng) Austin, H. (Dept. Epidemiology, Harvard Sch. Public Health, 677 Huntington Avenue, Boston, MA 02115); Cole, P.; Wynder, E. *Int J Cancer* 24(5): 541-544; 1979.

Results of a case-control study of breast cancer among Black American women conducted in seven hospitals in New York city from 1969 to 1975 are reported for 127 cases and 317 controls. Compared to women with a first birth before age 19 yr, those with a first birth after 25 yr of age had a relative incidence rate for breast cancer of 3.8 and 2.2 for the pre- and postmenopausal age-groups, respectively. Compared to nulliparous women, parous women had a relative incidence rate of 0.6 and 0.7 for pre- and postmenopausal women, respectively. The incidence rate for women reaching menopause after age 49 yr was estimated to be 3.1 times that of women with a menopause before 45 yr of age. Thus, the known risk factors for breast cancer among Whites also appear to apply to Blacks. The incidence rate of breast cancer has increased among younger Blacks since 1947 and is now similar to that of younger Whites, while among older women the incidence rate is still appreciably higher for Whites. This pattern could be explained by common exposures to etiological agents (eg, dietary or environmental factors) among women of both races born since about 1925. (14 refs)

- 79-7158 Cancer and Scleroderma. (Eng) Duncan, S. C. (Dept. Dermatology, Mayo Clinic, Mayo Foundation, Rochester, MN); Winkelmann, R. K. *Arch Dermatol* 115(8): 950-955; 1979.

Experience with patients who had both scleroderma and an internal malignancy is presented. Of 2,141 scleroderma patients seen at the Mayo Clinic between 1959 and 1975, 78 had 87 internal malignancies. The relative frequency of the types of cancers was similar to that for the general population. The increased numbers of patients with breast and uterine carcinomas were consistent with the female preponderance in scleroderma. Contrary to previous reports, lung carcinoma was not the most frequent malignancy associated with scleroderma. Breast carcinoma was the most frequent malignancy (18 cases), followed by lymphoma-leukemia malignancies (11 cases). Both conditions developed within a 3-yr period in 45/66 patients with systemic scleroderma, and this subgroup comprised a high mortality group. (44 refs)

- 79-7159 Mathematical Models and the Statistical Analyses of Cell Transformation Experiments. (Eng) Gart, J. J. (Biometry Branch, Div. Cancer Cause and Prevention, NCI, Bethesda, MD 20205); DiPaolo, J. A.; Donovan, P. J. *Cancer Res* 39(12): 5069-5075; 1979.

Statistical methods are developed and applied to the fitting of the one-hit curves to chemically induced transformations in Syrian

hamster colonies. Data from several experiments in two laboratories are shown to fit the model well for benzo(a)pyrene at all but the highest doses. The ratio of the estimated parameters of the one-hit curves ("transformicities") is proposed as a measure of the enhancement by x-irradiation. Statistical tests for possible nonrandom variation among dishes are developed for use when a sample of dishes is used to estimate the total number of surviving cells. The methods of fitting and estimation are also extended to this case. Further analyses exclude selection as an explanation for the observed increase in transformation frequency with increased carcinogen concentration. The reproducibility of the fit of the one-hit model and the radiation enhancement measures is attributed to the uniqueness of this in vitro system in which the direct target cell-insult interaction is not modulated by host intervention. (16 refs)

- 79-7160 Risk Factors for Nodular Sclerosis and Other Types of Hodgkin's Disease. (Eng) Henderson, B. E. (Dept. Community and Family Medicine, Univ. Southern California Sch. Medicine, 2025 Zonal Avenue, Los Angeles, CA 90033); Dworsky, R.; Pike, M. C.; Baptista, J.; Menck, H.; Preston-Martin, S.; Mack, T. *Cancer Res* 39(11): 4507-4511; 1979.

The age-adjusted incidence rates of nodular sclerosis in Los Angeles County from 1972-1975 were 58% lower in Mexican-Americans and 42% lower in blacks than in non-Mexican whites. In the latter group, rates were the same for each sex, with the curve of age-specific incidence peaking in young adulthood. The incidence of nodular sclerosis was directly associated with social class. In contrast, the rates for other histological varieties of Hodgkin's disease (lymphocyte predominance, mixed cellularity, lymphocyte depletion) were 12% lower in Mexican-Americans and 34% lower in blacks. In non-Mexican whites, the rates were 92% higher in men and increased gradually with age; there were no clear trends with social class. These characteristics support the hypothesis that, at least for purposes of etiology, the nodular sclerosis form of this disease should be considered a distinct entity. Self-administered questionnaires were completed by 218 of the 1972-1973 Hodgkin's disease patients and 218 individually matched neighborhood controls. Significantly high risk ratios for Hodgkin's disease were found for prior appendectomy (risk ratios = 1.9, $p = 0.01$) and for past amphetamine use (risk ratios = 3.0, $p = 0.01$). The elevated risk associated with amphetamine use had been found in a previous study. (22 refs)

- 79-7161 Hodgkin's Disease in Childhood. (Eng) Alsabti, E. A. (7511 Teall Run, Houston, TX 77071). *J Cancer Res Clin Oncol* 95(1): 75-81; 1979.

The relationship of histologic type to age, sex, and survival was studied among 103 children with Hodgkin's disease (HD) in Iraq. The children ranged in age from 1.5-16 yr, and the male:female ratio was 3.1:1. Subtype distribution did not vary significantly with sex. Of the 103 cases, 16 showed lymphocytic predominance (LP), 13 showed lymphocytic depletion (LD), 13 were classified as nodular sclerosis (NS), and 62 showed mixed cellularity (MC). Mediastinal masses were observed in 7/13 NS cases; the predominant location in other subtypes was the cervical lesion. Metastasis was found in four patients with the MC subtype and one with LP. Lymph node biopsies of three patients, all of whom were from rural areas, showed granulomatous inflammation in association with HD; two of these patients had a family history of tuberculosis. Survival during the first year after diagnosis was significantly higher among NS patients (96%) than among MC pa-

tients (72%) ($P < 0.005$). None of the patients with LD subtype survived beyond the first year. The 3-yr survival rates were similar among patients with NS and LP subtypes. (34 refs)

79-7162 Acquaintance Networks Among Leukemia and Lymphoma Patients. (Eng) Greenwald, P. (Div. Epidemiology, New York State Dept. Health, Tower Bldg., Empire State Plaza, Albany, NY 12237); Rose, J. S.; Daitch, P. B. *Am J Epidemiol* 110(2): 162-177; 1979.

A quantitative epidemiologic method that utilizes detailed social interaction data was developed to determine if acquaintanceship patterns among leukemia and lymphoma patients differ from those among healthy people. A case-control study of clustering through acquaintanceship among 20 lymphoma and 17 leukemia patients was conducted for the years 1967 through 1972 in Orleans County, New York. Data on acquaintanceship linkage were gathered from the source cases and controls, and from their acquaintances yielding a data base of 13,409 unique individuals linked by acquaintances. Three different analyses were carried out: a statistical analysis of linkage via intermediaries of case pairs in comparison with control pairs; a computer simulation of disease transmission from selected source cases to selected targets and controls based on the acquaintance data; and a secondary attack rate type analysis. The first two types of analysis yielded statistically significant case-control differences at the .05 level. The third method also yielded a positive result but was not subject to quantitative hypothesis testing. These epidemiologic methods for disease with long induction periods merit further study. (33 refs)

79-7163 Comparison of Virus-positive and Virus-negative Cases of Feline Leukemia and Lymphoma. (Eng) Francis, D. P. (Dept. Microbiology, Harvard Univ. Sch. Public Health, Boston, MA 02115); Cotter, S. M.; Hardy, W. D.; Essex, M. *Cancer Res* 39(10): 3866-3870; 1979.

The clinicopathological and epidemiological aspects of 184 cases of feline leukemia and lymphoma diagnosed in Boston between 1972 and 1976 were investigated. Fifty-eight percent of cases were lymphoma, and 42% were leukemia. Sixty-seven percent of the cats had positive fluorescent antibody tests for circulating feline leukemia virus. The rest (33%) were virus-negative. The virus-positive and virus-negative cases were remarkably similar, except for their age at diagnosis. Virus-negative cats tended to be older (mean age at diagnosis, 4.9 yr) compared with virus-positive cats (3.5 yr). Among the 22 cats in which leukemia or lymphoma was diagnosed after the age of 8 yr, 15 were virus-negative. The minimum mean induction period (time from first positive virus test to diagnosis of cancer) for 19 cats that were virus-positive and healthy at their first test was 16.7 mo (range, 2-41 mo). (30 refs)

79-7164 Idiopathic Refractory Sideroblastic Anemia: Incidence and Risk Factors for Leukemic Transformation. (Eng) Cheng, D. S. (Dept. Internal Medicine, Univ. Utah Coll. Medicine, Salt Lake City, UT 84132); Kushner, J. P.; Wintrobe, M. M. *Cancer* 44(2): 724-731; 1979.

The clinical course of 29 patients (19 men, 10 women; aged 19-88 yr) with idiopathic refractory sideroblastic anemia (IRSA) is reported. Four patients died with acute leukemia an av of 6.8 yr after the onset of the anemia. A literature review revealed that

31/297 patients with IRSA developed acute leukemia. Of the 31 cases, 9 were reported in detail; the characteristics of these 9 patients and the 4 reported in this study with IRSA terminating in acute leukemia were compared with those of the 25 patients in the present series who did not develop leukemia. The risk factors for leukemic transformation include a more severe anemia at presentation, a lower reticulocyte count, an increased transfusion requirement, and thrombocytopenia. There was a male preponderance of 10:3 in the leukemic group, compared with the overall male:female ratio of 2:1 in patients with IRSA. A low leukocyte alkaline phosphatase (LAP) score also appeared to be associated with leukemic transformation. (57 refs)

79-7165 Cancer in a Community Subject to Air Pollution by Solvent Vapors. (Eng) Capurro, P. U. (P.O. Box 218, Elkton, MD 21921). *Clin Toxicol* 14(3): 285-294; 1979.

A population of 117 people exposed for >5 yr to solvent vapors from a chemical plant were followed for 6 yr, October 1968 through September 1974. Solvent vapors detected in the study were: methyl ethyl ketone, methyl isobutyl ketone, acetone, methanol, isopropyl alcohol, butanol, amyl alcohol, isoamyl alcohol, benzene, toluene, xylene, phenol, nitrophenol, nitrochlorobenzene, chlorobenzene, ethyl acetate, ethyl ether, furan, tetrahydrofuran, methylchloride, methylene chloride, chloroform, carbon tetrachloride, trichloroethylene, tichloroethane, acrylonitrile, and formaldehyde. During this period there were 14 deaths, 7 due to malignancy, compared to an expected 6 deaths, one of which would be from cancer. Lymphomas were definitely increased (4 in 6 yr); these 4 people also worked at one time in a paper mill which preceded the chemical plant in the same location. The ratio of observed to expected lymphoma deaths was 3/9.0187 or 160-fold. All of the people who developed lymphomas were diagnosed ≥ 4 yr after the initial exposure to solvents. Other cancers diagnosed in this group of 23 cases include cancer of the pancreas and larynx, Hodgkin's disease, leukemia, and reticulum cell sarcoma. (11 refs)

79-7166 Anaplastic Carcinoma of the Thyroid in a Population Irradiated for Hodgkin's Disease, 1910-1960. (Eng) Getaz, E. P. (322 E. Center St., West Bridgewater, MA 02379); Shimaoka, K. *J Surg Oncol* 12(2): 181-189; 1979.

The incidence of anaplastic carcinoma of the thyroid (ACT) was studied in 520 patients treated for Hodgkin's disease during the period 1910-1960. Of the 520 patients, 328 were male, 192 were female; 505 were white, and 15 were black. The mean age was 38.6 yr (range, 1.75-80 yr). Of the 494 patients who had been irradiated, 439 had been irradiated in the cervical and/or mediastinal areas. The mean survival time was 4.21 yr and was 6 mo longer for female patients than for male patients. The mean survival of the irradiated group was 4.95 yr. Of the 141 patients who survived ≥ 5 yr, 2 developed anaplastic carcinoma (1.42%). These two patients were among only six who survived >30 yr (33.3%). The incidence of ACT in Hodgkin's disease is far higher than would be expected in the population at large (0.8/100,000). It is possible that patients receiving a high dose of radiation to the cervical region, particularly when bipedal lymphangiography has been carried out, should remain on long-term thyroid suppressive therapy. (55 refs)

79-7167 Anatomic Distribution of Malignant Melanoma of the Skin Among Non-Caucasians in Hawaii. (Eng) Hinds,

M. W. (Epidemiology Program, Cancer Center Hawaii, Univ. Hawaii, Honolulu, HI). *Br J Cancer* 40(3): 497-499; 1979.

The anatomical distribution of malignant melanoma among 64 non-Caucasian patients (Japanese, Hawaiian/part-Hawaiian, Filipino, and Chinese) in Hawaii during 1960-1977 is reported. Among men, the most common site was the feet (17/41), followed by the trunk (8), upper extremities (8), and head and neck (7). Among women, the head and neck was the most common site (6/23), followed by the lower extremities (5) and the feet (5). Thus, malignant melanoma is common on the feet of Hawaiian non-Caucasians, a pattern similar to that seen in blacks. The use of open-toed shoes and sandals is very common in Hawaii, lending support to the theory that trauma to the skin of the feet may be a predisposing factor in malignant melanoma of the feet. (9 refs)

79-7168 Skin Cancer Epidemiology: Research Needs. (Eng) Scotto, J. (Demography Section, Biometry Branch, NCI, NIH, Public Health Service Dept. Health, Education, Welfare, Bethesda, MD 20014); Fears, T. R. *Natl Cancer Inst Monogr* (50): 169-177; 1978.

An epidemiological study of skin cancer by the Environmental Protection Agency and the NCI now in progress is reviewed, and a detailed protocol of the study is provided. Past epidemiological data concerning carcinogenic UV rays (UV-B) and nonmelanoma skin cancer are too sparse and lack certain details such as exposure patterns and skin types, and the geographical area has been too narrow to allow for more precise measurement of the effects of stratospheric ozone depletion. The present relationships could change drastically with the addition of a few more points (geographical locations) and location-specific and demographic factors need to be evaluated. A special skin cancer study from June 1, 1977 to May 31, 1978 being conducted by NCI and the Environmental Protection Agency is aimed at determining the incidence of nonmelanoma skin cancer (basal and squamous cell carcinomas) in various population groups within the United States, and ascertaining and measuring the epidemiological factors that may contribute toward excess risk of nonmelanoma skin cancer in specific population groups. This study involves nine active areas within the contiguous United States, including a population of >20 million. The incidence and the interview compose this study: the basic incidence or morbidity survey is modeled after the earlier Third National Cancer Survey; the interview involves abstracts from medical records and a telephone interview questionnaire. The interview phase will provide the epidemiological data necessary to evaluate the degree of morbidity that may be related to high-risk factors. Samples of the physician's skin cancer record, the skin cancer abstract record, and the telephone questionnaire are provided. (13 refs)

79-7169 Reduced Prevalence of the Lucke Renal Adenocarcinoma in Populations of *Rana pipiens* in Minnesota. (Eng) McKinnell, R. G. (Dept. Genetics and Cell Biology, Univ. Minnesota, St. Paul, MN 55108); Gorham, E.; Martin, F. B.; Schaad, J. W. *J Natl Cancer Inst* 63(3): 821-824; 1979.

Northern leopard frogs (*Rana pipiens*) afflicted with the Lucke renal adenocarcinoma virtually disappeared from Minnesota in the autumn of 1977. Frogs from four sites in Minnesota counties with a previously high prevalence of Lucke renal tumor were studied. In the past decade, incidence averaged 4.2% in 29 collections (total, 1,870 frogs). No tumors were detected in 685 frogs autopsied in the

autumn of 1977 using the same method as in previous studies. Frog collections, each comprised of 20 or more animals, were compared for the presence or absence of tumor-bearing frogs. Significantly fewer collections contained tumor-bearing frogs in the autumn of 1977 than did previous collections. The decrease in tumor incidence may be due to the recent decline in the frog population in Minnesota; the spread of Lucke herpesvirus, the etiologic agent responsible for the tumor, is probably density-dependent. (20 refs)

79-7170 Gastric Remnant Carcinoma. (Eng) Klarfeld, J. (Dept. Medicine, Univ. Hosp. Cleveland-Case Western Reserve Univ., Cleveland, OH 44106); Resnick, G. *Cancer* 44(3): 1129-1133; 1979.

At the New York Hospital-Cornell Medical Center, 7 of 100 gastric carcinoma cases were identified as gastric remnant carcinoma and were analyzed and compared with prior reports in the literature. Gastric remnant carcinoma is noted in greatest incidence beginning approx 15 yr after surgery for benign gastric disease. The average age at time of diagnosis was 73 yr, with an average interval of 21.6 yr between surgery and tumor diagnosis. Only one of the seven patients was female. Although the etiology of this cancer is unknown, the high incidence of bile reflux and concomitant existence of histologic change may account for a premalignant environment in which the stomach assumes some absorptive function. Such new activity may result in the influx of potentially carcinogenic compounds and subsequent tumor development. Early diagnosis of remnant carcinoma following gastric surgery is important to improved prognosis, and endoscopic follow-up is recommended for all such patients beginning 10-15 yr postoperatively. (27 refs)

79-7171 Changing Trends and Prognostic Features in Endometrial Cancer Associated with Exogenous Estrogen Therapy. (Eng) Robboy, S. J. (Dept. Pathology, Massachusetts General Hosp., Boston, MA 02114); Bradley, R. *Obstet Gynecol* 54(3): 269-277; 1979.

Trends in the microscopic patterns of endometrial carcinoma were studied, and the biologic characteristics of cases associated with estrogen use were compared with those not associated with estrogen use. After each case was reviewed independently and in a random order by at least two pathologists, a diagnosis of cancer was agreed on in 274 patients who had been treated by five gynecologists at the Massachusetts General Hospital between 1940 and 1971. Six microscopic patterns were identified (adenocarcinoma, adenoacanthoma, atypical adenoacanthoma, adenosquamous carcinoma, clear-cell adenocarcinoma, and undifferentiated carcinoma). The frequency of each pattern relative to the other five changed only slightly during the 30-yr interval. The tumors that developed in estrogen users were more highly differentiated than those that developed in nonusers ($p < 0.005$) and were found at an earlier average age ($p < 0.02$). That the adenoacanthoma was associated with estrogen use more frequently (51%) than any other tumor type ($p < 0.02$) may reflect, in part, a similar and lower mean age of estrogen users (56 yr) and patients with adenoacanthoma (55 yr) compared with that of nonusers with the other forms of tumors (60-67 yr). Although the overall 5- and 10-yr survival rates of the estrogen users were higher than those of the nonusers, the differences between the two groups disappeared when the grade of the neoplasm was considered. (38 refs)

- 79-7172 Cancer in Persons with Inherited Blood Coagulation Disorders. (Eng) Forman, W. B. (Hematology/Oncology Section, Cleveland Veterans Admin. Hosp., 10701 East Blvd., Cleveland, OH 44106). *Cancer* 44(3): 1059-1061; 1979.

A mail survey of physicians who care for individuals with a bleeding diathesis was evaluated to assess the influence of an inherited blood coagulation disorder in the development of cancer in such individuals. In an estimated population of 10,500, 61 subjects with both disorders were identified. An apparent increase in cancer incidence in the genitourinary and musculoskeletal systems was noted. However, in the largest group (hemophiliacs), the primary cancer site was similar to that seen in an age- and sex-matched population. There did not appear to be a change in the onset of metastatic disease in individuals suffering from blood coagulation disorders, as compared to other cancer patients. (8 refs)

- 79-7173 Reduced Incidence of Endometrial Cancer Among Postmenopausal Women Treated with Progestogens. (Eng) Gambrell, R. D. (Dept. Endocrinology, Medical Coll. Georgia, Augusta, GA 30912); Massey, F. M.; Castaneda, T. A.; Ugenas, A. J.; Ricci, C. A. *J Am Geriatr Soc* 27(9): 389-394; 1979.

A prospective study begun in 1976 to determine the incidence of endometrial cancer in postmenopausal women was undertaken to investigate the possibility of an increased risk of this disease in women receiving estrogen therapy. A retrospective study for the year 1975 was added. During 8,170 patient-years in the 3-yr 1975-1977 period, 14 endometrial malignancies were diagnosed, yielding an annual incidence of 1.7/1,000 women. During the 3,792 patient-years of observation of estrogen-progestogen users, the incidence of endometrial cancer was 0.5/1,000. The incidence of this carcinoma among estrogen users (8 cases during 2,088 patient-years) was 3.8/1,000. The difference between these two groups was statistically significant ($p < 0.01$). One adenocarcinoma was detected in a patient who had used estrogen vaginal cream for 7 mo (incidence of 1.7/1,000 during 573 patient-years of observation). In the untreated women, during 1,515 patient-years, there were 3 endometrial cancers, for an incidence of 2.0/1,000. There was no significant difference between the untreated group and the estrogen users, and only a trend ($p < 0.21$) between the estrogen-progestogen users and the untreated women. Synthetic progestogens were used to treat 199 women with endometrial hyperplasia (a precancerous lesion) for 3-6 mo. The hyperplastic endometrium reverted to normal endometrium in 96.5%. The data indicate that progestogens afford some protection against the slightly increased risk of endometrial cancer from estrogen therapy. (16 refs)

- 79-7174 Prenatal Diethylstilbestrol Exposure and Human Genital Tract Abnormalities. (Eng) Herbst, A. L. (Dept. Obstetrics and Gynecology, Univ. Chicago Medical Sch., Chicago, IL 60612); Scully, R. E.; Robboy, S. J. *Natl Cancer Inst Monogr* (51): 25-35; 1979.

By October 1975, 284 cases of clear cell carcinoma of the genital tract had been classified as vaginal (169) or cervical (115). A striking rise in the incidence of this disease began in the late 1960's and continued into the 1970's. Among 222 completely investigated cases, diethylstilbestrol (DES), dienestrol, and hexestrol had been administered to about two-thirds of the patients' mothers during pregnancy. The prescribed doses ranged from 1.5-150 mg/day.

The total amount ingested during pregnancy varied from 135 mg to 18,200 mg. In all documented cases, therapy began prior to the 18th wk of pregnancy. Ninety percent of the patients were 14 yr of age or older at the time of diagnosis. The youngest was 7 yr of age and the oldest was 28 yr of age; the median age was 18-19 yr. Most of the vaginal carcinomas were located in the upper, anterior wall. The cervical tumors primarily involved the portio. Over 93% of patients with asymptomatic tumors were rendered disease-free after surgery or radiation therapy. In exposed patients without cancer, genital tract abnormalities included vaginal adenosis, most frequently of the upper anterior or posterior walls; cervical eversion or ectropion; and transverse cervical and vaginal ridges. The prevalence of adenosis was highest in daughters exposed prior to the 8th wk of pregnancy; no cases were detected among those exposed after the 18th wk in one epidemiological study. Evidence suggests a disturbance in müllerian duct development as the cause of these changes. Whether DES is only a teratogen or also a carcinogen is unknown. No increased incidence of cancer has been documented in exposed males. (32 refs)

- 79-7175 Diet and Urinary Steroids in Black and White North American Men and Black South African Men. (Eng) Hill, P. (American Health Foundation, Naylor Dana Inst. Disease Prevention, Dana Road, Valhalla, NY 10595); Wynder, E. L.; Garbaczewski, L.; Garnes, H.; Walker, A. R. *Cancer Res* 39(12): 5101-5105; 1979.

Urinary steroid hormone content was determined in 40- to 55-yr-old Black and White North American men and rural Black South African men and in Black South African men over 60 yr of age. Some of the men were maintained on their customary diets while other Americans and Africans were transferred to a vegetarian or Western diet, respectively. When eating their customary diet, Black South African men had lower levels of urinary estrogens and androgens than did Black and White North American men. The total androgen and estrogen content decreased significantly in Black North American men on the vegetarian diet and increased in Black South African men fed a Western diet. Urinary excretion of estrogens was higher in older than in younger rural Black South African men. Data indicated that a vegetarian diet modified androgen and estrogen metabolism in North American men and that a Western diet was associated with higher levels of urinary steroid hormones in young Black South African men. Diet-related changes in steroid metabolism in rural Black South African men were age dependent. Further clarification is needed of the relationship of the increased urinary excretion of steroid hormones in Black South African men, a low-risk group fed a Western diet, and the decreased excretion in Black and White North American men, high-risk groups fed a vegetarian diet, to the development of prostatic cancer. (61 refs)

- 79-7176 Cancer Mortality Among Printing Plant Workers. (Eng) Greene, M. H. (Environmental Epidemiology Branch, NCI, Landow 3C-07, Bethesda, MD 20205); Hoover, R. N.; Eck, R. L.; Fraumeni, J. F. *Environ Res* 20(1): 66-73; 1979.

A proportionate cancer mortality study was conducted among employees of the U.S. Government Printing Office. Although the study was limited by small numbers (a total of 347 cancer deaths, among males only), there was a significantly higher proportion of deaths from multiple myeloma, leukemia, Hodgkin's disease, and colon cancer. The excess deaths from myeloma were confined to white workers in the composing room, where exposure to lead is

the major occupational hazard, while deaths from leukemia occurred primarily in bindery workers who may have had exposure to benzene. Despite methodologic limitations, these findings are consistent with other epidemiologic and experimental studies suggesting that printers are at higher risk for certain cancers. (32 refs)

- 79-7177 Smoking and Coffee Consumption in Three Groups: Cancer Deaths, Cardiovascular Deaths and Living Controls. A Prospective Study in Evans County, Georgia. (Eng) Heyden, S. (Dept. Community and Family Medicine, Duke Univ. Medical Center, Durham, NC 27710); Heyden, F.; Heiss, G.; Hames, C. G. *J Chronic Dis* 32(9/10): 673-677; 1979.

A study of 2,530 adults (60% white, 40% black) was conducted to determine whether coffee consumption and smoking habits are prospectively related to cancer mortality. Between 1967 and 1969, this population was interviewed about smoking and coffee drinking, and all deaths occurring over the next 10 yr were ascertained. Physical examinations at the start of the study indicated that the study population was free of any manifest or symptomatic cancer. Seventy-four persons died of cancer during the study period. These patients were matched with 74 patients who died of cardiovascular diseases and with 74 healthy survivors. The number of smokers among persons who died of cancer (33/74) was much greater than the number of smokers among healthy controls (22/74). Although the number of smokers in the cardiovascular group (27/74) was greater than in the control group, the difference was not so striking. There were fewer heavy coffee drinkers in the cancer group than in the cardiovascular and control groups, which had identical coffee drinking habits. These results indicate that while cigarette smoking may be related to the co-carcinogenesis in about one-third of the cancer patients, regular coffee drinking shows no relationship with carcinogenesis. (9 refs)

- 79-7178 Cancer Incidence by Marital Status: U.S. Third National Cancer Survey. (Eng) Ernster, V. L. (Dept. Epidemiology and International Health, Univ. California, San Francisco, CA 94143); Sacks, S. T.; Selvin, S.; Petrakis, N. L. *J Natl Cancer Inst* 63(3): 567-585; 1979.

Site-specific cancer incidence rates were computed separately for whites and blacks, aged 35-64 yr, by sex, age, and marital status with the use of population-based incidence data from the Third National Cancer Survey (1969-71) and with demographic data from the 1970 U.S. Census. Although rates were presented for all cancer sites combined and for 44 specific sites or rubrics, discussion focused on the 17 most common cancers. Within age, race, and sex groups, patterns of cancer incidence by marital status were compared by means of standardized incidence ratios, and the consistency of marital status patterns across age groups was assessed statistically. Among the most notable findings were excess cancer rates across most sites and age groups in single black males, consistently high rates for cancer of the lung and bronchus in divorced white males and in single black females, low rates for the hormone-dependent reproductive tumors (prostate gland, breast, uterine corpus, and ovary) in separated white males and females, and high rates for cervical cancer among separated white women. Marital status patterns, where found, frequently differed between whites and blacks and between males and females. (11 refs)

- 79-7179 Lung Cancer in Louisiana: Death Certificate Analysis. (Eng) Gottlieb, M. S. (Dept. Medicine, Tulane Univ. Medical Center, 1430 Tulane Ave., New Orleans,

LA 70112); Pickle, L. W.; Blot, W. J.; Fraumeni, J. F. *J Natl Cancer Inst* 63(5): 1131-1137; 1979.

Death certificates of residents in a cluster of Louisiana parishes (mainly in the southern part of the state), where lung cancer mortality was high, were reviewed. A comparison of the statements on occupation for 3,327 patients with lung cancer and those of 3,327 controls (matched by sex, race, age, and parish of residence) between 1960 and 1975 revealed an approx twofold excess risk associated with transportation equipment manufacture, mainly shipbuilding, and the fishing industry. Smaller elevations of lung cancer risk were found among older men who had been employed in petroleum exploration and production and among male and female residents of towns where the petroleum industry was a major employer. In addition, Acadian ancestry was associated with a higher risk of lung cancer among older men and women. (26 refs)

- 79-7180 Incidence of Nasopharyngeal Carcinoma in Malaysia, 1968-1977. (Eng) Armstrong, R. W. (ICMR, Inst. Medical Res., Univ. California, San Francisco, CA 94143); Kannan Kutty, M.; Dharmalingam, S. K.; Ponnudurai, J. R. *Br J Cancer* 40(4): 557-567; 1979.

The incidence of nasopharyngeal carcinoma (NPC) in Malaysia occurring between 1968 and 1977 was investigated. During this period, there were 2,297 confirmed cases of NPC, 1,335 of which occurred between 1973 and 1977. Age-adjusted incidence rates among Chinese male and female patients were 2.3 and 0.7 per 100,000, and that among Indian male patients was 1.0 per 100,000. There were no significant changes in incidence rates by sex or ethnic group or among the Chinese subethnic groups during the 10-yr period. In the Chinese subethnic groups, rates were highest among the Cantonese, moderate among the Khek, and lowest among the Hokkien and Teochiu. Standardized incidence ratios using Selangor as the standard population indicated considerable under-reporting in the less urban states of Malaysia, particularly among women. In Selangor, incidence rates were similar among urban and rural residents, but the frequency of cases was higher among Chinese working in factories and living in poor neighborhoods. (12 refs)

- 79-7181 Asbestos, Dental X-Rays, Tobacco, and Alcohol in the Epidemiology of Laryngeal Cancer. (Eng) Hinds, M. W. (Cancer Center Hawaii, Univ. Hawaii, 1236 Lauhala, Suite 407, Honolulu, HI 96813); Thomas, D. B.; O'Reilly, H. P. *Cancer* 44(3): 1114-1120; 1979.

A case-control study of 47 laryngeal cancers in males from three Washington state counties was conducted. Personal interview was used to obtain information on smoking, alcohol use, exposure to asbestos and other potentially harmful substances, and x-rays of the head and neck area. Smoking and alcohol consumption were found to increase risk of laryngeal cancer independently, with a clear dose-response relationship. Neither asbestos exposure nor exposure to other substances caused significant increases in the risk of laryngeal cancer, although the relative risk with asbestos exposure was 1.75. Lifetime history of exposure to dental x-rays on five or more occasions was associated with significantly increased risk of laryngeal cancer among heavy smokers but not among light smokers. The importance of tobacco and alcohol in the epidemiology of laryngeal cancer was reaffirmed, the importance of asbestos exposure was brought into question, and a possible

relationship between laryngeal cancer and exposure to dental x-rays among heavy smokers was demonstrated. (22 refs)

- 79-7182 Incidence of *Fusarium* Species and the Mycotoxins, Deoxynivalenol and Zearalenone, in Corn Produced in Esophageal Cancer Areas in Transkei. (Eng) Marasas, W. F. (National Res. Inst. Nutritional Diseases, S. African Medical Res. Council, Tygerberg 7505, S. Africa); van Rensburg, S. J.; Mirocha, C. J. *J Agric Food Chem* 27(5): 1108-1112; 1979.

The highest known esophageal cancer rate in Africa occurs in the southwestern districts of the Republic of Transkei, while the rate in the northeastern region of the country is relatively low. Corn is the main dietary staple in both areas. Three species of *Fusarium*, *F. graminearum*, *F. verticillioides* (= *F. moniliforme*) and *F. sacchari* var. *Subglutinans* (= *F. moniliforme* var. *subglutinans*), were isolated from corn kernels from both areas. Two *Fusarium* mycotoxins, deoxynivalenol and zearalenone, were detected at biologically significant levels (250-4,000 and 1,500-10,000 µg/kg, respectively) in hand-selected, visibly infected corn kernels from both areas. The level of natural contamination of corn kernels with both mycotoxins was considerably higher in the high-incidence area of esophageal cancer than in the low-incidence area. The validity of this difference could not be tested because only a small number of pooled samples were analyzed. (38 refs)

- 79-7183 Gastric Cancer Incidence. Suggestive Evidence for Persisting Effects of Experiences During 1940-1950 (World War II and Postwar Among Eastern European Immigrants to Israel and in Warsaw and Rural Poland. (Eng) Goldsmith, J. R. (Epidemiological Studies Lab., California State Health Dept., Berkeley, CA 94704); Steinitz, R.; Wronkowski, Z. *Front Gastrointest Res* 4: 111-121; 1979.

The hypothesis that the gastric cancer (GC) excess among East European immigrants to Israel might be a reflection of wartime malnutrition was studied. Age-specific incidence rates for GC among migrants from Poland, Rumania, and the Soviet Union resembled comparable rates a decade later for persons living in Warsaw and rural Poland. These rates were higher than those among persons migrating to Israel from other and poorer countries. More recent migrants showed higher age-specific incidence rates than earlier migrants. Among persons aged more than 55 yr, the slope of the age-specific incidence rates with age was steeper than among younger persons. The phenomenon was especially prominent in males and appeared to be related to the relative proportion of "intestinal" type tumors which dominate among Warsaw men aged more than 55 yr. Both immigrants who were in refugee status or concentration camps and the Polish population suffered severe nutritional and other deprivations during and immediately after World War II. A rapid decrease in most of the age-specific rates occurred in both populations during 1963-1972, but

the end of severe nutritional deprivation was in the late 1940's for most of the immigrants and in the early 1950's for the Polish populations. The findings are consistent with persisting effects of experiences during 1940-1950. (20 refs)

- 79-7184 Causes of Death of Blue-Collar Workers at a Dublin Brewery, 1954-73. (Eng) Dean, G. (Medico-Social Res. Board, Dublin, Ireland); MacLennan, R.; McLoughlin, H.; Shelley, E. *Br J Cancer* 40(4): 581-589; 1979.

The suggested association between high consumption of beer and an increased risk of death from cancer of the colon and rectum was investigated among blue-collar workers at a Dublin brewery, who consume more than average amounts of beer, usually in the form of stout. A study of their mortality between 1954 and 1973 showed that they had as good an expectation of life as all Dublin males, with no increased risk of death from cancer of the esophagus, pharynx, liver or from cirrhosis of the liver, accidents or suicide, conditions normally associated with the high consumption of alcohol. Compared with all Dublin males, they had a significantly increased risk of death from cancer of the rectum and also from diabetes mellitus. Within the brewery, the number of deaths from rectal cancer was significantly higher among men who worked in the brewhouse as opposed to other areas. (9 refs)

- 79-7185 Premalignant Lesions of the Cervix in Women of Cali, Colombia. (Eng) Duque, E. (Dept. Pathology, Sch. Medicine, Universidad del Valle, Cali, Colombia); Cuello, C.; Aristizabal, N.; Haenszel, W.; Botero, S.; Correa, P. *J Natl Cancer Inst* 63(4): 953-963; 1979.

A detailed histologic study of the uterine cervix was performed on 441 autopsy specimens from the population of Cali, Colombia, where there is one of the highest registered incidence rates of cancer at this site. The following lesions (in order of prevalence) in adult women: cervicitis, 79%; reserve cell hyperplasia, 14%; squamous metaplasia, 41%; dysplasia, 9%. Contrary to expectations, no correlation was found between increase in prevalence of these lesions and age, lower socioeconomic status, or number of pregnancies. A similar study of a sample of hysterectomies performed for uterine prolapse showed approx the same results. The findings suggest that promoting factors are more important than initiating factors in carcinogenesis of the uterine cervix. (13 refs)

- 79-7186 Somatic Cell Genetic Analysis of Gene Transfer in Mammalian Cells. (Eng) Ruddle, F. H. (Dept. Biology, Yale Univ., New Haven, CT 06520); Fournier, R. E. *Brookhaven Symp Biol* (29): 96-105; 1978.

Studies of gene transfer in mammalian cells are reviewed. In gene transfer experiments, donor chromosomes are ingested by phagocytosis and degraded in lysosomes. In some instances, small fragments of the donor chromosomes avoid destruction and escape from the endocytosis apparatus. These fragments have been termed transgenomes, and their size has been estimated at 2×10^3 - 1×10^6 nucleotide base-pairs. In gene transfer studies, transferred clones could be classified as being either stable or unstable with regard to their capacity to retain the transgenome in the absence of selection pressure for its retention. It was postulated that stability might be associated with integration of the transgenome into the host-cell genome. Specific mapping of the presumed integration sites was performed using the methods of somatic cell genetics in a system in which human cells serve as the donor and mouse cells as the recipient (HuHPRT + MoHPRT-). The results of these experiments supported the hypothesis that in stable transformants, the transgenome is stably integrated into one or more sites in the recipient genome. The data also suggested that integration does not preferentially occur at the homologous locus. The experiments showed only an association between the human transgenome and specific murine chromosomes. Such an association does not provide proof of linear insertion by covalent bonding of donor DNA into host chromosomes. (20 refs)

- 79-7187 Loss of Epidermal Growth Factor Requirement and Malignant Transformation. (Eng) Cherington, P. V. (Lab. Tumor Biology, Sidney Farber Cancer Inst., 44 Binney St., Boston, MA 02115); Smith, B. L.; Pardee, A. B. *Proc Natl Acad Sci USA* 76(8): 3937-3941; 1979.

Serum provides growth factors that regulate and limit the growth of normal cells in tissue culture. Animal cells that are malignantly transformed usually exhibit diminished serum requirements for growth in culture. A defined, serum-free medium was used to determine which of these growth factors becomes dispensable for the growth of transformed Syrian and Chinese hamster fibroblast cells. The medium's four growth factors - epidermal growth factor (EGF), insulin, fibroblast growth factor, and transferrin - were added or omitted as desired. A decreased requirement for EGF was most closely related to tumorigenicity of chemically (ethylmethanesulfonate) transformed cells in nude mice. All lines examined retained their requirement for transferrin, which is needed throughout the growth cycle, in contrast to the other factors, which are needed primarily in the G₁ phase. Lines that had lost their EGF requirement but had retained their insulin requirement were arrested in G₁ by insulin deficiency, indicating that their growth control system remained. Mutagenesis with ethyl methanesulfonate can also create requirements of the transformed cells for unknown factors in serum. It is concluded that an initial step that reduces the serum requirement in culture, and in tumorigenesis, is relaxation of the growth-regulatory function of EGF. (31 refs)

- 79-7188 Significance of Specific-Locus Germ-Cell Mutations in Mice. (Eng) Bateman, A. J. (Paterson Labs., Wilmslow Rd., Manchester, England). *Mutat Res* 64(5): 345-351; 1979.

The numerical requirements of the specific-locus germ-cell mutagenicity test in the laboratory mouse were analyzed. This is the most appropriate test for the detection of gene mutations in the germ cells of a mammal, is technically simple, but requires many animals to obtain significant results. On the basis of a historical-control incidence of 39 mutants in 688,921 progeny (0.82 mutations/locus/ 10^6 gametes), it is recommended that 25,000 control progeny be included in each test. This would also be the number required from treated males, unless significantly positive results had been obtained with smaller numbers: 1 mutant in <900 progeny, 2 in <6,300, 3 in <14,500, or 4 in <24,000. In any of these events, mutagenic activity would be established in the treated series, provided that the control series comprised 25,000 with <4 mutants. Analysis of one series of mutagenicity tests indicated that post-spermatogonial stages (especially postmeiotic stages) are very sensitive to mutagens. This high sensitivity may make the post-spermatogonial stages, in spite of technical difficulties in sampling, more suitable than the spermatogonial stage for the detection of mutagens, but not for quantitative studies. (4 refs)

- 79-7189 Human Chorionic Gonadotropin α -Subunit from Cultured Choriocarcinoma (JEG) Cells: Comparison of the Subunit Secreted Free with That Prepared from Secreted Human Chorionic Gonadotropin. (Eng) Benveniste, R. (Gynecological Endocrinological Labs., Dept. Obstetrics and Gynecology, Michael Reese Medical Center, Univ. Chicago, Chicago, IL 60616); Lindner, J.; Puett, D.; Rabin, D. *Endocrinology* 105(3): 581-587; 1979.

The human chorionic gonadotropin α -subunit (JEG- α) secreted free from cultured choriocarcinoma (JEG) cells was compared with the α -subunit prepared from secreted human chorionic gonadotropin (hCG). Free JEG- α had an apparent mol wt larger than either JEG-hCG- α or standard hCG- α , the latter two being similar. JEG- α contained a major component of pI 4.8 (acid isoelectric pH) that was not present in the α -subunits derived from JEG-hCG or standard hCG. In tests of recombination with the β -subunit of hCG, freely secreted JEG- α appeared nearly incapable of forming radioreceptor assay-active hCG. A kinetic study of in vitro hCG formation over a 24-hr period confirmed that standard hCG- α and JEG-hCG- α have the ability to form an hCG which competes with hCG tracer, as contrasted with the inability of JEG- α to do so. JEG- α appeared unable to combine with standard hCG- β . These data suggest that JEG cells secrete an α -subunit in the free state that is different from the "normal" hCG α -subunit secreted by and incorporated into these same cells, as well as from that of the hCG secreted in pregnancy. (37 refs)

- 79-7190 Tumor-specific DNA Sequences in Human Gliomas. (Eng) Cuatrecasas, W. (P.O. Box 1666, Idaho Falls, ID 83401); Cho, J. R. *Cancer* 44(4): 1309-1314; 1979.

By hydroxyapatite chromatography, normal cellular DNAs were used to recycle off the repeat or normal sequences found in [3 H]DNA copied off 70S RNA from malignant human astrocytomas. The recycled DNA was then used to hybridize with DNA from normal human brain tissues and DNAs from malignant or grade IV astrocytomas. About 60%-70% of the sequences found in the 70S DNAs were normal or repeat sequences. An 88% hybridization was achieved with DNAs from malignant astrocytomas and recycled 70S DNA probes from malignant astrocytomas. Only 7% hybridization was obtained using normal brain tissue DNA. When recycled medulloblastoma 70S DNA probes were used, the percent hybridization was 67% with Grade IV astrocytoma DNA and 7% with normal brain tissue DNA. The data indicate that malignant human gliomas contain tumor-specific DNA sequences that are absent from normal brain tissues and suggest that the presence of these sequences signifies the existence of a neoplastic process. - 79-7191 Differences in the Distribution of Poly(A) Size Classes in Individual Messenger RNAs from Neuroblastoma Cells. (Eng) Morrison, M. R. (Leland Fikes Lab. Cellular Neurobiology, Dept. Neurology, Univ. Texas Health Science Center at Dallas, Dallas, TX 75235); Brodeur, R.; Pardue, S.; Baskin, F.; Hall, C. L.; Rosenberg, R. N. *J Biol Chem* 254(16): 7675-7683; 1979.

The adenylated and nonadenylated messenger RNA (mRNA) populations in neuroblastoma cells were studied. Neuroblastoma polysomal mRNAs were fractionated into four classes containing poly(A) of different av lengths, using oligo(dT)-cellulose and Millipore filter techniques. Quantitation of the biological activity of each fraction in a wheat germ translation system showed that 32% of the mRNAs contained no oligo(A)s longer than 6 nucleotides, 4% had poly(A)s between 6 and 20 nucleotides, 22% had poly(A)s between 20 and 50 nucleotides, and 42% had poly(A)s with >50 nucleotides. Most mRNAs were found in each of the four size class populations, although the distribution of some individual mRNAs varied widely. The α - and β -tubulin mRNAs were more abundant in the population with long poly(A)s, whereas a significant proportion of the mRNAs coding for actin and the R₁ and R₂ cAMP-binding proteins were nonadenylated. The histone mRNAs were unique in that they were more abundant in nonadenylated mRNAs than in mRNAs containing short stretches of poly(A). The results suggest that the poly(A) termini in some mRNA species are cleaved more rapidly than those in others. (51 refs)

- 79-7192 Effect of Temperature on Protein and Immunoglobulin Synthesis and Secretion in Two Mouse Myeloma Cell Lines. (Eng) Craig, N. (Dept. Biological Sciences, Univ. Maryland Baltimore County, Catonsville, MD 21228). *J Cell Physiol* 100(2): 323-334; 1979.

Protein synthesis was studied in differentiated MOPC-21 and MPC-11 mouse myeloma cells to determine the basis for differences in temperature and actinomycin D sensitivity of translation between nondifferentiated mouse L-cells and differentiated rabbit reticulocytes. The temperature dependence of total protein synthesis was similar to that of L-cells and reticulocytes, being biphasic in Arrhenius plots with apparent activation energies of approx 25 and 42 kcal/mol, above and below 25 C. The dependence of the secretion process was different, since it was not biphasic, having a single activation energy of about 22 kcal/mol.

Myeloma polysomes were like L-cell polysomes in their response to lower temperature and reached a minimum level of 50% at 15 C. This response was also found for the specific polysomes synthesizing the IgG H- and L-chains. In the presence of actinomycin D, myeloma polysomes declined exponentially with a half-life of approx 6 hr. These two L-cell-like responses were not found in reticulocytes. Translation of both the IgG messenger RNAs (mRNAs) and the non-IgG mRNAs was reduced by lower temperatures and actinomycin D, even though the L-chain mRNA was slightly more resistant, suggesting that this mRNA is slightly more efficient. The results suggest that the translational differences between L-cells and reticulocytes are not mRNA dependent, but are cell type differences. (25 refs)

- 79-7193 Suppression of Granulopoiesis in Diffusion Chambers by Syngeneic Clonal Acute Myelogenous Leukemia Cells or Peritoneal Exudate Macrophages. (Eng) Franklin, K. W. (Div. Hematology, Peter Bent Brigham Hosp., Boston, MA); Moloney, W. C.; Greenberger, J. S. *Acta Haematol (Basel)* 61(6): 317-324; 1979.

To determine the mechanism by which acute myelogenous leukemia (AML) cells suppress normal marrow granulopoiesis, diffusion chambers containing Wistar/Furth (W/Fu) rat marrow cells, peritoneal exudate (PE) macrophages or W/Fu AML clone-3 cells were implanted ip into syngeneic irradiated rats. Growth of each population over 21 days in single or double diffusion chambers (in which cell populations were separated by a Nucleopore filter) was compared to that of mixed populations. Double diffusion chamber culture of homologous or heterologous combinations had no detectable effect on growth kinetics of any of the three cell populations as compared to single chambers. In contrast, normal granulocyte proliferation was significantly depressed by single-chamber cocultivation with equal or 10-fold lower numbers of PE macrophages or AML cells. Mixing PE macrophages with AML cells produced no preferential population suppression. AML cell differentiation was not detected under any set of conditions. These studies demonstrate that physical contact with proliferating normal macrophages as well as AML cells will suppress granulopoiesis in diffusion chambers. (26 refs)

- 79-7194 The Role of RNA and Protein Synthesis in Mediating the Action of MSH on Mouse Melanoma Cells. (Eng) Fuller, B. B. (Dept. General Biology, Univ. Arizona, Tucson, AZ 85721); Viskochil, D. H. *Life Sci* 24(26): 2405-2415; 1979.

Exposure of mouse melanoma cells in culture to MSH (melanocyte stimulating hormone) resulted in a marked increase in tyrosinase (O-diphenyl: O₂ oxidoreductase) activity following a lag period of 6-9 hr. Within 20 min after exposure of cells to MSH, the intracellular levels of cyclic AMP (cAMP) rose to levels ten times those of controls; cAMP levels then fell to twice control values by 60 min. Transient increases in rates of both protein and RNA synthesis also occurred following MSH administration and correlated in time with the dramatic but rapidly decaying increase in cellular cAMP. The increase in tyrosinase activity observed in response to either MSH, dibutyl cAMP, or theophylline was completely suppressed by the addition of either cycloheximide (0.28 μ g/ml) or actinomycin D (0.05 μ g/ml), as was the basal activity of the enzyme. Results from 14 C/ 3 H leucine studies suggest that MSH may cause increased de novo synthesis of tyrosinase. (14 refs)

- 79-7195 Incorporation of L-3,4-Dihydroxy-(2-¹⁴C)Phenylalanine into Hamster Melanoma Melanosomes. (Eng) Borovansky, J. (Dept. Chemistry and Biochemistry, Faculty General Medicine, Charles Univ., U nemocnice 5, 128 53 Prague 2, Czechoslovakia); Pavel, S.; Duchon, J.; Vulterin, K. *FEBS Lett* 104(2): 291-293; 1979.

Six Syrian hamsters bearing a transplantable Bomirski melanoma, pigmented line Ma (180th passage), were given radiolabeled L-3,4-dihydroxyphenylalanine [(2-¹⁴C)Dopa] ip and killed 4 days later. The amount of melanin in melanosomes isolated from the tumors was determined by acid hydrolysis, and radioactivity was measured by liquid scintillation spectrometry. The melanosome pellet contained about 16% of the original radioactivity. (2-¹⁴C)Dopa seemed to be tightly bound to the melanosomes. Extraction with water and exchange diffusion released no significant amount of radioactivity. However, after hydrolysis 12% of radioactivity could be detected in the hydrolyzate. These results indicate that on a subcellular level Dopa is selectively taken up by melanosomes. (25 refs)

- 79-7196 Glutamine-Phosphoribosylpyrophosphate Amidotransferase (Amidophosphoribosyltransferase, EC 2.4.2.15) Activity in Normal, Differentiating, and Neoplastic Kidney. (Eng) Prajda, N. (Lab. Experimental Oncology, Indiana Univ. Sch. Medicine, Indianapolis, IN 46223); Morris, H. P.; Weber, G. *Cancer Res* 39(10): 3909-3914; 1979.

The activity of glutamine-phosphoribosylpyrophosphate amidotransferase (GPA) in normal differentiating, and neoplastic (following sc transplantation of renal cell tumors) kidney was studied in male Buffalo, male ACI/N, and Wistar rats. In normal kidney cortex and in the MK-3 renal cell tumor, the pH optimum of GPA was 7.2-8.5; the Michaelis constants for glutamine were 2.0 and 1.7 mM, respectively, and the Km for MgCl₂ was 1 mM. For kidney and tumor phosphoribosylpyrophosphate, the affinities were 0.9 and 0.5 mM, respectively. The amidotransferase in the kidney showed sigmoid kinetics for phosphoribosylpyrophosphate. The 50% feedback inhibition by adenosine 5'-monophosphate of the GPA in normal kidney and in MK-3 tumor were 9.5 and 9.3 mM, respectively. The GPA-specific activities in rat thymus, testis, bone marrow, gut, kidney cortex, spleen, lung, brain, adipose tissue, heart, and skeletal muscle were 271%, 259%, 173%, 167%, 128%, 98%, 70%, 64%, 49%, 24%, and <1.0%, respectively, of that in the liver. In three transplantable renal tumors (MK-1, MK-2, and MK-3), the GPA-specific activities were increased 2.2- to 2.7-fold over that of the normal kidney cortex. During development, the av enzyme activities of 1-, 7-, 30-, and 40-day-old rats were 57%, 71%, 79%, and 114% of those in adult kidney. Elevated GPA activity should increase the capacity of the de novo purine biosynthetic pathway, and the enzyme imbalance should confer selective advantages to neoplastic cells. (37 refs)

- 79-7197 Two Major Regulatory Steps in Cholesterol Synthesis by Human Renal Cancer Cells. (Eng) Gonzalez, R. (Dept. Urologic Surgery, Univ. Minnesota, Minneapolis, MN 55455); Carlson, J. P.; Dempsey, M. E. *Arch Biochem Biophys* 196(2): 574-580; 1979.

Cholesterol synthesis was studied in a human cell line (Caki-1) established from a kidney clear cell carcinoma metastatic to skin. Exogenous cholesterol (30 µg/ml) added to the Caki-1 culture

medium decreased the activity of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase from 270 picomoles (pmol)/min/mg with lipoprotein-poor serum to 82 pmol/min/mg. There was a rapid increase in the activity of HMG-CoA reductase when cholesterol was removed. Exogenous cholesterol decreased the incorporation into cholesterol of three labeled precursors (water, acetate, and mevalonate) three- to fivefold compared to the maximum incorporation observed in lipoprotein-poor serum. While the inhibition of cholesterol synthesis from acetate and water may be explained by the observed decrease in the activity of HMG-CoA reductase, this explanation does not hold for mevalonate. The decrease in cholesterol levels was accompanied by an increase in squalene, which suggests inhibition of cholesterol synthesis from mevalonate at the level of squalene epoxidase. Cholesterol in the presence of lipoprotein-free serum was nearly as effective as lipoprotein-bound cholesterol in lowering HMG-CoA reductase activity and blocking the conversion of acetate and mevalonate to cholesterol. The occurrence of two major mechanisms regulating cholesterol synthesis may be a unique property of renal cancer cells or a previously unrecognized general property of many cells in culture. (29 refs)

- 79-7198 Serum, Pituitary and Urine Concentrations of Prolactin and Growth Hormone in Eight Strains of Mice with Varying Incidence of Mammary Tumors. (Eng) Sinha, Y. N. (Lutcher Brown Center for Diabetes and Endocrinology, Scripps Clinic and Res. Foundation, La Jolla, CA 92037); Vlahakis, G.; VanderLaan, W. P. *Int J Cancer* 24(4): 430-437; 1979.

Eight inbred strains of mice with varying incidences of spontaneous mammary tumors were compared for prolactin and growth hormone concentrations in sera, pituitary glands, and urine. Serum prolactin was compared under basal conditions as well as after stimulation with perphenazine. Both hormones were measured with specific, homologous radioimmunoassays. Although some strains having a high incidence of mammary tumors had high levels of prolactin, neither basal nor perphenazine-induced serum concentrations showed a consistent pattern that correlated with tumor incidence across mouse strains. Growth hormone levels in sera, pituitary glands, and urine also had no characteristic pattern that applied to all strains studied. The ratio of prolactin depleted from the pituitary gland to prolactin detected in serum after perphenazine injection, a reflection of the metabolic clearance rate of prolactin, was highest in two strains with a high incidence of mammary tumors and relatively lower in low-tumor strains. These results suggest that if prolactin does play a part in mammary tumor development in mice, its mechanism varies from strain to strain: while hyperprolactinemia may be the means in some strains, a peculiarity in the metabolism of the hormone may be more important in others. (28 refs)

- 79-7199 Acid Mucopolysaccharides in Mammary Tumors of Dogs. (Eng) Palmer, T. E. (Raltech Scientific Services, Inc., P. O. Box 7545, Madison, WI 53707); Monlux, A. W. *Vet Pathol* 16(5): 493-509; 1979.

Thirty-four canine mammary tumors were studied histochemically for acid mucopolysaccharide content. The tumors included ductal carcinomas (17), intraductal carcinomas (5), lobular carcinomas (2), adenomas (6), and ductal papillomas (4). Acid mucopolysaccharides of various staining intensities were seen in all tumors. The most deeply stained zones were found in cartilaginous areas. Difference in staining intensity suggested a transition from ac-

accumulated acid mucopolysaccharides to mature hyaline cartilage. Most of the mucopolysaccharides were alcian blue-positive at pH 2.5, weakly alcian blue-positive or negative at pH 1.0, periodic acid-Schiff negative, labile to hyaluronidase digestion, and stable to neuraminidase digestion. According to these characteristics, the substances were hyaluronic acid, chondroitin-4-sulfate, and chondroitin-6-sulfate. The acid mucopolysaccharides identified in the canine mammary tumors were derived from stromal or mesodermal tissues and were identical to those found in the ground substance of the matrix of normal developing hyaline cartilage. Neither the specific cell of origin nor the stimulus for acid mucopolysaccharide production in the tumors was identified. (40 refs)

79-7200 Growth of a Human Mammary Tumour Cell Line in a Serum-free Medium. (Eng) Barnes, D. (Dept. Biology Q-058, Univ. California, San Diego, La Jolla, CA 92093); Sato, G. *Nature* 281(5730): 388-389; 1979.

The growth of a human mammary tumor cell line, MCF-7, in a serum-free medium is described. MCF-7 cells could be grown, without a lag or adaptation phase, in serum-free medium supplemented with physiological levels of insulin, transferrin, epidermal growth factor (EGF), prostaglandin $F_{2\alpha}$ ($PGF_{2\alpha}$), and cold-insoluble globulin (CIg). Insulin was the most important component of the defined medium. The maximal effect of insulin was observed with 100-300 nanograms (ng)/ml with a measurable effect at 3 ng/ml. Transferrin produced a maximal stimulation at 25 μ g/ml and CIg at 7.5 μ g/ml. $PGF_{2\alpha}$ was maximally stimulatory at 100 ng/ml and EGF at 10-100 ng/ml. Cells in serum-free medium with the five factors grew as rounded clumps that were poorly attached to the dish. The addition of α -1 serum protein greatly improved attachment and spreading of MCF-7 in the serum-free medium at <1 μ g/ml. Although it is possible that long-term cultivation of MCF-7 cells in this serum-free medium may expose additional requirements for other hormones, the cells have been successfully carried for 3 mo (15 passages) in the serum-free medium. LIBRARY U. OF I. URBANA - CHAMPAIGN

Subject Index

Abdominal Neoplasms

- Angiosarcoma
 - Azobenzene, 79-6766
- Fibrosarcoma
 - Azobenzene, 79-6766
- Sarcoma, Osteogenic
 - Azobenzene, 79-6766

Abnormalities

- Hyperthermia
 - Hamster, 79-6900
- Retinol
 - Hamster, 79-6900
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Vagina, Cervix, 79-7174

Acetaldehyde

- Anemia, Aplastic
 - Sister-Chromatid Exchange, 79-6661
- Benzo(a)pyrene
 - Co-carcinogenic Effect, 79-6678
- Diethylamine, *N*-Nitroso-
 - Co-carcinogenic Effect, 79-6678

Acetaldehyde, Chloro-

- Ether, Bis(2-chloroethyl)-
 - Hepatocarcinogenesis, 79-6739

Acetamide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-

- Acetohydroxamic Acid, *N*-4-Biphenyl-, Potassium Salt
 - DNA Substitution Products, 79-6680
- Caffeine
 - Cell Transformation, Neoplastic 79-6891
- DNA
 - Nucleic Acid Denaturation, 79-6691
- DNA Repair
 - Fibroblasts, 79-6873
 - Nucleotides, 79-6873
- Guanosine, 2'-Deoxy-
 - Endonucleases, 79-6691
- RNA Adducts
 - Liver, Rat, 79-6848
- Ultraviolet Rays
 - Cell Transformation, Neoplastic 79-6891
- Xeroderma Pigmentosum
 - DNA Repair, 79-6873

Acetamide, *N*-(4-(1,2-Dihydroxy-2-phenylethyl)phenyl)-4-Stilbenamine, *N,N*-Dimethyl-RNA Adducts, 79-6848

Acetamide, *N*-Fluoren-2-yl-

- Cholanthrene, 3-Methyl-
 - Microsomes, Liver, 79-6685
- Chromatids
 - Bone Marrow, 79-6686
 - Liver Regeneration, 79-6686
- Chromosome Aberrations
 - Mutagenic Metabolite, 79-6744
- Glucosephosphate Dehydrogenase
 - Enzymatic Activity, 79-6682
- Hepatoma
 - Chromosomal Proteins, Non-Histone 79-7122
 - Hyperplasia, 79-7123
 - Precancerous Conditions, 79-7123
- Hyperplasia
 - Barbituric Acid, 5-Ethyl-5-phenyl- 79-6687
 - 5,6-Benzoflavone, 79-6687
 - Cholanthrene, 3-Methyl-, 79-6687
 - Kanechlor 500, 79-6687
- Liver Neoplasms
 - Hyperplasia, 79-6684, 79-6688
 - 2,4-Oxazolidinedione, 3-(3,5-Dichlorophenyl)-5,5-dimethyl- 79-6687
 - Precancerous Conditions, 79-6687
 - Selenium, 79-6685
 - Serine, Diazoacetate (Ester), 79-6683

Acetamide, *N*-Fluoren-2-yl- (cont'd)

- Phosphoglucanate Dehydrogenase
 - Enzymatic Activity, 79-6682
- Selenium
 - Metabolism, 79-6685
 - Microsomes, Liver, 79-6685
- 4,4'-Stilbenediol, α,α' -Diethyl-
 - Ames Test, 79-6679

Acetanilide, 4'-(*p*-Fluorophenyl)-

- Adenocarcinoma
 - Acetic Acid, Lead Salt, 79-6689
- Cytochrome P-450
 - Liver, Rat, 79-6689
- Hepatoma
 - Acetic Acid, Lead Salt, 79-6689
- Kidney Neoplasms
 - Adenocarcinoma, 79-6689

Acetanilide, 4'-Hydroxy-

- Carcinogenic Metabolite
 - Liver, Review, 79-6616

Acetic Acid, Lead Salt

- Adenocarcinoma
 - Acetanilide, 4'-(*p*-Fluorophenyl)- 79-6689
- Calcium
 - Chromosome Aberrations, 79-6646
- Hepatoma
 - Acetanilide, 4'-(*p*-Fluorophenyl)- 79-6689
- Kidney Neoplasms
 - Adenocarcinoma, 79-6689

Acetic Acid, Methylnitrosaminomethyl Ester

- Esterases
 - Metabolism, Rat, 79-6865
- Guanine, 7-Methyl-
 - Organ Specificity, 79-6865
- Phosphorofluoridic Acid, Bis(1-methylethyl) Ester
 - DNA, Alkylation, 79-6865

 A-Type Particles, 79-7053, 79-7054

Virus, Newcastle Disease
 Antigens, Viral
 Immunologic Technics, 79-7061
 Lymphoma
 Cell Membrane, 79-7061
 Membrane Proteins
 Hemolysis, 79-7061

Virus, Papilloma
 DNA, Viral
 Nucleotide Sequence, 79-6996
 Skin Neoplasms
 Genetics, 79-7030
 Virus, Bovine Papilloma
 Nucleic Acid Homology, 79-6996
 Virus, Shope Rabbit Papilloma
 Nucleic Acid Homology, 79-6996

Virus, Papova
 Paraganglioma
 DNA, Viral, 79-7020
 Isolation and Characterization
 79-7020

Virus, Pheasant RNA Tumor
 DNA Polymerase
 Antigenic Determinants, 79-6956
 Radioimmunoassay, 79-6956
 Virus, Avian Leukosis
 Antigenic Determinants, 79-6956

Virus, Polyoma
 Antigens, Neoplasm
 Cell Membrane, 79-7029

Virus, Polyoma(cont'd)
 Nucleotide Sequence, 79-7024
 Cell Transformation, Neoplastic
 Deletion Mutants, 79-7021, 79-7026
 DNA Restriction Enzyme
 Deletion Mutants, 79-7026
 DNA, Viral
 Antigens, Neoplasm, 79-7021
 Binding Sites, 79-7025
 Deletion Mutants, 79-7021, 79-7023
 Nucleic Acid Conformation, 79-7022
 Nucleotide Sequence, 79-7024
 RNA, Messenger, 79-7024
 Membrane Proteins
 Cell Transformation, Neoplastic
 79-7029
 RNA, Messenger
 Deletion Mutants, 79-7023
 DNA-RNA Hybridization, 79-7022
 79-7027
 RNA, Viral
 DNA-RNA Hybridization, 79-7027
 Viral Proteins
 Binding Sites, 79-7025
 Virus, Influenza
 Antineoplastic Activity, 79-7028
 Virus Replication, 79-7028

Virus, Polyoma, BK
 DNA, Viral
 Nucleotide Sequence, 79-7031
 Medulloblastoma
 Histologic Study, Hamster, 79-7033
 Virus, Adeno 7
 Virus, Helper, 79-7032
 Virus Replication
 CV-1 Monkey Cells, 79-7032
 Virus, SV40
 Antigenic Determinants, 79-7032
 Nucleic Acid Homology, 79-7031

Virus, Radiation Leukemia
 Lymphoma
 Virus, Helper, 79-7056
 Virus, C-Type RNA Tumor
 Virus Replication, 79-7056

Virus, Rat Leukemia
 RNA, Messenger
 Stress, Anaerobic, 79-6994
 Virus Replication, 79-6994

Virus, Rauscher Murine Leukemia
 Amino Acids
 Binding Sites, 79-6992
 Antigenic Determinants
 Immunity, Cellular, 79-6991
 Glycoproteins
 Binding Sites, 79-6992
 Cell Membrane, 79-6992
 Histocompatibility Antigens
 T-Lymphocytes, 79-6991
 Viral Proteins, 79-6991
 Leukemia
 T-Lymphocytes, 79-6980
 T-Lymphocytes
 Immunity, Cellular, 79-6980
 Phosphoproteins
 Amino Acids, 79-6990
 Viral Proteins
 Antigenic Determinants, 79-6990

Virus, Recombinant
 Virus, Avian Leukosis
 Subgroup E, 79-6927
 Viral Proteins, 79-6927
 Virus, Murine Leukemia
 Inactivating Factor, 79-7001
 Virus, Rous Sarcoma
 Nucleotide Sequence, 79-6943

Virus Replication
 Carcinoma, Ductal
 Virus, Murine Mammary Tumor
 79-6968
 Glioma
 Virus, Simian Sarcoma, 79-7004
 HeLa Cells
 Virus, Simian Sarcoma, 79-7004

Virus Replication (cont'd)
